**Lecture – 53**  
**Householder QR factorization – I**

Hello friends, welcome to this lecture, in this lecture we will discuss the concept of householder QR factorization and this can be considered as An important application of householder matrices, and this householder QR factorization has many applications in for example, least square theory in both the over determined case and underdetermined case and in Eigen values problem and in computing the singular value of a matrix. So, here in this lecture, we will discuss what is a householder QR factorization and how given a matrix we find out the QR decomposition of the matrix.

(Refer Slide Time: 01:16)

Householder QR Factorization Theorem

**Theorem 1**

*If  $A$  is any real  $n \times n$  matrix, then there exist an orthogonal matrix  $Q$  and an upper triangular matrix  $R$  such that*

$$A = QR$$

*where the matrix  $Q$  can be expressed as a product of Householder matrices.*

IT ROORKEE    NPTEL ONLINE CERTIFICATION COURSE    2

So, let us start with the lecture. So, the theorem says that if  $A$  is any  $n$  cross  $n$  matrix which is real then they exist An orthogonal matrix  $Q$  and An upper triangular matrix  $R$  such that  $A$  equal to  $Q$  into  $R$  where the matrix  $Q$  can be expressed as a product of householder matrices.

So, here we try to find out this QR factorization of  $A$  with the help of householder matrices. So, basically the proof of this theorem is basically a constructive proof.

(Refer Slide Time: 01:43)

**Proof.** This proof is a constructive proof and consist of  $(n - 1)$  steps.  
**Step 1:** Find a Householder matrix  $H_1$  such that the matrix

$$A_1 = H_1 A$$

has zeros below the first diagonal entry in its first column, i.e.  $A_1$  has the form

$$A_1 = H_1 A = \begin{bmatrix} * & * & \cdots & * \\ 0 & * & \cdots & * \\ \vdots & \vdots & \ddots & \vdots \\ 0 & * & \cdots & * \end{bmatrix}$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 3

And it consists of  $n$  minus 1 step, where  $n$  represent the size of the matrix  $A$ . So, we have to do this  $n$  minus 1 steps. So, the idea is that given a matrix, we want to find out matrices such that if you multiply that then it will become An upper triangular matrix.

So, first it has  $n$  minus 1 step. So, a step one is find a householder matrix  $H_1$  such that the matrix  $A_1$  equal to  $H_1 A$  has the following form, it means that has 0s in the first column just before just below the first diagonal entry. So,  $H_1$  has a fact that only the first diagonal entry is nonzero, rest are all 0 in first column. Similarly, what we try to do this in first steps, second step what we try to do we repeat the same process, it means that in second column, all the entries below the diagonals are 0s and so on we can go up to  $n$  minus 1 terms.

So, how to find out these householder matrices which gives the required form that we are going to discuss in this theorem. So, first let us find this  $H_1 A$ . So,  $A_1$  equal to  $H_1 A$  where  $A_1$  has this form and  $H_1$  we need to find out.

(Refer Slide Time: 03:07).

To get the above form we proceed as follows: Find a Householder matrix

$$H_1 = I - 2w_1 w_1^T, \text{ where } \|w_1\|_2 = 1$$

such that

$$H_1 \begin{bmatrix} a_{11} \\ a_{21} \\ \vdots \\ a_{n1} \end{bmatrix} = \begin{bmatrix} * \\ 0 \\ \vdots \\ 0 \end{bmatrix}$$

Then the product  $A_1 = H_1 A$  will have zeros below the first diagonal entry in its first column. Now, we start working with  $A_1 = H_1 A$  in place of  $A$ , i.e.  $A \leftarrow A_1$ . We can write  $A_1$  as

$$A_1 = \begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1n} \\ 0 & a_{22} & \cdots & a_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ 0 & a_{n2} & \cdots & a_{nn} \end{bmatrix}$$

 IIT ROORKEE  NPTEL ONLINE CERTIFICATION COURSE 4

So, to get the above form, we proceed as follows. So, find a householder matrix  $H_1$  as  $I$  minus  $2\omega_1\omega_1^T$ , where  $\omega_1$  is a unit vector. So, the effect of  $H_1$  is what that if we apply it on the first column of  $A$  that is  $a_{11}$  to  $a_{n1}$  then the image of this vector under  $H_1$  is going to be first non zero entries and rest all 0s entry. Then, the product  $A_1 = H_1 A$  will have 0 below the first diagonal entry in its first column.

Once we have this  $H_1$  then we start working with  $A_1$  in place of  $A$ . So, now, without loss of generality, we can write  $A_1$  as in this follows though this when we apply this  $H_1$  on this  $A$  of course, this first entry will also be changed, but now we say that suppose we representing the first entry by  $a_{11}$  only and then we try to find out  $H_2$  such that if we apply  $H_2$  on this  $A_1$ , then all the entries below this second column, all the entries below the diagonal term is going to be 0.

(Refer Slide Time: 04:26)

**Step 2:** Find a Householder matrix  $H_2$  such that the matrix

$$A_2 = H_2 A_1 = (H_2 H_1) A$$

has zeros below the first and second diagonal entries in its first two columns, i.e.  $A_2$  has the form

$$A_2 = H_2 H_1 = \begin{bmatrix} * & * & * & \cdots & * \\ 0 & * & * & \cdots & * \\ 0 & 0 & * & \cdots & * \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & * & \cdots & * \end{bmatrix} \quad (1)$$

For this we proceed as follows: Find a Householder matrix

$$\hat{H}_2 = I_{n-1} - 2\hat{w}_2 \hat{w}_2^T, \text{ where } \|\hat{w}_2\|_2 = 1$$

\*

FT ROORKEE

NPTEL ONLINE  
CERTIFICATION COURSE

5

So, it means that in step two find a householder matrix  $H_2$  such the matrix  $A_2$  equal to  $H_2$  into  $A_1$ , where  $A_1$  is nothing, but  $H_1 A$ , so,  $A_2$  is basically  $H_2$  into  $H_1$  into  $A$ . Has 0 below the first and second diagonal entries in it in its first two columns, that is in first column this is diagonal term and rest all these terms are 0. In second column, this is the diagonal entry and rest are all 0s, so that we need to find out. So, once we have  $H_2$  then we can write  $A_2$  as  $H_2$  into  $H_1$  of  $A$ . For this, we proceed as follows, find a householder matrix which is defined as  $H_2$  hat and it is given by  $I_{n-1}$  minus 2 omega 2 hat into omega 2 hat transpose, where omega 2 is An unit vector in  $\mathbb{R}^{n-1}$  having the 1.

