Lecture - 07
Bases and Dimensions-I

Hello, friends welcome to the lecture and in this lecture we will discuss some concept about basis and dimension, and if you recall in previous lecture we have discussed what do we mean by a basis. So, there we started with a vector space say V defined on a field F .

(Refer Slide Time: 00:41)

And we say that B is a basis of say V if 2 things satisfy first thing is that the span of B is whole of V , and second thing is that B is a LI set and as an example, we have discussed certain cases. First example, we have seen as set of all \mathbb{R}^n basically set of all n cross 1 vectors. So, \mathbb{R}^n and here we have seen that this E_{ij} equal to i is from 1 to n less than i less than n is a basis here E_{ij} is nothing, but E_{ij} is equal to 0 say 1.

So, here we have at i th place we have 1 so here we have this is i th place, i th place. So, we have seen that that in \mathbb{R}^n this set is a basis and it is known as standard basis for \mathbb{R}^n , similarly we have seen another example of set of all polynomials of power of degree not more than F , and here we have seen that set $1, x, \dots, x^n$, the set forms a basis for set of all polynomials whose degree is up to n and here we have shown that this act as a basis and.

It is also known as standard basis for this at $P_n(F)$ and we also seen the vector space of matrices of size m cross n defined over this F , and here we have shown that E_{ij} is from 1 to m and j is from 1 to n , forms a basis for this vector space. So, here E_{ij} is basically what E_{ij} is a matrix whose only nonzero entry is 1 at the position which is i th j th position. So, at ij th position it is 1 rest all 0 , so ij th position means i th row and j th column.

So, this we have discussed in last class now in continuation of this institution, let us consider a next theorem which says that V if let V be a vector space.

(Refer Slide Time: 03:29)

Theorem 1

Let V be a vector space and $\beta = \{u_1, u_2, \dots, u_n\}$ be a subset of V . Then β is a basis for V if and only if each $v \in V$ can be uniquely expressed as a linear combination of vectors of β or in other words V can be expressed in the form

$$v = a_1 u_1 + a_2 u_2 + \dots + a_n u_n$$

for unique scalars a_1, a_2, \dots, a_n .

Proof. Let β be a basis for V . If $v \in V$, then $v \in \text{span}(\beta)$ as $\text{span}(\beta) = V$. Thus v is a linear combination of the vectors of β . Suppose that

$$v = a_1 u_1 + a_2 u_2 + \dots + a_n u_n$$

and

$$v = b_1 u_1 + b_2 u_2 + \dots + b_n u_n$$

are two representations of v . Then

And β be a subset of V β consists of these element u_1 to u_n , then β is a basis for V if and only if for each V a vector in vector space V , we have a unique representation of V or we can say that each vector in V can be uniquely expressed as a linear combination of vectors of β or in other words V can be expressed in the form v equal to $a_1 u_1$ plus $a_2 u_2$ plus $a_n u_n$ for unique scalars a_1 to a_n .

So, it means that if we take any vector in vector space V , then corresponding to this vector we have unique scalars a_1 to a_n says that we can be written as a linear combination of these $a_i u_i$. So, this we wanted to prove and this is if and only if result. So, first let us prove here that let β be a basis and then we try to find out that we have a unique representation. So, just assume that β is a basis and take any element in vector space V , then v belongs to a span of β because a span of since β is a basis

then a span of beta is whole of V and V is a element of capital V. So, it means that V has to be a element of a span of beta

So, it means that V can be written as linear combination of the vectors of beta now let us assume that we may have more than 1 representation it means that V can be written as summation $a_i u_i$ i is from 1 to n, and we can also write V in terms of $b_i u_i$ from i is 1 to n, now we want to claim that these 2 representation is nothing, but the same representation it means that E_i is same as b m.

So,, so let us take these 2 representation and we subtract these 2 representation and we can have when we subtract here V minus V is simply 0 and here in the right hand side what we have $a_1 - b_1$ times u_1 plus $a_2 - b_2$ times u_2 and so on ah.

(Refer Slide Time: 05:43)

$0 = (a_1 - b_1)u_1 + (a_2 - b_2)u_2 + \dots + (a_n - b_n)u_n.$

Since β is linearly independent, it follows that
 $a_1 - b_1 = a_2 - b_2 = \dots = a_n - b_n = 0.$
Hence $a_i = b_i$, $1 \leq i \leq n$, and so v is uniquely expressible as a linear combination of the vectors of β . Converse is trivially true.

