Lecture – 47
Perturbation theorem for singular values

Hello friends, welcome to this lecture. Here in this lecture we will continue our study of singular value decomposition. If you recall in previous class in previous lecture of single value decomposition we have seen that the singular values of a any matrix A is well posed.

(Refer Slide Time: 00:48)

(Perturbation Theorem for Singular Values)

Theorem

Let A and $B = A + E$ be two real $m \times n$ matrices, where $m \geq n$. Let $\sigma_i, i = 1, 2, \dots, n$ and $\tau_i, i = 1, 2, \dots, n$ be the singular values of A and B , respectively, in nonincreasing order. Then

$$|\tau_i - \sigma_i| \leq \|B - A\|_2, \quad \forall i = 1, 2, \dots, n.$$

IIIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 2

So, here we have discussed this theorem that let A and B where B is can be written as A plus E, E is considered to be a perturb perturbation matrix to this matrix A, be two real m cross n matrix, where m is greater than equal to n. And let sigma i, i from 1 to n and tau i i from 1 to n with a single values of A and B respectively. And it is arranged in non increasing order then modulus of tau i minus sigma i is less than or equal to 2 norm of B minus A and this is true for every i from 1 to n.

So, this is the result which we have discussed in previous class and we say that the that if we perturbed our matrix A by this matrix E then the eigen values of be singular values of B and a is differed by 2 norm of this perturb matrix E. So, in a the similar kind of result we can also state in terms of Frobenius norm.

(Refer Slide Time: 01:47)

(Perturbation Theorem for Singular Values)

Theorem
Let A and $B = A + E$ be two real $m \times n$ matrices, where $m \geq n$. Let $\sigma_i, i = 1, 2, \dots, n$ and $\tau_i, i = 1, 2, \dots, n$ be the singular values of A and B , respectively, in nonincreasing order. Then

$$\sqrt{\sum_{i=1}^n (\tau_i - \sigma_i)^2} \leq \|B - A\|_F = \|E\|_F$$

For proof one may see the book "Matrix Analysis", Cambridge University Press by Horn and Johnson 1996, page 419.

The result basically states that the singular values of a matrix are well conditioned.

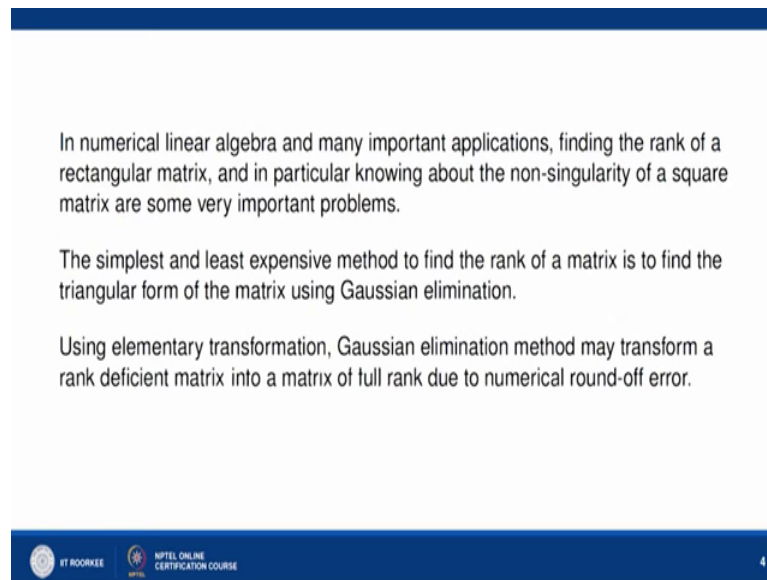

VT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 3

So, the similar kind of result which we state in this theorem that let A and B , where B is A plus E be two real m cross n matrices, where m is greater than equal to n . Let σ_i, i from 1 to n and τ_i from i from 1 to n be the singular values of A and B respectively and it is arranged in non increasing order then under root of summation i equal to 1 to n τ_i minus σ_i square is bounded above by norma Frobenius norm of B minus A . And here Frobenius norm of B minus A is nothing but the Frobenius norm of the perturbation matrix that is this E . So, it means that into Frobenius norm this is bounded by the Frobenius norm of the perturbation matrix.

Here we are not providing any proof and if you want to see the proof of this theorem then we refer the book matrix analysis published by Cambridge University Press, and written by Horn and Johnson in the year 1996 and at page number 419 you can see the proof of this theorem.