(Refer Slide Time: 05:24)

such that

$$\hat{H}_2 \begin{bmatrix} a_{22} \\ a_{32} \\ \vdots \\ a_{n2} \end{bmatrix} = \begin{bmatrix} * \\ 0 \\ \vdots \\ 0 \end{bmatrix}$$

Next, we define  $H_2$  by

$$H_2 = \begin{bmatrix} I_1 & 0 \\ 0 & \hat{H}_2 \end{bmatrix}.$$

and

$$w_2 = \begin{bmatrix} 0 \\ \hat{w}_2 \end{bmatrix} \in \mathbb{R}^n.$$

Observe that

$$\|w_2\|_2 = \|\hat{w}_2\|_2 = 1$$

FT ROORKEE

NPTEL ONLINE  
CERTIFICATION COURSE

6

And such that the  $H_2$  hat if we apply on  $a_{22}$  to  $A_{N2}$  then it will give you in place of  $a_{22}$  it is some non zero quantity and all the other entries are simply 0. And once we have this  $H_2$  tilde  $H_2$  hat then we can define  $H_2$  by  $H_2$  as  $I_1 \ 0 \ 0 \ H_2$  hat where this representation is a block diagonal representation. Here this is a 0 matrix and this is also a 0 matrix of appropriate size.  $I_1$  is identity matrix of size 1 cross 1 and  $H_2$  tilde  $H_2$  hat is a matrix of  $n$  minus 1 cross  $n$  minus 1 size and once we have  $H_2$  here we can define  $w_2$  as  $0 \ w_2$  hat. Now by defining this  $w_2$  as this, we know the norm of  $w_2$  is nothing, but norm of  $w_2$  hat and it is given as 1.

(Refer Slide Time: 06:27)

and

$$I - 2w_2w_2^T = \begin{bmatrix} I_1 & 0 \\ 0 & I_{n-1} - 2\hat{w}_2\hat{w}_2^T \end{bmatrix} = \begin{bmatrix} I_1 & 0 \\ 0 & \hat{H}_2 \end{bmatrix} = H_2$$

**Step i:** In this step we find a Householder matrix  $H_i$  such that

$$A_i = H_i A_{i-1} = \dots = (H_i H_{i-1} \dots H_2 H_1) A$$

has zeros below the first  $i$  diagonal entries in its first  $i$  columns.

$$\hat{H}_i = I_{n-(i-1)} - 2\hat{w}_i\hat{w}_i^T, \text{ where } \|\hat{w}_i\|_2 = 1$$

$$\hat{H}_i \begin{bmatrix} a_{ii} \\ a_{i+1,i} \\ \vdots \\ a_{ni} \end{bmatrix} = \begin{bmatrix} * \\ 0 \\ \vdots \\ 0 \end{bmatrix}, H_i = \begin{bmatrix} I_{i-1} & 0 \\ 0 & \hat{H}_i \end{bmatrix}, \text{ and } w_i = \begin{bmatrix} 0 \\ \hat{w}_i \end{bmatrix}.$$

So, you can define  $H_2$  as  $I$  minus  $2 \omega_2 \omega_2^T$  and if you calculate it is given as  $I_1 \ 0 \ 0$  and here it is  $I_{n-1}$  minus  $2 \omega_2 \omega_2^T$  hat  $\omega_2$  hat transpose and this we are defining this is nothing, but  $H_2$  hat, so, your  $H_2$  is given as  $I_1 \ 0 \ 0 \ H_2$  hat and this we are defining as  $H_2$ .. So, that is what we are writing here.

(Refer Slide Time: 06:59)

Handwritten mathematical derivations for Householder's QR algorithm:

- Matrix  $A = \begin{bmatrix} a_{11} & a_{12} & a_{13} & \dots & a_{1n} \\ a_{21} & a_{22} & a_{23} & \dots & a_{2n} \\ a_{31} & a_{32} & a_{33} & \dots & a_{3n} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ a_{n1} & a_{n2} & a_{n3} & \dots & a_{nn} \end{bmatrix}$
- First Householder vector:  $w_1 = \frac{x_1 - \gamma_1 e_1}{\|x_1 - \gamma_1 e_1\|}$ , where  $\gamma_1 = -\text{sign}(a_{11}) e_1$
- Householder matrix:  $H_1 = I - 2w_1 w_1^T$
- Resulting matrix:  $A_1 = H_1 A = \begin{bmatrix} x & x & \dots & x \\ 0 & x & \dots & x \\ 0 & x & \dots & x \\ \vdots & \vdots & \ddots & \vdots \\ 0 & x & \dots & x \end{bmatrix}$
- Second Householder vector:  $w_2 = \frac{x_2 - \gamma_2 e_2}{\|x_2 - \gamma_2 e_2\|}$
- Second Householder matrix:  $H_2 = I - 2w_2 w_2^T$
- Final QR decomposition:  $A = QR$ , where  $Q = H_1 H_2 \dots$  and  $R = A_1$

So, idea is this that we started with this matrix A which is a square matrix of size n cross n and what we try to do here we want to find out we want to write this A as Q into R, where R is the upper triangular matrix and Q is the orthogonal matrix which we are going to find out.

So, basically we are try to reduce this in upper triangular matrix. So, upper triangular matrix means we want to find out that Q such that all these entries below diagonal entries are simply vanish. So, that we are saying that this Q can be considered as product of householder matrices. So, this we are doing in the following steps.

So, in first step we find out a matrix H1 such that A1 is written as H1A and what is the form of A1, A1 has a form that in the first column below the first diagonal entries, all entries are 0 and how to find out this H1, this we already know that if you want to find out H1 having this property that it will convert this matrix into this matrix then we know that H1 is defined as I minus 2 omega 1 omega 1 transpose, where omega 1, is basically your this x you, if you call this vector say x.

Let us say call it x1 then we can find out x1 minus y1 and here x1 divided by norm of x1 minus y1 and y1 is what, y1 is the minus sign of x11 basically, the first entry that is a11. So, here I have to write a sign of a11 into e1. So, once we have y1 here then divided by norm of x1 upon norm of x1 minus y1. So, that we already know using algorithm you

can find out  $w_1$  and then we can find out  $H_1$  and once we have  $H_1$  then  $A_1$  has the following representation.