3

And we can get this kind of equation that 0 can be written as $a_1 - b_1$ into u_1 plus $a_2 - b_2$ into u_2 and so on. Now this implies that 0 has ah representation in terms of u_1 to u_n , now since u_1 to u_n forms a basis it means that u_1 to u_n are linearly independent vectors.

So, this implies that that 0 must have only a trivial representation it means what that the coefficient of u_i is nothing, but 0. So, if coefficient of u_i is 0 means $a_i - b_i$ is equal to 0 $a_1 - b_1$ is equal to 0 $a_2 - b_2$ is equal to 0 similarly $a_n - b_n$ is equal to 0, and this simply these and equations will give you that a_i equal to b_i for all i from 1 to n.

So, it means that all constants a_i is equal to b_i . So, it means that these 2 representation is nothing, but same representation. So, it means that if we have a basis then any vector can be represented in terms of basis vectors, in a unique manner now let us move the converse part. So, converse part is quite trivial, but let us have a small hint here, so, what we want to prove here that if we can any vector V can be written as unique representation in terms of elements of β then β has to be a basis here, so now we want to prove that if any vector V .

(Refer Slide Time: 07:21)

The image shows a whiteboard with the following handwritten text:

$$\beta = \{u_1, \dots, u_n\}$$

$$v \in V \quad v = \sum_{i=1}^n a_i u_i \quad a_i, 1 \leq i \leq n, \text{ are unique.}$$

$$\text{Span}(\beta) = V$$

$$0 \cdot u_1 + 0 \cdot u_2 + \dots + 0 \cdot u_n = 0 = \sum_{i=1}^n a_i u_i$$

$$\Rightarrow a_i = 0 \quad \forall i = 1, \dots, n.$$

In vector space V has unique representation in terms of elements of this set β here then this set β is nothing, but basis for this vector space V . So, here V has a unique representation means V can be written as summation $a_i u_i$ i is from 1 to n and these a_i 's are unique a_i i from 1 to n $1 \leq i \leq n$ all these are unique scalars.

Now to using this we want to show that this set β is a basis for this, now since it is already given that any vector V can be written as unique in a unique manner in terms of vectors of β it means that a span of β is full of V . So, it means that any vector can be written as inner combination of n elements of β it means that a span of β is whole of V , the only thing we want to prove is that this β is a linearly independent set.

So, for that we start with 0 and we try to find out say 0 as a linear combination of u_i . So, here let us say that 0 can be written as sum $a_i u_i$ i is from 1 to n , we want to show that if this all a_i are 0 then we can show that u_i are linearly independent. So, this can

be easily achieved by saying that this 0 has another representation, representation in terms of u is that 0 times v_1 plus 0 times u_2 and so on.

Now, we already know that every vector has unique representation means this representation is nothing different from this representation. It means that if we equate the corresponding coefficient corresponding coefficient has to be 0 . So, a_i has to be 0 for all i equal to 1 to see n . So, here this implies that that if we take summation $a_i u_i$ equal to 0 , then all a_i has to be 0 which shows that all u_i are linearly independent is that.

So, this shows that if every vector V of a vector space V , can be uniquely represented in terms of elements of this set β here, then β has to be a basis of this vector space V this is very, very important result in terms of β in, in terms of forming a basis that if we have a finite generating set. Then our vector space V can be generated by a finite set and β , we can find out a basis from this finite set which is a generating set.

So, here we try to find out that a, a, a, a generating set a finite generating set S can be reduced to find out a basis of this vector space V . So, let us look at the proof of this, so here let us consider the trivial case, so let us say that if S is empty set.

(Refer Slide Time: 10:49)

Theorem 2

If a vector space V is generated by a finite set S , then some subset of S is a basis for V . Hence V has a finite basis.

Proof. If $S = \emptyset$ or $S = \{0\}$, then $V = \{0\}$ and $\emptyset \subseteq S$ is a basis of V .
 Let S contains a nonzero vector say v_1 and $\{v_1\}$ is a linearly independent set.
 Choose $v_2 \notin \text{Span}\{v_1\}$, then $\{v_1, v_2\}$ is a linearly independent set. Proceeding in this manner let us construct a subset $\beta := \{v_1, v_2, \dots, v_k\}$ such that β is a linearly independent set and by adding any vector in β we have a linearly dependent set (S is a finite set). Now our claim is that $\beta \subseteq S$ is a basis for V . To show this we will show that $S \subseteq \text{Span}\{\beta\}$. Let $u \in S$, if $u \in \beta \in \text{Span}\{\beta\}$. If $u \notin \text{Span}\{\beta\}$ then construction shows that $\beta \cup \{u\}$ is linearly dependent. So $u \in \text{Span}\{\beta\}$. Thus $S \subseteq \text{Span}\{\beta\}$.