And since we have already seen the proof here and we say that the similar kind of proof we can produce for this theorem. And the purpose of studying these two theorems is the following that the result basically state that the singular values of a matrix are well conditioned. So, it means that if you perturb your matrix your singular values will not change much.

(Refer Slide Time: 03:37)

In numerical linear algebra and many important applications, finding the rank of a rectangular matrix, and in particular knowing about the non-singularity of a square matrix are some very important problems.

The simplest and least expensive method to find the rank of a matrix is to find the triangular form of the matrix using Gaussian elimination.

Using elementary transformation, Gaussian elimination method may transform a rank deficient matrix into a matrix of full rank due to numerical round-off error.

IFT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 4

Now, with the help of the last result let us discuss some more important results. So, here we start with this that in numerical linear algebra and many important applications finding the rank of a rectangular matrix or in particular find finding the rank of a square matrix means, whether a square matrix is a singular or nonsingular is these problems are very very important problems. And we take will these problems of finding the rank of a given matrix by using the Gaussian elimination method and in Gaussian elimination method we use elementary row transformation to convert a given matrix into a triangular matrix.

And in, but theoretically it is a very convenient method to find out the rank of a matrix. But if we consider this the same situation in practical life then it is a very it may create a lot of problem the problem is because of this you will elementary transformation and this using elementary transformation Gaussian elimination method may transform a rank deficient matrix into a matrix of full rank due to numerical round off error. So, this is a fact which is very very important and we already know that the matrix which we are considering a may is already perturb or may be polluted by the equipment error or many other error

So, it means that there we are we are never sure that the matrix we are handling is the actual matrix are a perturb matrix. So, we cannot ignore these kind of thing that this elementary row transform may convert a rank deficient matrix into a rank full rank

matrix. So, to avoid these kind of thing we take the help of singular value decomposition to find out the rank of a given matrix A.

(Refer Slide Time: 05:47)

Example

Consider a matrix of size $n \times n$

$$A = \begin{pmatrix} 1 & -1 & \cdots & -1 \\ 0 & 1 & \ddots & -1 \\ \vdots & \ddots & \ddots & -1 \\ 0 & \cdots & 0 & 1 \end{pmatrix}.$$

We may check that the $\text{cond}_{\infty}(A) = n2^{n-1}$ and hence, A is very close to a singular matrix when n is large.

ET ROORKEE NPTEL ONLINE CERTIFICATION COURSE 5

And for example, if you look at this matrix here, where A is a matrix of size n cross n and it is a upper triangular matrix. So, the diagonal elements are one and the all the other element in same in the triangular part is minus 1. So, upper above diagonal entries are minus 1 and the lower diagonal entries are simply 0. So, it is basically a upper triangular matrix whose diagonal entries are 1 1 1 1.

So, it looks that this matrix is a nonsingular matrix and it is nowhere apparent that this matrix is very very near to a singular matrix how we can check that if you look at the condition number of this matrix and the infinity norm and it is you can check that it is coming out to be n times 2 to power n minus 1. And hence you can say that for large size n this condition number is very very large number and hence we can say that by the property of condition number we can say that A is very close to a singular matrix when n is large.

So, it means that handling since you can say that this matrix you can obtain from a any matrix using not any matrix for a given matrix using Gaussian elimination method and here looking at this a we are not able to find out whether this matrix A is very near to a singular matrix or not. So, looking at all these drawbacks that a the matrix given in hand A is a original matrix or a polluted matrix or due to numerical round off error this

Gaussian elimination may convert a rank deficient matrix to a full rank matrix, and even in a triangular form we really do not know whether a given matrix is near to a rank deficient matrix or not we prefer to use SVD, single value decomposition method.

Now, since the number of nonzero singular value determine the rank of a matrix we may say that a matrix A is arbitrary close to a matrix of full rank by changing all these 0 singular values by a very small number say epsilon which is very very small and it is positive, any nonzero number we can say. Then you have a same matrix and it may have some 0 singular values, you change your singular values by an arbitrary small number say epsilon and then this matrix is A changed matrix is a full a matrix of full rank, and you can say that it is arbitrary close to the given matrix.

So, in practical it is more important to know if a matrix is near to matrix of a certain rank rather than knowing the rank of the given matrix. And the singular value decomposition may exactly answer this query. The most useful way to determine the rank and nearness to rank deficient matrix is to use the SVD. So, we try to verify the these statement by same methods.