Now, once we have  $A_1$  then we forget about this for the time being and start working with this. We want to find out now another a householder matrix which will remain say same structure in a column 1, but in column 2 it will make all these entries as 0 entry before the second column, it means that the effect of  $H_2$  on this  $A_1$ ,  $A_1$  which is written as  $H_1 A$ , the effect of  $H_2$  in over this  $A_1$  is the following that in first column below the diagonal entries, it is all 0s and here in second column also the below the diagonal term all the entries are 0.

So, basically what we want that  $H_2$  in second column reduce these entries as 0s and it will have no effect on this first column. For that we define  $H_2$  as this, as  $H_2$  as  $I_1 \ 0 \ 0 \ \hat{H}_2$  hat which is of size  $N$  minus 1 cross  $N$  minus 1 where  $\hat{H}_2$  hat has this effect  $A_{22}, A_{32}, A_{N2}$  tending to cross 0 0 0 as on. So, it means what it is basically looking at these many vectors and keeping this as nonzero, rest all 0 entries. (Refer Time: 10:35)

So, here we define  $\hat{H}_2$  hat as  $I_{n-1} - \omega_2 \hat{\omega}_2^T$ . How to find out this  $\omega_2$  hat here the effect of  $\hat{H}_2$  hat is on this. So, this is your  $x$  and this is your  $y$ . So, based on  $x$  and  $y$  we can use algorithm to find out this  $\hat{H}_2$  hat. So, once we have  $\hat{H}_2$  hat then we can define our  $H_2$  as  $I_1 \ 0 \ 0 \ \hat{H}_2$  hat and  $w_2$  we can define as  $0 \ n_2 \ w_2$  hat and we can see that by defining such  $H_2$  and  $w_2$  the effect of this  $I - 2 \omega_2 \omega_2^T$  is basically  $I - 2$ , here  $\omega_2$  is this and  $\omega_2^T$  we can write it like that. And if you calculate, it is coming out to be that  $I_1 \ 0 \ 0 \ \hat{H}_2$  hat and which is nothing, but the proposed form of  $H_2$ .

So, it means that the form of  $H_2$  is given by  $I - 2 \omega_2 \omega_2^T$  where  $\omega_2$  is defined by  $0 \ 1 \ \hat{\omega}_2$ . So, in this way we can find out our matrix  $H_2$  such that if you apply this  $H_2$  on  $A_1$  then it has the following form and this we keep on doing for  $n - 1$  steps. So, for every step what we want that it will make the entries below the diagonal term as 0 and it will not touch any 0s which have already achieved.

So, in  $i$ th step, we can say that in step  $i$ , in this step we find a householder matrix  $H_i$  such that  $A_i$  can be written as  $H_i$  into  $A_{i-1}$  where  $A_{i-1}$  is  $H_{i-1}$  into  $H_{i-2}$  up to  $H_1 A$ . So, here  $A_i$  is written as the product of householder matrices into  $A$

and this has a property that it has 0s below the first  $i$  diagonal entries in its first  $i$  columns.

So, we can now find out this  $H_i$ ,  $H_i$  can be written as  $I - 2w_i w_i^T$ , where  $w_i$  basically is a unit vector. The effect of  $H_i$  on  $a_{ii}$  to  $a_{ni}$  is that at this place at the place of  $a_{ii}$  we have non zero entry and rest all these entries are your 0s entry and once we have  $H_i$  defined then we can define capital  $H$  as  $H = H_n H_{n-1} \dots H_2 H_1$  and  $w_i$  we can define as  $0 \dots w_i \dots$ .

(Refer Slide Time: 13:30)

$\|w_i\|_2 = \|\hat{w}_i\|_2 = 1$

$$I - 2w_i w_i^T = \begin{bmatrix} I_{i-1} & 0 \\ 0 & I_{n-(i-1)} - 2\hat{w}_i \hat{w}_i^T \end{bmatrix} = \begin{bmatrix} I_{i-1} & 0 \\ 0 & \hat{H}_i \end{bmatrix} = H_i$$

Thus,  $H_i$  is a Householder matrix, and  $H_i$  preserves the zeros already created in the first  $i - 1$  steps, and also the product  $A_i = H_i A_{i-1}$  has zeros below the diagonal entries in its  $i^{\text{th}}$  column. Store  $A_i$  over  $A$ , i.e.  $A \leftarrow A_i$

Observe that the matrix  $A_{n-1} = H_{n-1} A_{n-2}$  obtained at the end of step  $(n - 1)$  is an upper triangular matrix  $R$ :

$$R = A_{n-1} = H_{n-1} A_{n-2} = \dots = H_{n-1} H_{n-2} \dots H_2 H_1 A \quad (2)$$

IIT ROORKEE
 NPTEL ONLINE CERTIFICATION COURSE

Once we have this  $H_i$  we can repeat this process and we can calculate that  $I - 2w_i w_i^T$  and as we have done here the calculation we can show that it is coming out to be  $H_i$ . So, once we have  $w_i$  define as this,  $w_i$  define as  $0 \dots w_i \dots$  then your form of  $H_i$  is  $I - 2w_i w_i^T$  and we say that  $H_i$  is a householder matrix and  $H_i$  preserved the 0es already created in the first  $i - 1$  steps and also the product  $A_i = H_i A_{i-1}$  has 0s below the diagonal entries in its  $i^{\text{th}}$  column.

Then we start working with  $A_i$  rather than  $A$  and we can say that  $A_i$  is now stored as  $A$  and we start working with  $A$  and this process we repeat up to  $n - 1$  step and at the end of  $n - 1$  is step we have a  $n - 1$  which is written as  $H_{n-1} A_{n-2}$ . What is the form of  $A_{n-1}$ , here this  $A_{n-1}$  has say the first  $n$  columns, we have 0 entries below the diagonal entries and a last column we have full column, we do

not have any effect on the last column and we can say that that form is nothing, but the upper triangular matrix form.

So, here we denote this  $A_{n-1}$  as  $R$ , so  $R$  can be written as  $A_{n-1}$  where  $A_{n-1}$  is nothing, but  $H_{n-1} A_{n-2}$  and this can be repeated as and we can say that this  $R$  can be written as  $H_{n-1}, H_{n-2}, H_2 H_1$  and  $A$ . So,  $R$  can be written as product of householder matrices into  $A$ . Now we say that if you look at the product of these householder matrices.

(Refer Slide Time: 15:41)

Define  $Q$  by

$$Q = H_1 H_2 \cdots H_{n-1}$$

Since each Householder matrix  $H_i$  is symmetric, we have

$$Q^T = H_{n-1}^T H_{n-2}^T \cdots H_2^T H_1^T = H_{n-1} H_{n-2} \cdots H_2 H_1 \quad (3)$$

From (2) and (3), we have

$$R = Q^T A$$

or

$$A = QR$$

Since each Householder matrix  $H_i$  is orthogonal,  $Q$  is orthogonal. This completes the proof.