NPTEL ONLINE
CERTIFICATION COURSE
4

Or singleton 0 in this case a span of S is nothing, but 0 . So, it means that since V is generated by this is finite set S . So, it means that in this case V is nothing, but a trivial

vector space and in this case if V is a trivial vector space then we already seen that in this case our species ah set is nothing, but empty set. So, we can set that embady empty set, which is a subset of this S . In fact, empty set is a subset of each set, so we can say that empty set is a basis of V . So, in case of when S is empty set or singleton 0 set, then we can say that basis of V can be written as nothing, but this empty set.

Now, let us move to nonzero ah non-trivial case, so let us say that let S contains a nonzero vector say V_1 , now since V_1 is nonzero, we already know that V_1 is linearly independent set that is clear from the remark given in previous lecture. So, first remark if you remember, then now let us extend this singleton set to the basis of vector space V . So, now let us choose another vector say V_2 of V now this V_2 we are choosing in a way says that it is not belonging to the span of this singleton V_1 .

So, it means that V_2 can mean cannot be written as linear combination of this V_1 , then way we have already seen that in this case this V_1 union V_2 is a linearly independent set, that is to will from the proof from a theorem which we have proved in a previous class that if we start with a linearly independent set say S . And if we take any element which which is not in S , then S union V is l d if and only if V belongs to span of S .

So, here using that result we can show that if we choose V_2 which is not belonging to span of V_1 , then V_1 union V_2 is a l i set. So, ah using this procedure we can proceed and we can find out a set subset beta of set S , consisting V_1 to V_k such that beta is linearly independent set. And by adding any vector in beta we have a linearly dependent set, and this we can ah always achieve because S is a finite set.

So, it means that it can go up to this set S now here ah here I am assuming, that this set S is not a l i set, because if S is a l i set it is already a generating set then S is already a basis, we can say that S is already a basis then here we need not to go for them. So, here we are assuming that this S is not a l i set, so it means at s is l d set. So, it means that S is l d set S is a finite set then we can always find out a subset beta of this head says says that if we add any more vector in beta, we have a linearly dependent set this we can get from the previous theorem which we have discussed in previous class.

Now, our claim is that this set beta which is subset of this S is a basis for V . So, how we can prove we already know that this beta is l i by construction, what we need to prove here is that beta is span the whole of V . So, we need to prove that span of beta is whole

of V , so to show that we already know that the span of S is whole of V . So, if we can show that S is contained in a span of β then we can say that span of S is contained in span of β and so can say that V is nothing, but a span of β .

So, to show that S contained in a span of β let us take a element of this capital S . So, let us say this u belongs to this S now if u belongs to β , means if u is already in this set β , then u will automatically belongs to span of β . So, nothing we need not to prove anything, but if u is not belonging to a span of β . So, u belongs to S now if this u is already in this β then it will also belong to a span of β .

So, we can say that S belongs to a span of β , but if we can find out u which is not in a span of β . So, it means that u is not in a span of β , then by previous theorem we can say that u union β is a linearly independent set, but our construction shows that β union u is a linearly dependent set as we have already constructed our β in a way, that if we add any more vector it will be a linearly dependent set, but by previous theorem we can say that if u does not belong to span of β then by taking u along with this β will give you a linearly independent set.

So, here we can get a contradiction and this contradiction we are getting because we are assuming that u does not belong to a span of β . So, u belongs to a span of β and we can say that if u belongs to span of β means S belongs to span of β it means that a span of β is nothing, but whole of space vector space V . So, it means that this β is a subset of this S , which is a basis for this vector space V .

So, this complete the proof of this theorem and again reiterating the importance of this theorem too here, that if we start with a finite generating set S then every finite, this finite generating set can be reduced to a finite basis of this vector space V . So, now, let us move to again a very important theorem that is a replacement theorem which says that let V be a vector space.