(Refer Slide Time: 09:14)

(Eckart - Young Theorem)

Theorem

Let $A = USV^T$ be the SVD of a real $m \times n$ matrix A, where $m \geq n$. Let the rank of A be r . Let $\sigma_1 \geq \sigma_2 \geq \dots \geq \sigma_r > 0$ be the positive singular values of A. For,

$k = 1, 2, \dots, r - 1$, define $A_k = US_kV^T$, where $S_k = \begin{bmatrix} \sigma_1 & & & & \\ & \sigma_2 & & & \\ & & \ddots & & \\ & & & \sigma_k & \\ & & & & 0 \end{bmatrix}$.

Then,

(1) $\text{rank}(A_k) = k$.

(2) Let B be any matrix of rank k, then $\|A - B\|_F \geq \|A - A_k\|_F$, or

$\min_{\text{rank}(B)=k} \|A - B\|_F = \|A - A_k\|_F$

7

So, first result in this direction is the following theorem which is Eckart young theorem and given by Eckart and young in 1936. The statement of theorem says that, let A is equal to USV transpose be the singular value decomposition of a real m cross n matrix A, where m is greater than equal to n and we let us assume that the rank of this matrix A is r

and $\sigma_1 \geq \sigma_2 \geq \dots \geq \sigma_k > 0$ which are the positive singular values of A .

Now, for k ranging between $1, 2, \dots, r$ we can define A_k as US_kV^T where this matrix S_k is given by this diagonal matrix where the first k diagonal elements are $\sigma_1, \sigma_2, \dots, \sigma_k$ and rest are all 0s. Wait, then we say that we claim that rank of A_k is k and if we have any matrix B of rank k then Frobenius norm of $A - B$ is greater than or equal to Frobenius norm of $A - A_k$.

So, it means that if you calculate the Frobenius norm of $A - B$, where B is any matrix of rank k then the Frobenius norm of this is always bigger than or equal to Frobenius norm of $A - A_k$. And you can say that the equality you can achieve that it means that and minimum of rank B is equal to k norm Frobenius norm of $A - B$ is a Frobenius norm of $A - A_k$. So, it means that the equality achieved when B is equal to A_k .

(Refer Slide Time: 11:09)

Proof.

Since $A_k = US_kV^T$ is the SVD of A_k , it is obvious that A_k has rank k . Let B be any $m \times n$ matrix of rank k . We will prove that

$$\|A - B\|_F^2 \geq \|A - A_k\|_F^2.$$

Since B has rank k , let the singular values of B be

$$\tau_1 \geq \tau_2 \geq \dots \geq \tau_k \geq 0 = \tau_{k+1} = \dots = \tau_n = 0.$$

So, we have

$$\|A - B\|_F^2 \geq \sum_{i=1}^n (\sigma_i - \tau_i)^2 \geq \sigma_{k+1}^2 + \sigma_{k+2}^2 + \dots + \sigma_n^2 = \|A - A_k\|_F^2$$

This completes the proof. □

IIT ROORKEE

NPTEL ONLINE
CERTIFICATION COURSE
8

So, let us consider the proof here. So, first thing is that the rank of A_k is k and this is quite easy because if you look at the rank of A_k is rank of US_kV^T . Now, U and V are orthogonal matrices and hence of full rank. So, rank of A_k is nothing, but rank of S_k and rank of S_k is nothing, but lead nonzero values in the diagonal in the diagonal of S_k which is k . So, it means the rank of A_k is nothing, but the k . So, it is obvious that A_k has rank k .

Now, we want to show that if we take any B which is a m cross n matrix of rank k then we want to show that the Frobenius norm of A minus B square is greater than or equal to Frobenius norm of A minus A_k

So, let us take B and any m cross n matrix of rank k then the singular values of B , let us say $\tau_1, \tau_2, \dots, \tau_k$ and we assume that rest are all τ_{k+1} to τ_n are all 0 singular values. So, up to τ_1 to τ_k we have positive singular values and rest are 0 singular values.

Then we already know that the result we have shown in the first as this result if you look at this result that, let A and B be two real m cross n matrix then we know that the Frobenius norm of B minus a is bigger than this. So, using this result we can say that that Frobenius norm of A minus B whole square is bigger than $\sum_{i=1}^n (\sigma_i - \tau_i)^2$, and if you look at this is what this is greater than or equal to $\sum_{i=1}^k \sigma_i^2 + \sum_{i=k+1}^n \sigma_i^2$ and so on σ_n^2 .