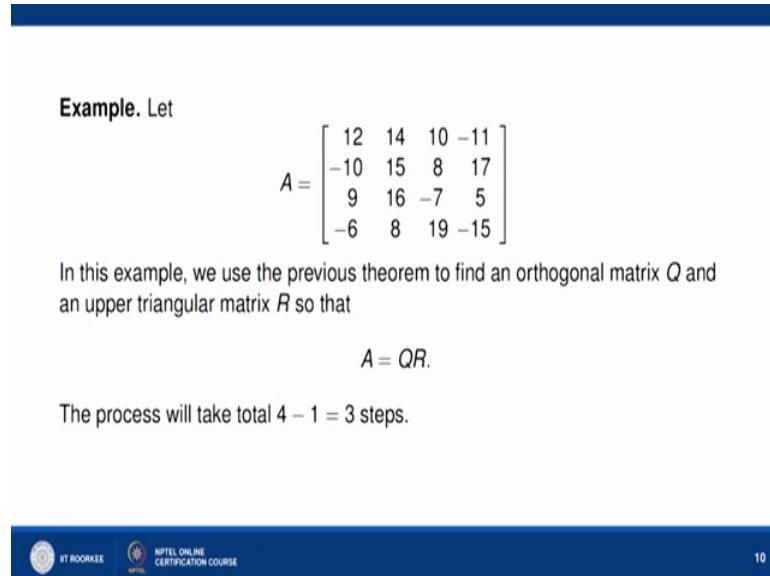

IIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 9

We define  $Q$  as  $H_1 H_2 \cdots H_{n-1}$  and since householder matrices are symmetric matrices, so it means that each  $H_1$  to  $H_{n-1}$  all are in symmetric matrices and so  $Q$  is also symmetric and you can find out  $Q$  transpose as a transpose of these matrices and we can write this as  $H_{n-1}^T H_{n-2}^T \cdots H_2^T H_1^T$ . So, using this  $Q$  transpose we can write  $R$  as  $Q^T A$  and since  $Q$  is also product of householder matrices and each householder matrices are orthogonal, so  $Q$  is also orthogonal matrices.

So,  $Q$  is basically both symmetric and orthogonal matrices. So, we can apply  $Q$  on both side and we can write  $A$  as  $Q$  into  $R$ , where this  $Q$  is orthogonal and  $R$  is an upper triangular matrices, so this is the proof of this theorem and this is not only the proof, this is basically the method to find out the QR decomposition. Using this proof, we try to find

out one example and we try to see that how we can find out this QR decomposition of a given matrix A.

(Refer Slide Time: 17:00)

**Example.** Let

$$A = \begin{bmatrix} 12 & 14 & 10 & -11 \\ -10 & 15 & 8 & 17 \\ 9 & 16 & -7 & 5 \\ -6 & 8 & 19 & -15 \end{bmatrix}$$

In this example, we use the previous theorem to find an orthogonal matrix  $Q$  and an upper triangular matrix  $R$  so that

$$A = QR.$$

The process will take total  $4 - 1 = 3$  steps.

ET ROORHKEE NPTEL ONLINE CERTIFICATION COURSE 10

So, let us consider this example, where A is given as 12, 14, 10, minus 11, minus 10, 15, 8, 17 and if you look at this is a 4 cross 4 matrix and we know that in the beginning of the proof of the theorem 1, we have seen that we need a N minus 1 step where N is the size of the matrix N. So, here size is a 4 cross 4 so we need a 4 minus 1 that is 3 steps. So, in 3 steps we are able to convert the matrix A into QR form, where Q is An orthogonal matrix and R is upper triangular matrix.

(Refer Slide Time: 17:42)

Step 1: Here, we find  $H_1$  so that

$$A_1 = H_1 A = \begin{bmatrix} * & * & * & * \\ 0 & * & * & * \\ 0 & * & * & * \\ 0 & * & * & * \end{bmatrix}$$

It is easy to see that  $H_1$  is defined by

$$H_1 = I_4 - 2w_1 w_1^T$$

where

$$w_1 = \begin{bmatrix} 0.9032 \\ -0.2914 \\ 0.2622 \\ -0.1748 \end{bmatrix}$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 11

So, first let us start with the first step. So, step one is that we need to find out  $H_1$ , so that  $A_1$  equal to  $H_1 A$  and what is the form of  $A_1$  that these entries are untouched, these entries may be anything, I really do not care, but in the first column below the diagonal entry that is this, we all have 0s. So, to find out this  $H_1$  we take this  $H_1$  as  $I_4$  minus 2 omega 1 omega 1 transpose where omega 1 is given by this. So, to find out this omega 1 we are using the algorithm let me show this using a (Refer Time: 18:20) how we can get this omega 1.

(Refer Slide Time: 18:28)

Therefore, we have

$$A_1 = H_1 A = \begin{bmatrix} -19.0000 & -6.0000 & 7.2105 & 8.7895 \\ 0.0000 & 21.4516 & 8.8998 & 10.6163 \\ 0.0000 & 10.1935 & -7.8098 & 10.7453 \\ 0.0000 & 11.8710 & 19.5399 & -18.8302 \end{bmatrix}$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 12

So, let us just see how we can get this A1 form here. So, we look at given A how to find out this H1 and before finding this H1 how to find out this omega 1 and such that A1 which is nothing, but H1 into A has the following form. So, let us first write down the matrix a here, so let me write the matrix A here, A is this 12, 14, 10, minus 11 that we have written down.

(Refer Slide Time: 18:54)

```

1- num=[10 10];
2- denom=[1 6 5 10];

>>
>>
>>
>>
>>
>> A=[12 14 10 -11;-10 15 8 17;9 16 -7 5;-6 8 19 -15]

A =

    12    14    10   -11
   -10    15     8    17
     9    16    -7     5
    -6     8    19   -15

fx>>

```

So, A is of this. So, it means that A I have written and then we try to find out the w1, so what is w1 here. So, to define w1, look at the first column here, 12, minus 10, 9, minus 6.