(Refer Slide Time: 17:22)

The slide is titled "Replacement Theorem" in a blue header. Below the header, "Theorem 3" is presented in a blue box. The theorem text states: "Let V be a vector space that is generated by a set G containing exactly n vectors, and L be a linearly independent subset of V containing exactly m vectors. Then $m \leq n$ and there exists a subset H of G containing exactly $n - m$ vectors such that $L \cup H$ generates V ." Below the theorem, the "Proof" is given: "The proof is by mathematical induction on m . The induction begins with $m = 0$; for in this case $L = \phi$, and so taking $H = G$ gives the desired result. Now suppose that the theorem is true for some integer $m \geq 0$. We prove that the theorem is true for $m + 1$. Let $L = \{v_1, v_2, \dots, v_{m+1}\}$ be a linearly independent subset of V consisting of $m + 1$ vectors. Then $\{v_1, v_2, \dots, v_m\}$ is linearly independent,". At the bottom of the slide, there are logos for "IIT ROORKEE" and "NPTEL ONLINE CERTIFICATION COURSE", and the number "5" in the bottom right corner.

That is generated by a set G containing exactly n vectors, and let L be a linearly independent subset of V , containing exactly m vectors then m has to be less than or equal to n what is m here m is number of vectors in linearly independent subset of V . And n is what n is the number of element in a spanning set then m has to be less than or equal to n and, there exist a subset H of G containing exactly n minus m vectors, such that L union that subset H of G generate the whole of V .

Now, this can be understood in a way ah, if you look at the previous theorem previous theorem says that a finite generating set can be reduced to a basis. Now this theorem says that we start with a linearly independent subset of V and we can extend it to the basis of a vector space V . So, previous theorem says the construction of basis from a generating set, and this theorem says the construction extension of set a linearly independent set to a basis of a vector space V both are very, very important.

So, the only thing is that from where we are starting, if we are starting from generating set look at the previous theorem and if we are starting from linearly independent ah set then we can look at this a replacement theorem.

So, let us try to prove this theorem the proof is by mathematical induction on m . So, the induction begin with the say m equal to 0 , and if we consider the m equal to 0 means the number of element in this L i set is 0 . So, in this case we can say that L is nothing, but empty set. So, if L is empty set said we know that empty set is basically linearly

independent set, and span of L is nothing, but 0 . So, in this case your subset H of generating set G is nothing, but same. So, here we can take H as whole of G . So, it means that ϕ union with this G will generate whole of V , because it is already given that G is the generating set of this vector V , so which gives the desired result.

Now, let us assume that that theorem is true for some integer m which is positive, we try to prove that theorem is also true for next integer that is m plus 1 . So, let us assume this that let L is a linearly independent set, subset of V consisting of m plus 1 vectors, let us say a call these vectors as v_1 to v_{m+1} . So, if v_1 to v_m plus 1 this if this set is linearly independent, then any subset of this linearly independent subset is again linearly independent that we have already seen.

So, remove this v_{m+1} then we have v_1 to v_m and it is linearly independent, then if you look at the the assumption here then this by assumption we can say that this theorem is true for m . So, it means that this m is less than or equal to n , and for this set we can always find out we can find out a subset H of G containing exactly n minus m vector such that this set union that H generate the whole of V .

(Refer Slide Time: 21:04)

and so we may apply the induction hypothesis to conclude that $m \leq n$ and that there is a subset $\{u_1, u_2, \dots, u_{n-m}\}$ of G such that $\{v_1, v_2, \dots, v_m\} \cup \{u_1, u_2, \dots, u_{n-m}\}$ generates V . Thus there exist scalars $a_1, a_2, \dots, a_m, b_1, b_2, \dots, b_{n-m}$ such that

$$\sum_{i=1}^m a_i v_i + \sum_{j=1}^{n-m} b_j u_j = v_{m+1}. \quad (1)$$

If v_{m+1} is a linear combination of v_1, v_2, \dots, v_m , only then this contradicts the assumption that L is linearly independent. Hence $n > m$; that is, $n \geq m + 1$. This imply that some of the b_j , say b_1 , is nonzero. Solving (1) for u_1 gives

6

so it means that we may apply the induction hypothesis to conclude that m is less than or equal to n and that there is a subset u_1 to u_{n-m} of G such that this set union u_1 to u_{n-m} generates the whole of V .

Now, with this we want to prove the result for this set L . So, now, since this spans the whole of V . So, in particular we can always find out say constant a_1 to a_{m+1} to b_{n-m} , such that this vector v_{m+1} can be written as linear combination of v_1 to v_m and u_1 to u_{n-m} .