Now, if you look at this is nothing, but the Frobenius norm of A minus A_k square. So, it means that that if it calculate the Frobenius norm of A minus B square then it is greater than or equal to Frobenius norm of A minus A_k square and the equality follows if you replace B as A_k . So, this complete the proof of the theorem that Eckart young theorem that if you define A_k like $U_k V^T$ then minimum of Frobenius norm of A minus B , where B rank of B is a matrix of rank A , then minimum of rank B equal to k Frobenius norm of A minus B is equal to Frobenius norm of A minus A_k .

(Refer Slide Time: 14:01)

Example

Let

$$A = \begin{pmatrix} 1 & 2 \\ 2 & 3 \\ 3 & 4 \end{pmatrix}, \quad \sigma_1 = 6.5468, \quad \sigma_2 = 0.3742$$

Let k be 1. Then

$$A_1 = US_1V^T = \begin{pmatrix} 1.2608 & 1.8193 \\ 2.0534 & 2.9630 \\ 2.8460 & 4.1067 \end{pmatrix}$$

Out of all the matrices of rank 1, A_1 is closest to A .

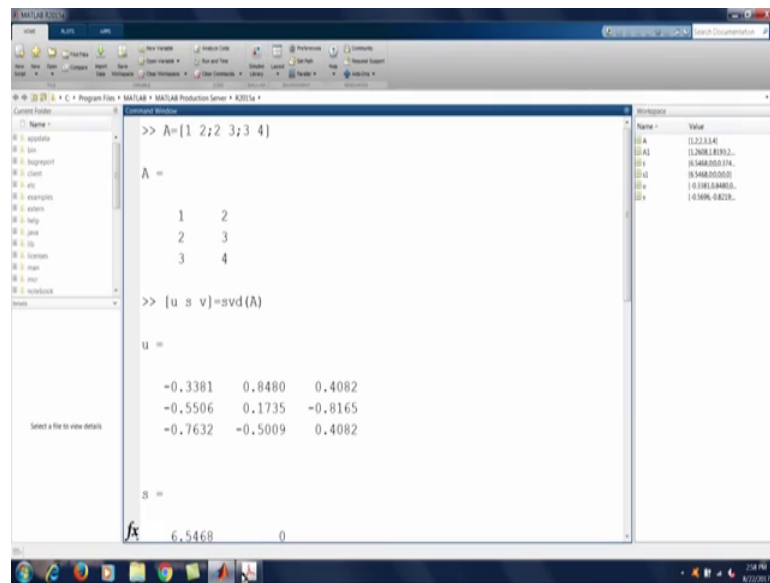

FT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 9

Now, consider the similar proof in 2 norm, but before that let us consider the following example here we have matrix A given as a 1 2, 2 3, 3 4 and we can easily calculate the singular values of this matrix A as σ_1 is equal to 6.5468 and σ_2 as 0.3742. And we want to find out a matrix B which is of rank 1 and it is closest to the matrix A .

So, for that you define A_1 as US_1V^T , where S_1 is a diagonal matrix where the diagonal entry is σ_1 and rest all 0. Then we can calculate that A_1 as US_1V^T and it is given by this. So, by previous theorem we can show that this A_1 is the matrix of rank 1 and it is closest to the matrix A and this you can verify with the help of your MATLAB. So, you can see whether it is true or not.

So, we want to show the verification of this example using MATLAB.

(Refer Slide Time: 15:20)