(Refer Slide Time: 19:19)

```

>> y1=[-1 0 0 0]';

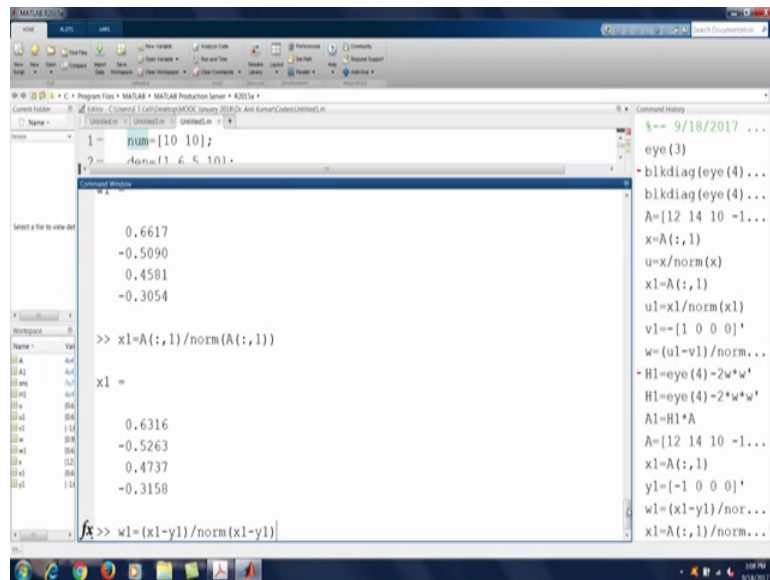

y1 =

    -1
     0
     0
     0

```

So, let us call this as a  $x_1$  here and we write  $x_1$  as the first column of the matrix  $A$  here. So,  $x_1$  is this and similarly we can define  $y_1$ . We are using the algorithm to find out  $H_1$ , so  $y_1$  is basically this minus sign of the first component of  $x_1$  that is 12, so 12 is positive sign. So, here we can define this as minus 1 0 0 0 and dash.

(Refer Slide Time: 19:58)

So,  $y_1$  is this here and then once we define this  $y_1$  then we can find out our  $w_1$ , let us say that  $w_1$  is given by say  $x_1$  minus  $y_1$  divided by norm of this. So, here we can define by norm of  $x_1$  minus 1 norm of  $x_1$  minus  $y_1$  and if you calculate this is your  $w_1$ . So, there is a small problem here that here our  $w_1$  will be this provided that  $x_1$  is the norm one, but here it is not, so, first we need to look at your  $x_1$  which is norm of this.

So, let me write it here  $x_1$  divided by, let me write it,  $x_1$  equal to this  $A$  comma 1 that will give you the vector  $x_1$  and divided by norm of this  $A$ , here we can find out 1 that will give you  $x_1$  and once we have  $x_1$  then we can define  $w_1$  like this. So, now you have  $w_1$  as 0.09032, minus 0.2914, 0.02622 and if you look at this is our  $w_1$ . So,  $w_1$  is 0.9032, minus 0.2914, and so on. So, it means that once we have  $w_1$  defined to us then we can define our  $H_1$ .

(Refer Slide Time: 21:51)

The screenshot shows a MATLAB window with the following code and output:

```

1 = [10 10];
2 = [1 6 5 10];

-0.6316  0.5263  -0.4737  0.3158
 0.5263  0.8302  0.1528  -0.1019
 -0.4737  0.1528  0.8625  0.0917
 0.3158  -0.1019  0.0917  0.9389

>> A1=H1*A

A1 =

-19.0000  -6.0000   7.2105   8.7895
 -0.0000  21.4516   8.8998  10.6163
  0.0000  10.1935  -7.8098  10.7453
 -0.0000  11.8710  19.5399 -18.8302
 1
  
```

The Command History window on the right shows the following sequence of commands:

```

blkdiag(eye(4)...
A=[12 14 10 -1...
x=A(:,1)
u=x/norm(x)
x1=A(:,1)
u1=x1/norm(x1)
v1=-[1 0 0 0]'
w=(u1-v1)/norm...
H1=eye(4)-2*w*w'
H1=eye(4)-2*w*w'
A1=H1*A
A=[12 14 10 -1...
x1=A(:,1)
y1=-[1 0 0 0]'
w1=(x1-y1)/nor...
x1=A(:,1)/norm...
w1=(x1-y1)/nor...
H1=eye(4)-2*w1...
A1=H1*A
  
```

So, to define H1, let us say H1 is basically what H1 is equal to this identity matrix of size 4 cross 4 minus 2 omega 1 into omega 1 transpose. So, let me write it here omega 1 transpose and it is coming out to be this H1 of this form. So, once we have H1 then we can define our A1 as H1 multiplied by A and it is of this form. So, A1 will be minus 19 and if you look at in the first column entries below the first diagonal entries, this diagonal entries are all 0, rest are um it may be any arbitrary thing, it is basically the before one. So, A1 is of this form. So, A1 is that all these entries in the first column below the diagonal entry we have 0s, rest may be anything. So, for that we have first find out W1 with the help of algorithm and once we have w1 then we can define H1. So, now we have this A1.

(Refer Slide Time: 23:05)

Step 2: Now, we find  $H_2$  so that  $A_2 = H_2 A_1$  has the form

$$A_2 = H_2 A_1 = H_2 \begin{bmatrix} -19.0000 & -6.0000 & 7.2105 & 8.7895 \\ 0.0000 & 21.4516 & 8.8998 & 10.6163 \\ 0.0000 & 10.1935 & -7.8098 & 10.7453 \\ 0.0000 & 11.8710 & 19.5399 & -18.8302 \end{bmatrix} = \begin{bmatrix} * & * & * & * \\ 0 & * & * & * \\ 0 & * & * & * \\ 0 & * & * & * \end{bmatrix}$$

First, we find  $\hat{H}_2$  so that

$$\hat{H}_2 \begin{bmatrix} 21.4516 \\ 10.1935 \\ 11.8710 \end{bmatrix} = \begin{bmatrix} * \\ 0 \\ 0 \end{bmatrix}$$

Observe that

$$\hat{H}_2 = I_3 - 2\hat{w}_2 \hat{w}_2^T$$

where

$$\hat{w}_2 = \begin{bmatrix} 0.9508 \\ 0.2019 \\ 0.2351 \end{bmatrix}$$

13

Now we start with this  $A_1$  and try to find out  $H_2$  such that this  $A_2$  will be the form that the entries in the second column below, the diagonal term is all 0s. So, now, we will find  $H_2$ , so that  $A_2 = H_2 A_1$  has the form  $A_2$  as  $H_2 A_1$  that is  $H_2$  into this  $A_1$  has the form that in the first column all the entries before the diagonal term is 0 and in the second column entries below the diagonal terms are 0 means these entries are 0 and all others may be untouched.