Now here my claim is that there exist at least one b_j 's, which are nonzero because if all b_j for $j=1$ to $n-m$ are 0 it means that v_{m+1} can be written as a linear combination in terms of v_1 to v_m , which contradicts the fact that L is linearly independent because L is linearly independent means v_{m+1} cannot be written as a linear combination of v_1 to v_m . So, at least one of this b_1 to b_{n-m} has to be nonzero, it means that this $n-m$ has to be positive then only some of b_j 's are non zero.

So, here n is strictly greater than m or we can say that n is greater than or equal to $m+1$ this implies that some of the b_j 's let us say at least one b_j is non 0 and then we can write down equation 1 in terms of b_j . So, $b_1 u_1$ we can write it $b_1 u_1$ in terms of $a_i v_i$ and v_{m+1} .

(Refer Slide Time: 22:57)

$$u_1 = -\sum_{i=1}^m b_i^{-1} a_i v_i + b_{m+1}^{-1} v_{m+1} - \sum_{j=2}^{n-m} b_j^{-1} b_j u_j$$

Let $H = \{u_2, u_3, \dots, u_{n-m}\}$. Then $u_1 \in \text{span}(L \cup H)$, and because $v_1, v_2, \dots, v_m, u_2, u_3, \dots, u_{n-m}$ are clearly in $\text{span}(L \cup H)$, it follows that

$$\{v_1, v_2, \dots, v_m, u_1, u_2, \dots, u_{n-m}\} \subseteq \text{span}(L \cup H).$$

Because $\{v_1, v_2, \dots, v_m, u_1, u_2, \dots, u_{n-m}\}$ generates V , so $\text{span}(L \cup H) = V$. Since H is a subset of G that contains $(n-m) - 1 = n - (m+1)$ vectors, the theorem is true for $m+1$ vectors. Hence the proof follows.

NPTEL ONLINE CERTIFICATION COURSE
7

And we can write it u_1 as minus summation i equal to 1 to m $b_i^{-1} a_i v_i$ plus $b_{m+1}^{-1} v_{m+1}$ minus j equal to 2 to $n-m$ $b_j^{-1} b_j u_j$

So, it means that u_1 can be written as linear combination of v_1 to v_m and u_j 's, and we can say that let us consider H now in this case H is nothing, but remove this u_1 from

this set u_1 to u_{n-1} now h is what u_2 to u_{n-1} . Then u_1 belongs to span of L union H is what L is v_1 to v_{m+1} h is what u_2 to u_{n-1} . So, we have shown that u_1 can be written as the linear combination of v_i 's v_{m+1} and u_j . So, we can say that u_1 belongs to a span of L union H and because v_1 to v_m u_1 to u_{n-m} these are already in span of an union H basically these are element of L union H , so this will belongs to a span of H .

So, it follows that v_1 to v_m u_1 to u_{n-m} it also belongs to a span of L union H , since this theorem is true for all vectors v_1 to v_m , then this set generate the whole of v . So, we are using this fact and we are saying that v_1 to v_m u_1 to u_{n-1} generates v . So, and this is already contain in span of a L union H . So, it means that v containing a span of L union H . So, we can say that span of L union H is whole of v .

So, since H is subset of G now how many element it contain it contains $n - m - 1$. So, it means it contains $n - m + 1$ vectors and the theorem is true for $m + 1$ vectors also, and hence the proof follows.

(Refer Slide Time: 25:00)

Replacement Theorem

Theorem 3

Let V be a vector space that is generated by a set G containing exactly n vectors, and L be a linearly independent subset of V containing exactly m vectors. Then $m \leq n$ and there exists a subset H of G containing exactly $n - m$ vectors such that $L \cup H$ generates V .

Proof. The proof is by mathematical induction on m . The induction begin with $m = 0$; for in this case $L = \phi$, and so taking $H = G$ gives the desired result. Now suppose that the theorem is true for some integer $m \geq 0$. We prove that the theorem is true for $m + 1$. Let $L = \{v_1, v_2, \dots, v_{m+1}\}$ be a linearly independent subset of V consisting of $m + 1$ vectors. Then $\{v_1, v_2, \dots, v_m\}$ is linearly independent,

Now, this has a very, very say useful corollaries which we are going to discuss, so first ah corollary is this that.

(Refer Slide Time: 25:11)

Dimension

Corollary 4
 Let V be a vector space having a finite basis. Then every basis for V contains the same number of vectors.