A screenshot of the MATLAB R2013a interface. The Command Window shows the following code and output:

```
>> A=[1 2; 2 3; 3 4]
A =
     1     2
     2     3
     3     4

>> [u s v]=svd(A)
u =
 -0.3381    0.8480    0.4082
 -0.5506    0.1735   -0.8165
 -0.7632   -0.5009    0.4082

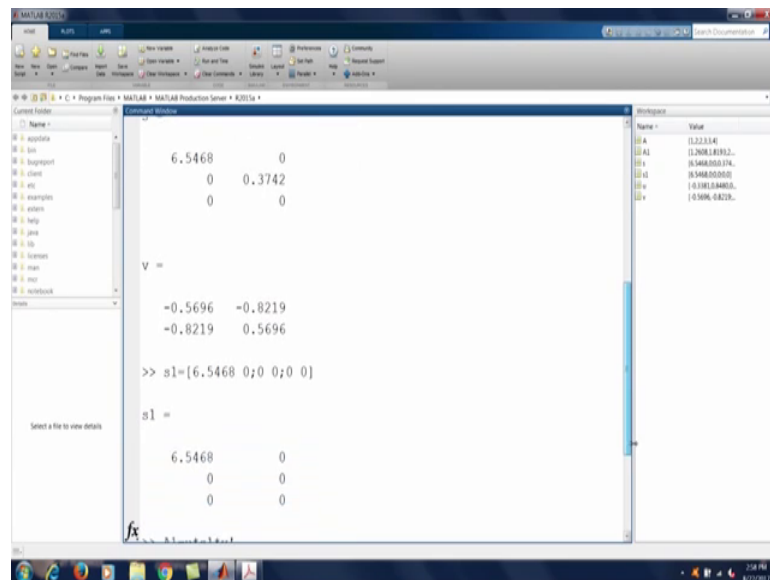

s =
 6.5468     0
```

The Workspace window on the right shows the following variables:

Name	Value
A	(2,2) double
A1	(1,200) 1x192...
s	(5,548) 0.0374...
u	(3,101) 0.4083...
v	(3,509) 0.8219...

So, if you look at we define our matrix A as 1 2, 2 3, 3 4. If you display it and then A is given as 1 2, 2 3, 3 4 and then we try to find out say singular value decomposition of this matrix. So, it means that U is an orthogonal matrix given as this and S is this and V as this and this is given here.

(Refer Slide Time: 15:40)

A screenshot of the MATLAB R2013a interface. The Command Window shows the following code and output:

```
6.5468     0
         0    0.3742
         0         0

V =
 -0.5696   -0.8219
 -0.8219    0.5696

>> s1=[6.5468 0; 0; 0]
s1 =
 6.5468     0
         0     0
         0     0
```

The Workspace window on the right shows the following variables:

Name	Value
A	(2,2) double
A1	(1,200) 1x192...
s	(5,548) 0.0374...
u	(3,101) 0.4083...
v	(3,509) 0.8219...

This here we have simply noted down sigma 1 and sigma 2 as 6.5468 and 0.3742 and which is given here say 6.5468 and 0.3742.

So, here if we define a matrix S_1 where S_1 will consist only first singular values the bigger singular value 6.5468 and rest entries are 0. So, it means that S_1 is your matrix like this $\begin{bmatrix} 6.5468 & 0 \\ 0 & 0 \end{bmatrix}$ and then we calculate A_1 as US_1V^T then your matrix A_1 is given as $\begin{bmatrix} 1.2608 & 1.8193 \\ 2.0534 & 2.9630 \\ 2.8460 & 4.1068 \end{bmatrix}$ and so on.

(Refer Slide Time: 16:15)

```

-0.5696 -0.8219
-0.8219 0.5696

>> s1=[6.5468 0; 0 0]

s1 =

    6.5468    0
         0    0
         0    0

>> A1=u*s1*v'

A1 =

    1.2608    1.8193
    2.0534    2.9630
    2.8460    4.1068

fx>> A1=u*s1*v'
  
```

And we can say that this matrix A_1 which is listed here is a matrix of a rank 1 and A_1 is closest to A , that you can check that rank of A_1 is what.

(Refer Slide Time: 16:43)

```

    6.5468    0
         0    0
         0    0

>> A1=u*s1*v'

A1 =

    1.2608    1.8193
    2.0534    2.9630
    2.8460    4.1068

>> rank(A1)

ans =

     1

fx>>
  
```

we have $\sigma_{k+1}, \sigma_{k+2}, \dots, \sigma_r$ and rest all 0. So, the remaining $r - k$ entries are nonzero and rest are all 0.

Now, we already know that the 2 norm of a matrix P is $\sigma_{\max}(P)$ singular here σ_{\max} represent the singular maximum singular values of matrix P , then 2 norm of P is the maximum singular value of P then we want to find out say 2 norm of this matrix $A - A^k$. So, 2 norm of $A - A^k$ is the $\sigma_{\max}(A - A^k)$, and if you look at $\sigma_{\max}(A - A^k)$ is nothing but σ_{k+1} , as we have already arranged our single values in this fashion that $\sigma_1 \geq \sigma_2 \geq \dots$. So, σ_{k+1} , so among these singular values your σ_{k+1} is the maximum singular value of this matrix $A - A^k$. So, what we have proved here is that the 2 norm of $A - A^k$ is σ_{k+1} .