So, to find out this  $\hat{H}_2$  we look at this second column and look at these entries 21.4516, 10.1935, 11.8710 and what we want to make here that it is these entries this second entries this is non zero and these entries are 0. So, these entries we want that should be 0. So, to define  $\hat{H}_2$  we define  $\hat{H}_2$  as  $I_3 - 2\hat{w}_2 \hat{w}_2^T$  and we have this is  $x$  and  $y$  is minus of 1 0 0 and again using the algorithm we can find out  $\hat{w}_2$  and we can say that  $\hat{w}_2$  is nothing, but this that we can also look at here.

(Refer Slide Time: 24:34)

Thus,  $H_2$  is defined as

$$H_2 = \begin{bmatrix} I_1 & 0 \\ 0 & \hat{H}_2 \end{bmatrix}$$

i.e.  $H_2 = I_4 - 2w_2w_2^T$ , where

$$w_2 = \begin{bmatrix} 0 \\ \hat{w}_2 \end{bmatrix} \in \mathbb{R}^4$$

Therefore, we have

$$A_2 = H_2A_1 = \begin{bmatrix} -19.0000 & -6.0000 & 7.2105 & 8.7895 \\ 0.0000 & -26.5518 & -12.9280 & -4.2836 \\ 0.0000 & 0 & -12.4450 & 7.5813 \\ 0.0000 & 0 & 14.1420 & -22.5149 \end{bmatrix}$$

◻

IFT ROORKEE    NPTEL ONLINE CERTIFICATION COURSE    14

So, once we have  $w_2$  hat then we can define  $w_2$ ,  $w_2$  is nothing, but  $0$   $W_2$  hat and once we define  $w_2$  then we can write  $H_2$  as  $I_4$  minus  $2$   $\omega_2$   $\omega_2$  transpose and we have already seen that this  $H_2$  will have this form,  $H_2$  as  $I_1$ ,  $0$ ,  $0$ ,  $H_2$  hat and if we operate  $H_2$  on this  $A_1$  then we have this form that in first column entries below the diagonal term it is all  $0$  and the second column also entry below the diagonal term that is this term all entries are  $0$ .

So, that is the effect of  $H_2$ . So, here you can find out this  $w_2$  hat with the help of algorithm and then we can define  $w_2$  with this setting that it is  $0$   $w_2$  hat once we have  $w_2$  then we can define  $H_2$  as  $I_4$  minus  $2$   $\omega_2$   $\omega_2$  hat and we can have  $H_2$ , so once we have  $H_2$  we can write  $A_2$  as  $H_2$  into  $A_1$ . So, here we have this form. Now what we want we need to find out  $H_3$ , so that  $A_3$  which is given as  $H_3A_2$  has the following form.

(Refer Slide Time: 25:41)

Step 3: Here, we find  $H_3$  so that  $A_3 = H_3 A_2$  has the form

$$A_3 = H_3 A_2 = H_3 \begin{bmatrix} -19.0000 & -6.0000 & 7.2105 & 8.7895 \\ 0.0000 & -26.5518 & -12.9280 & -4.2836 \\ 0.0000 & 0 & -12.4450 & 7.5813 \\ 0.0000 & 0 & 14.1420 & -22.5149 \end{bmatrix} = \begin{bmatrix} * & * & * & * \\ 0 & * & * & * \\ 0 & 0 & * & * \\ 0 & 0 & 0 & * \end{bmatrix}$$

First, we find  $\hat{H}_3$  so that

$$\hat{H}_3 = I_2 - 2\hat{w}_3\hat{w}_3^T$$

where

$$\hat{w}_3 = \begin{bmatrix} -0.9112 \\ 0.4119 \end{bmatrix}$$

Thus  $H_3$  is defined by

$$H_3 = \begin{bmatrix} I_2 & 0 \\ 0 & \hat{H}_3 \end{bmatrix}$$

15

So, here  $A_3$  is equal to  $H_3 A_2$  as this,  $A_2$  we have just calculated as this, we write it here and what we want that this entry has to be 0, it means that we have this form that in first column these three are 0, in second column these two are 0, in third column this entry has to be 0, means this we want to replace by 0. So, for that we define  $\hat{H}_3$ ,  $\hat{H}_3$  is  $I_2 - 2\hat{w}_3\hat{w}_3^T$ , how to find on this  $\hat{w}_3$ , this  $\hat{w}_3$  is this is your  $x_3$  and  $y_3$  is 1 0 and  $\hat{H}_3$  will map this minus 12.4450, 14.1420 to 1 0.

So, for that you can find out  $\hat{w}_3$  as  $\frac{x_3}{\|x_3\|}$  that is we are using algorithm that is all we want to say. So, once we have  $\hat{w}_3$  that is minus 0.9112, 0.4119 then we can define  $H_3$  as  $I_2, 0, 0, \hat{H}_3$ , where  $\hat{H}_3$  is defined by  $I_2 - 2\hat{w}_3\hat{w}_3^T$ . Let us just verify that  $\hat{w}_3$  is given by this and  $H_3$  we can calculate in what form. So, to find out this  $\hat{w}_3$  we need to find out that your  $\hat{H}_3$  will send this to 1 0, so, here it is minus 12.4450, so let me write it as  $\frac{x_3}{\|x_3\|}$ , (Refer Time: 27:49) so, we need to find out this  $\hat{w}_3$ .

So, here we let us try to find out this  $\hat{H}_3$  which have this effect that it make these 2 entries as a some non zero into entries and 0 entries. We need to find out such  $\hat{H}_3$  where  $\hat{H}_3$  is  $I_2 - 2\hat{w}_3\hat{w}_3^T$ , we can find out like this and once we have  $\hat{w}_3$ .