Definition 1
 A vector space is called **finite-dimensional** if it has a basis consisting of finite number of vectors. The unique number of vectors in each basis is called the **dimension** of V and is denoted by $\dim(V)$. A vector space that is not finite-dimensional is called **infinite-dimensional**.

NPTEL ONLINE CERTIFICATION COURSE
8

Let V be a vector space having the finite basis then every basis for V contains the same number of vectors let us have a small proof of this. So, what we need to prove here that we have a.

(Refer Slide Time: 25:24)

$B = \{1\}$ $a, b \in \mathbb{C}$
 $\mathbb{C}(\mathbb{C})$
 $\mathbb{C}(\mathbb{R})$ V has a finite basis.
 $u = a + ib$ $a, b \in \mathbb{R}$
 $\{1, i\}$ $\sum_{i=1}^n$ T m
 \mathbb{R}^n
 $B = \{e_i, 1 \leq i \leq n\}$
 $\dim(\mathbb{R}^n) = n$
 $P_n(F) = \{1, x, \dots, x^n\}$
 $\dim(P_n(F)) = n+1$
 (i) S is spanning set \rightarrow (i') T is a spanning set
 (ii) S is a LI set \leftarrow (ii') T is a LI set
 $n \leq m$ $\text{---} \textcircled{2}$ $m \leq n$ $\text{---} \textcircled{1}$
 $\Rightarrow m = n$

Vector space V and we know that it has a finite basis, has a finite basis, finite basis, what we want to prove here that every basis of this V contain the same number of vectors. So, suppose we have 2 basis say S and T , since it has a finite basis let us consider this finite

basis as this S . So, let us take the number of element in this basis is n and consider another basis say T and here the number of element is this m .

So, here since S is a basis it means that S is L I set, and S is a spanning set similarly T is a basis it means T is L I set and T is a spanning set. So, let us consider this as S is a spanning set means spanning set first second thing is that S is l a S is a L I set, similarly we can write down for T . So, that T is a spanning set a spanning set means span of T is whole of V and second is that T is L I set.

Now, please recall the replacement theorem and replacement theorem says that the number of that if we have a vector space V , and a spanning set having ah number less having number n and this n elements here then if we take any L I set, then number of L I independent vectors must be less than number of a spanning elements.

So, it means that here by a replacement theorem if we use these 2 result that if we have a S is a spanning set, means as generate the vector space V and T is a L I set, then the number of ah vectors in T must be less than or equal to number of the element in this spanning set. Now the number of element in L I set is m must be less than or equal to number of the element in this spanning set that is n . So, it means that m has to be less than or equal to n let us call this as equation number 1.

Now, let us consider again the same situation, but this time we use this set of ah things that in this case T is a spanning set, and S is a L I set. Now again use the replacement theorem which says that the number of number of vectors in a L I set, must be less than or equal to number the number of the element in a spanning set. Now here the number of element in L I set is what here the number of element in L I set is n this must be less than or equal to number of the element in a spanning set that is less than equal to.

So, n is less than or equal to m call it 2 now if we look at the both the equation number 1 and 2 this can be possible only when m is equal to n . So, it means that that if V has a finite basis then the number of element in any of the basis must be same, and this shows that that the number of basis element it means that number of basis may not be unique, but the number in each basis has to be unique and this number unique number assigned to this vector space V as a dimension of this vector space V .

So, let us with the help of this let us define the dimension of a vector space V . So, a vector space is called finite dimension if it has a basis consisting of finite number of vectors. And as we pointed out in this corollary 4 the unique number of vectors in each basis is called the dimension of V , and it is denoted by dimension of V .

Now if we do not have finite dimensional vector space then we call this as infinite dimension vector space, examples we have shown seen is \mathbb{R}^n and here we have seen a basis we have seen as e_i $1 \leq i \leq n$. So, here we can say that the dimension of \mathbb{R}^n is nothing, but n . So, dimension of \mathbb{R}^n is nothing, but n similarly dimension of $P_n(F)$ if we have seen that $P_n(F)$ is what $P_n(F)$ is the set of all polynomials whose degree less than or equal to n .

And we have seen that the basis element and basis are what $1, x, \dots, x^n$. So, here number of element is $n + 1$. So, we can say that dimension of $P_n(F)$ is nothing, but $n + 1$ is it they are certain more example here ah the trivial example is that.