Now, what remains is to prove that two norms of 2 norm of $A - B$ is bigger than this quantity. So, let B be any $m \times n$ matrix of rank k , we will prove that square of 2 norm of $A - B$ is greater than or equal to 2 norm of $A - A^k$ whole square and that is nothing, but σ_{k+1}^2 .

(Refer Slide Time: 20:19)

By the Rank- Nullity Theorem, it follows that

$$\text{rank}(B) + \text{nullity}(B) = n = \text{number of columns of } B$$

Hence,

$$\text{nullity}(B) = n - k$$

Therefore, we can find orthonormal vectors x_1, x_2, \dots, x_{n-k} so that

$$\mathcal{N}(B) = \text{span}\{x_1, x_2, \dots, x_{n-k}\}$$

Consider also the subspace W spanned by the first $k + 1$ right singular vectors of A ; i.e.,

$$W = \text{span}\{v_1, v_2, \dots, v_{k+1}\}$$

Since the right singular vectors of A are orthonormal, it is obvious that

$$\dim(W) = k + 1$$

If W_1 and W_2 are two subspaces of \mathbb{R}^n , then we know that

$$\dim(W_1 + W_2) = \dim(W_1) + \dim(W_2) - \dim(W_1 \cap W_2)$$

NPTEL ONLINE CERTIFICATION COURSE

12

For that let us assume that for this rank of B which is already known as $r = k$. Then by the rank nullity theorem we can say that nullity of B is $n - k$, here rank of B plus nullity of B is equal to n , where n is the number of columns of B and since rank of B is your k then nullity of B can be written as $n - k$. So, if nullity of B is $n - k$ then

we can always find out orthonormal vectors x_1 to x_{n-k} so that a nullity null space of B can be spanned by these $n-k$ orthonormal vectors.

Now, also consider a subspace W which is spanned by the first $k+1$ right singular vectors of A . It means at the first $k+1$ columns of matrix V . So, let us say that W is span of v_1 to v_{k+1} , and we already know that by construction the right singular vectors of A are orthonormal. So, we can say that this rank dimension of this W is going to be $k+1$.

Now, look at the dimension of $W + N(B)$. So, we already know that if W_1 and W_2 are two subspaces of \mathbb{R}^n then dimension of $W_1 + W_2$ you can find out using this formula, that is dimension of W_1 plus dimension of W_2 minus dimension of $W_1 \cap W_2$. So, this we have already seen.

(Refer Slide Time: 22:01)

Taking $W_1 = \mathcal{N}(B)$ and $W_2 = W$, we find that

$$n \geq \dim(\mathcal{N}(B) + W) = (n - k) + (k + 1) - \dim(\mathcal{N}(B) \cap W)$$

Therefore,

$$\dim(\mathcal{N}(B) \cap W) \geq 1$$

Thus, we can find a vector $x \in \mathcal{N}(B) \cap W$ such that $\|x\|_2 \neq 0$. Define

$$z = \frac{x}{\|x\|_2}$$

Then $z \in \mathcal{N}(B) \cap W$ and $\|z\|_2 = 1$.
 Since $z \in \mathcal{N}(B)$, we have $Bz = 0$. Since $z \in W$, we can express z as

$$z = \alpha_1 v_1 + \alpha_2 v_2 + \dots + \alpha_{k+1} v_{k+1}$$

Therefore,

$$(A - B)z = Az = \sum_{i=1}^{k+1} \sigma_i \alpha_i u_i$$

And we, so if we take W_1 as a null space of B and W_2 as W then we can say that your dimension of $N(B) + W$ it cannot exceed n . So, n greater than or equal to dimension of $N(B) + W$ is equal to $n - k$ which is the dimension of null space of B plus a dimension of W minus dimension of null space of B intersection W .

So, if you look at this is going to be $n + 1$ and it can since this $n + 1$ minus dimension of $N(B) \cap W$ cannot exceed this n . So, this implies that the dimension of null space of B intersection W has to be greater than or equal to 1. It

means that they exist a non0 vector in this at least one nonzero vector in this in this intersection. So, it means that we can always find out a vector x belonging to null space of B intersection W such that the it is nonzero or you can say in particular to norm of this vector x is nonzero.