(Refer Slide Time: 28:23)

i.e.  $H_3 = I_4 - 2w_3w_3^T$ , where

$$w_3 = \begin{bmatrix} 0 \\ \hat{w}_3 \end{bmatrix} \in \mathbb{R}^4$$

Therefore, we have

$$R = A_3 = H_3A_2 = \begin{bmatrix} -19.0000 & -6.0000 & 7.2105 & 8.7895 \\ 0.0000 & -26.5518 & -12.9280 & -4.2836 \\ 0.0000 & 0 & 18.8381 & -21.9106 \\ 0.0000 & 0 & 0.0000 & -9.1826 \end{bmatrix}$$

and

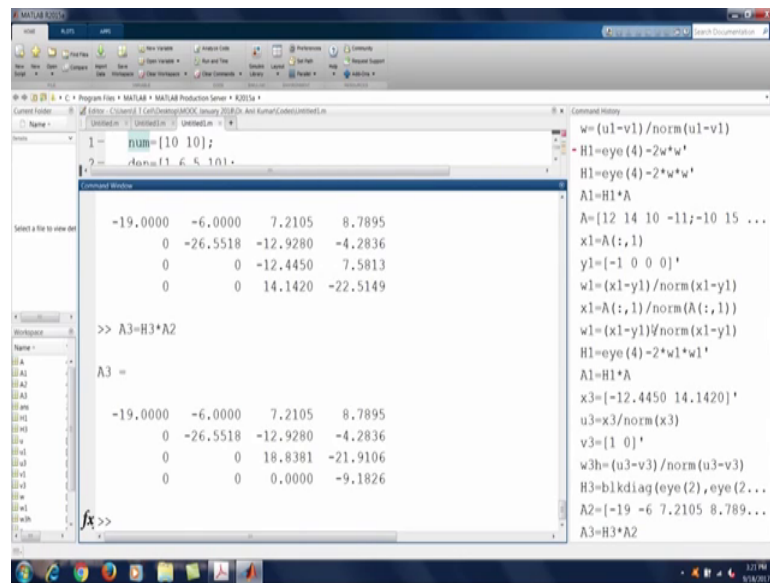

$$Q = H_1H_2H_3 = \begin{bmatrix} -0.6316 & -0.3846 & 0.5087 & -0.4410 \\ 0.5263 & -0.6839 & -0.2461 & -0.4413 \\ -0.4737 & -0.4956 & -0.5304 & 0.4988 \\ 0.3158 & -0.3727 & 0.6320 & 0.6017 \end{bmatrix}$$

16

Then we can define  $H_3$  as a blocked diagonal matrix  $I_2, 0, 0, H_3$  hat and once we have  $H_3$  then we can find out  $A_3$  as  $H_3A_2$  and which have this form. If you look at this form, this is an upper triangular matrix. So, here we stop and we say that this is our upper triangular matrix, we call this as  $R$ , so  $R$  can be written as  $A_3$  and  $A_3$  is nothing but  $H_3A_2$  and we can write down the expression for  $A_2$  that is a  $H_2$  basically it is  $H_2A_1$  and  $A_1$  we can write it  $H_1A$ .

So, we can write this  $R$  as  $H_3, H_2, H_1A$  and we can write  $Q$  as  $H_1, H_2, H_3$  and this is given by this. So, it means that we can find out our  $Q$  and  $R$ . So, let us stop a little bit here and we try to show that how we can find out this  $\hat{w}_3$  which makes this entry to 0 0 entries here.

(Refer Slide Time: 29:25)

The screenshot shows the MATLAB environment with the following code and results:

```
1 - DUM=[10 10];
2 - A=[1 1 6 5; 10 1];

Command Window:
-19.0000 -6.0000 7.2105 8.7895
0 -26.5518 -12.9280 -4.2836
0 0 -12.4450 7.5813
0 0 14.1420 -22.5149

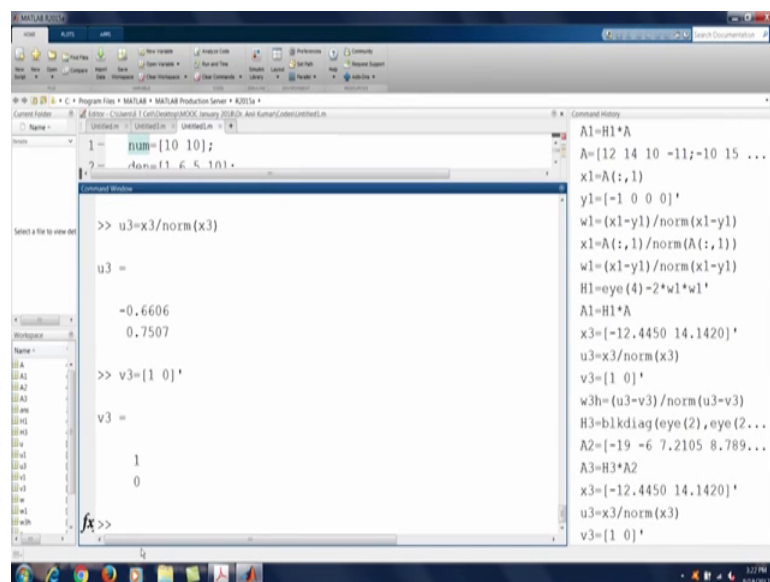

>> A3=H3*A2

A3 =
-19.0000 -6.0000 7.2105 8.7895
0 -26.5518 -12.9280 -4.2836
0 0 18.8381 -21.9106
0 0 0 0.0000 -9.1826

Command History:
w=(u1-v1)/norm(u1-v1)
H1=eye(4)-2*w*w'
H1=eye(4)-2*w*w'
A1=H1*A
A=[12 14 10 -11;-10 15 ...
x1=A(:,1)
y1=[-1 0 0 0]'
w1=(x1-y1)/norm(x1-y1)
x1=A(:,1)/norm(A(:,1))
w1=(x1-y1)/norm(x1-y1)
H1=eye(4)-2*w1*w1'
A1=H1*A
x3=[-12.4450 14.1420]'
u3=x3/norm(x3)
v3=[1 0]'
w3h=(u3-v3)/norm(u3-v3)
H3=blkdiag(eye(2),eye(2)...
A2=[-19 -6 7.2105 8.789...
A3=H3*A2
```

So, let us do it in An algorithm. So, here we first defined what is x3 here , So let us say the x3 is this minus 12.4450, 14.1420 that is here, minus 12.4450, 14.1420, but if you look at this x3 is not a unit vector, so for that we need to find out a unit vector.

(Refer Slide Time: 29:51)

The screenshot shows the MATLAB environment with the following code and results:

```
>> u3=x3/norm(x3)

u3 =
-0.6606
0.7507

>> v3=[1 0]'

v3 =
1
0

Command History:
A1=H1*A
A=[12 14 10 -11;-10 15 ...
x1=A(:,1)
y1=[-1 0 0 0]'
w1=(x1-y1)/norm(x1-y1)
x1=A(:,1)/norm(A(:,1))
w1=(x1-y1)/norm(x1-y1)
H1=eye(4)-2*w1*w1'
A1=H1*A
x3=[-12.4450 14.1420]'
u3=x3/norm(x3)
v3=[1 0]'
w3h=(u3-v3)/norm(u3-v3)
H3=blkdiag(eye(2),eye(2)...
A2=[-19 -6 7.2105 8.789...
A3=H3*A2
x3=[-12.4450 14.1420]'
u3=x3/norm(x3)
v3=[1 0]'
```

So, let us call this as u3, u3 is nothing but x3 divided by norm of x3 and that makes this as a unit vector. So, it is minus 0.6606 and 0.7507. Now we want to define v3 unit vector and that is given by minus sign of this, now sign of this is basically this is negative. So,

$v_3$  is going to be nothing, but a 1 0. So,  $v_3$  is this. Now once we have  $u_3$ ,  $v_3$  then we can define our  $w_3$ , since here we are using  $w_3$ .