(Refer Slide Time: 30:58)

The slide contains the following text:

Example 1
The vector space $\{0\}$ has dimension zero.

Example 2
The vector space \mathbb{R}^n has dimension n .

Example 3
The vector space $P_n(\mathbb{R})$ has dimension $n + 1$.

Logos for IIT ROORKEE and NPTEL ONLINE CERTIFICATION COURSE are visible at the bottom.

The vector space 0 has dimension 0 , so here ah we have defined as the. So, here ah basis set is nothing, but empty set and empty set has no element. So, we can say that vector space 0 has dimension 0 the next example which we just now shown that \mathbb{R}^n has dimension n . Similarly, the vector space $P_n(\mathbb{R})$ has dimension $n + 1$ now $P_n(\mathbb{R})$ means that set of all polynomials whose of degree less than or equal to n , whose coefficients are coming from real number is it ok, so here dimension is $n + 1$.

(Refer Slide Time: 31:35)

Example 4
Over the field of real numbers, the vector space of complex number has dimension 2. (A basis is $\{1, i\}$.)

Remark 1
The subspaces of \mathbb{R}^3 are easily seen as:
(a) 0-dimensional subspaces: $\{0\}$
(b) 1-dimensional subspaces: All lines through the origin
(c) 2-dimensional subspaces: All planes through the origin
(d) 3-dimensional subspaces: \mathbb{R}^3

IFT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 10

Next let us consider the example 4, which says that consider the vector space complex number and underlying field is real numbers. So, if underlying field is real number then we have basis vectors 1 and i . So, it means that you take any element in say \mathbb{C} over \mathbb{R} . So, \mathbb{C} over \mathbb{R} means you take any element here. So, let us call this as u here, so you can write and write down a plus i b , now since a and b are coming from where a and B are coming from \mathbb{R} right.

So, here basis elements are 1 and i , so we can say that ah this is 1 i and this can this spend the whole of vector space \mathbb{C} . So, we can say this is a basis element. So, here we can say that dimension of \mathbb{C} over \mathbb{R} is nothing, but 2, but if we consider the vector space \mathbb{C} over \mathbb{C} . So, it means that now the possibility for a and b that this a and b is coming from \mathbb{C} , then here basis element contain only 1 element that is any nonzero element let us take this as 1. So, here we have only singleton set which is spanned the whole of \mathbb{C} , and since, since it is a nonzero, so it will be a linearly independent set.

So, here \mathbb{C} over \mathbb{C} has dimension 1 while \mathbb{C} over \mathbb{R} has dimension 2. So, ah we can consider this subspace of \mathbb{R}^3 , and we can say that 0 dimensional subspace is $\{0\}$ 1 dimensional subspace we can consider all lines through the origin 2 dimensions away spaces all placed through the origin and 3 dimensional subspace is nothing, but \mathbb{R}^3 will discuss more about this remark in next lecture. So, here we skip we are skipping it and in

next lecture we will discuss more about it, and next important result is corollary 5 which says that.

(Refer Slide Time: 33:45)

Corollary 5
Let V be a vector space with dimension n .
(a) Any finite generating set for V contains at least n vectors, and a generating set for V that contains exactly n vectors is a basis for V .
(b) Any linearly independent subset of V that contains exactly n vectors is a basis for V .
(c) Every linearly independent subset of V can be extended to a basis for V .

Example 5
For $k = 0, 1, 2, \dots, n$, let $p_k(x) = x^k$ then $\{p_0(x), p_1(x), \dots, p_n(x)\}$ is a basis for $P_n(F)$ where $P_n(F)$ is vector space of all polynomials having degree less than or equal to n .

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 11

Let V be a vector space with dimension n then any finite generating set for V , which contains at least n vectors and a generating set for V that contain exactly n vectors is a basis. So, it means that if we already know the dimension here then if we can find out a generating set having exactly n vectors that is nothing, but a basis second thing be that any linearly independent subset of V that contains exactly n vectors is a basis for V , and third is that every linearly independent subset of V can be extended to a basis for V .

Now, we can consider as an example of this corollary 5 is this, then since it is L I set having $n + 1$ element which is nothing, but the dimension of $P_n(F)$. So, by second point of corollary 5 we can show that this set is a basis of $P_n(F)$ next lecture we will discuss the concept known as a coordinate of a given vector. So, how this concept of basis will help you to find out the coordinate of a given vector V is it ok. So, we will discuss in next lecture thank you for listening us we will meet in next class.

Thank you.