Now, with the help of this x we define a vector z as x by 2 norm of x so that the 2 norm of z is equal to 1. So, it means that z belongs to null space of B intersection W and 2 norm of z is 1. Now, with this z we already know that z belongs to null space of B it means that Bz is going to be 0, and since z also belongs to W it means that z can be expressed as linear combination of v 1 to v k plus 1. So, we can say that z is equal to alpha 1 v 1 plus alpha 2 v 2 and so on alpha k plus 1, v k plus 1 therefore, if we calculate a minus B z then it is basically Az only because Bz is going to be 0. Now, Az is basically what? a operating on this.

Now, we know that alpha 1 a v 1. Now, a v 1 is basically sigma 1 u 1 and a v 2 is sigma 2 u 2 and so on then we can write that A minus B is z is nothing but i equal to 1 to k plus 1 sigma i alpha i u i.

(Refer Slide Time: 24:25)

Since $Av_i = \sigma_i u_i$, where u_i is the corresponding left singular vector of A, for $i = 1, 2, \dots, k + 1$.

Since u_1, u_2, \dots, u_{k+1} are also orthonormal vectors and $\|z\|_2 = 1$, it follows that

$$\|(A - B)z\|_2^2 = \sum_{i=1}^{k+1} \sigma_i^2 \alpha_i^2 \geq \sigma_{k+1}^2 \sum_{i=1}^{k+1} \alpha_i^2 = \sigma_{k+1}^2 \|z\|_2^2 = \sigma_{k+1}^2$$

Hence,

$$\|A - B\|_2 \geq \frac{\|(A - B)z\|_2}{\|z\|_2} \geq \sigma_{k+1}$$

This completes the proof.

14

And we this is follows because Av i equal to sigma i u i, where u i is the corresponding left singular vectors of a for i equal to 1 to k plus 1.

Now, we already know that this u_1 to u_{k+1} which are left singular vectors of A or orthonormal vectors and we also that $\|z\|_2$ is equal to 1 and hence we can say that $\|A - B\|_2^2$ is greater than equal to σ_{k+1}^2 . Now, if you divide by $\|z\|_2^2$ then you can say that $\|A - B\|_2$ is greater than equal to σ_{k+1} and it is greater than or equal to σ_{k+1} .

So, if we take any matrix B of rank k then $\|A - B\|_2$ is greater than equal to σ_{k+1} . Also we have seen that that if we take B as A_k then $\|A - B\|_2$ is exactly σ_{k+1} . So, if we combine these two facts then we can say that the minimum of this $\|A - B\|_2$, where we are taking minimum over all the matrix B of rank k then it is nothing, but $\|A - A_k\|_2$ and it is equal to σ_{k+1} and this complete the proof of this theorem.

(Refer Slide Time: 26:04)

Corollary

Let $A = USV^T$ be a SVD of a real $m \times n$ matrix A , where $m \geq n$. Let the rank of A be r . Let

$$\sigma_1 \geq \sigma_2 \geq \dots \geq \sigma_r > 0$$

be the positive singular values of A . If B is any $m \times n$ matrix such that

$$\|A - B\|_2 < \sigma_r,$$

then

$$\text{rank}(B) \geq r$$

IIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 15

So, now, let us consider a important corollary based on the previous theorem and it says that let A is given as USV transpose B a singular value decomposition of a real m cross n matrix A , where m is greater than equal to n and let the rank of A be r and we arrange the singular values as this. And these are all positive singular values of A , and if B is any m cross n matrix such that $\|A - B\|_2$ is less than σ_r then the rank of B is going to be greater than or equal to r .

So, let us see what it how we can prove this corollary and then we try to see what the geometric interpretation of this corollary.

(Refer Slide Time: 26:48)