(Refer Slide Time: 30:23)

```

1 - num=[10 10];
2 - A=[1 1 6 5; 10 1];

>> v3=[1 0]';

v3 =

     1
     0

>> w3h=(u3-v3)/norm(u3-v3)

w3h =

    -0.9112
     0.4119
  
```

So  $w_3$  hat is given by  $u_3$  minus  $v_3$  divided by norm of  $u_3$  minus  $v_3$  and it is coming out to be this  $w_3$  hat is equal to minus 0.9112, 0.4119 and that is what it is written here,  $w_3$  hat as minus 0.9112, 0.4119. So, once we have  $w_3$  hat with us

(Refer Slide Time: 30:55)

```

>> H3=blkdiag(eye(2), eye(2)-2*w3h*w3h');

H3 =

    1.0000    0         0         0
         0    1.0000    0         0
         0         0   -0.6606    0.7507
         0         0    0.7507    0.6606
  
```

Then we can define our  $H_3$ , so,  $H_3$  is given by , we need to define first of all  $H_3$  hat and  $H_3$  is what,  $H_3$  hat is basically  $I_2$ , this is your  $H_3$  hat, that is  $I_2$  minus 2  $\omega_3 \omega_3$

$\hat{H}_3$   $\hat{\omega}_3$   $\hat{H}_3^T$  and once we have  $\hat{H}_3$  then we can write  $\hat{H}_3$  as a block diagonal matrix like this. So, let us write  $\hat{H}_3$  as the following thing and this is the representation of a writing a block diagonal matrix.

So, this is the command block blk diag block diagonal matrix where the first diagonal is  $I_2$  that will give you the identity matrix of size 2 cross 2. The remaining diagonal entries are  $I_2 - 2\hat{\omega}_3$  into  $\hat{\omega}_3^T$ , that is nothing, but your  $\hat{H}_2$ . So, you should calculate your  $\hat{H}_3$  is coming by this. So, this will represent your  $\hat{H}_3$ , so once we have  $\hat{H}_3$  we can define  $\hat{H}_3$  as the  $I_2$ , this  $\hat{H}_3$  hat 0 0.

(Refer Slide Time: 32:11)

So, once we have  $\hat{H}_3$  then we can calculate our  $A_3$ , our  $A_3$  is basically what,  $A_3$  is basically your  $\hat{H}_3$  into  $A_2$ , where  $A_2$  is what,  $A_2$  we already know, using this  $A_2$  is given by this. So, we can write  $A_3$  as  $\hat{H}_3$  into  $A_2$  and that is this thing  $A_3$  is minus 19.0000, minus 6.0000 and minus 26.5518 and here 0. And if you look at the third column here, 7.2105, minus 12.9280 and if you look at the last term is 0 and this is maybe non 0.

So, here we call this  $A_3$  as  $R$  here and that is what we have done here, we have defined  $R$  as  $A_3$ , because now it has this upper triangular form and  $Q$  as the product of  $H_1, H_2, H_3$ . Now, since each one is symmetric and each one is orthogonal, so  $Q$  is your orthogonal matrix and  $R$  is also in upper triangular form, so we can write  $U^T A$  as this  $Q$  into  $R$ . So, that will complete the verification part of this theorem and here one thing you may note it down.

(Refer Slide Time: 33:27)

The screenshot shows the MATLAB Command Window with the following content:

```

>> A=
A =
     1
Error: Expression or statement is incomplete or incorrect.

>> A
A =

    12    14    10   -11
   -10    15     8    17
     9    16    -7     5
    -6     8    19   -15
  
```

The Command History on the right shows a sequence of operations: `x1=A(:,1)/norm(A(:,1))`, `w1=(x1-y1)/norm(x1-y1)`, `H1=eye(4)-2*w1*w1'`, `A1=H1*A`, `x3=x3/norm(x3)`, `u3=x3/norm(x3)`, `v3=[1 0]'`, `w3h=(u3-v3)/norm(u3-v3)`, `H3=bkdiag(eye(2),eye(2))`, `A2=[-19 -6 7.2105 8.789...]`, `A3=H3*A2`, `x3=[-12.4450 14.1420]'`, `u3=x3/norm(x3)`, `v3=[1 0]'`, `w3h=(u3-v3)/norm(u3-v3)`, `H3=bkdiag(eye(2),eye(2))`, `A3=H3*A2`, `A=A`, and `A`.

That your matrix A is here this and we try to find out this Q and R then this is command here this Q and R , you can write it here as QR of A.

(Refer Slide Time: 33:21)

The screenshot shows the MATLAB Command Window with the following content:

```

Q =

-0.6316   -0.3846   0.5087   -0.4410
 0.5263   -0.6839  -0.2461   -0.4413
-0.4737   -0.4956  -0.5304   0.4988
 0.3158   -0.3727   0.6320   0.6017

R =

-19.0000   -6.0000   7.2105   8.7895
 0   -26.5518  -12.9280  -4.2836
 0     0   18.8381  -21.9106
 0     0     0   -9.1826
  
```

The Command History on the right shows the same sequence of operations as in the previous screenshot, ending with `[Q R]=qr(A)`.

So, this is the command of (Refer Time: 33:52) command, this will give you the upper triangular matrix that is R and if you look at this R and A3R seen here, we have seen your R that we have obtained through the proof of the theorem. And if you look at here, we have just used a command QR of A and that will give you the value RM and Q here is this and the matrix that is your H1 into H2 into H3 that is your Q. So, this command QR

equal to QR of A that will give you the QR decomposition of a given matrix A. So, here I will stop and in next lecture we will discuss the uniqueness of this, QR factorization and how to find out the QR decomposition of a rectangular matrices and once we are done with this QR decomposition method then we will see some application of this QR decomposition as in the problem of Eigenvalue problem. So, here I will stop. Thank you for listening us.

Thank you.