Proof.
 We prove this result by contradiction. Assume, if possible that

$$k = \text{rank}(B) < r$$

As we know that A_k is closest to A among all rank - k matrices in 2 - norm and

$$\|A - A_k\|_2 = \sigma_{k+1}$$

Therefore,

$$\|A - B\|_2 \geq \|A - A_k\|_2 = \sigma_{k+1}$$

Hence,

$$\|A - B\|_2 \geq \sigma_{k+1} \geq \sigma_r$$

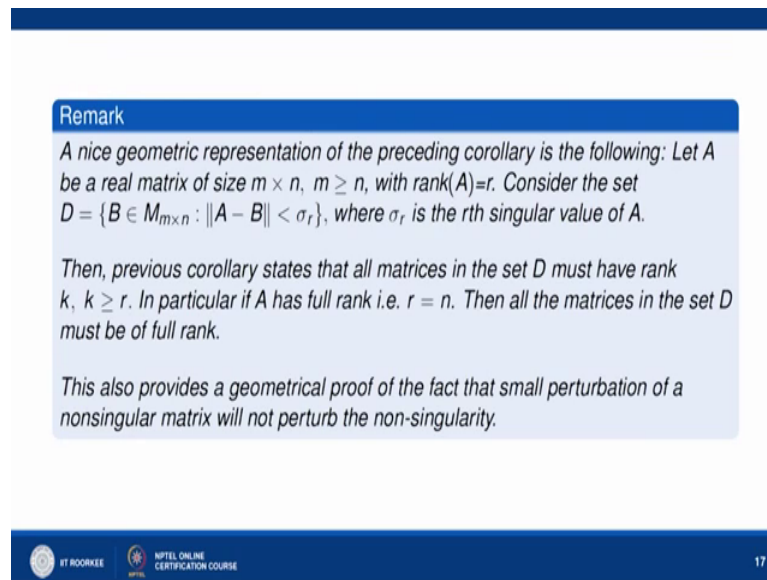

(Note that $k < r \Rightarrow \sigma_{k+1} \geq \sigma_r$).
 This contradicts the hypothesis that $\|A - B\|_2 < \sigma_r$, and the proof follows. \square

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 16

So, proof is quite simple. So, we prove this result by contradiction. So, assume it possible that rank of B is less than r. What we want to wanted to prove is that rank of B is greater than equal to r. So, let us assume that rank of B is less than r and let us say that it is k and we already know that this A k is the closest to a among all rank k matrices in 2 norm. So, that we have just proved in previous theorem and we say that 2 norm of A minus A k is sigma k plus 1. So, we, so it means that 2 norm of A minus B is greater than equal to 2 norm of A minus A k which is nothing, but sigma k plus 1 that is precisely the theorem we have just proved. And hence 2 norm of A minus B is greater than equal to sigma k plus 1.

And since your k is less than r then sigma k plus 1 is bigger than sigma r, but this contradict the hypothesis that 2 norm of A minus B is less than sigma r. So, this complete the proof of this simple corollary. So, what we have shown here that if we assume the rank of B is less than r then 2 norm of A minus B is greater than equal to sigma, but we have already assumed that 2 norm of A minus B is less than sigma r. So, we get the contribution.

Remark

A nice geometric representation of the preceding corollary is the following: Let A be a real matrix of size $m \times n$, $m \geq n$, with $\text{rank}(A)=r$. Consider the set $D = \{B \in M_{m \times n} : \|A - B\| < \sigma_r\}$, where σ_r is the r th singular value of A .

Then, previous corollary states that all matrices in the set D must have rank k , $k \geq r$. In particular if A has full rank i.e. $r = n$. Then all the matrices in the set D must be of full rank.

This also provides a geometrical proof of the fact that small perturbation of a nonsingular matrix will not perturb the non-singularity.

FT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 17

So, we can understand the by the following remark that what is the meaning of the previous corollary. So, we can say that a nice geometric representation of the preceding corollary is the following that let A be a real matrix of size m cross n where m is greater than or equal to n with rank of A is r . Then we can consider this set S it is a set of all matrices of size m cross n such that 2 norm of A minus B is less than σ_r , where σ_r is the r th singular values of A .

Then the previous corollary states that all matrices in this set D must have rank k where k is greater than equal to r or you can say that any matrix in this set must have rank greater than or equal to r , or in particular if we assume that rank of A has full it means that r is equal to n then we can say that any matrix in this set D must have full rank. And it also provide a geometric proof of the fact that small perturbation of a nonsingular matrix will not perturb the non singularity. So, it means that if we perturb a nonsingular matrix by a little then it will not perturb the non singularity status of the matrix A .

So, we will this we stop our lecture. So, in this lecture what we have seen here is that singular value decomposition not only give the the best way we can say to find out the matrix rank of the matrix A , but also it also gives the approximation of the matrix A by A_k , where A_k approximate our matrix A in 2 norm and F norm and it is known as the best approximation of the rank k .

So, in next lecture we continue our study and we will see some more important result obtained through singular value decomposition.

Thank you.
