Lecture - 13
Tangent Planes and Normal Lines

Hello friends. So, welcome to lecture series on multivariable calculus. So, we have already discussed so many properties of several functions in this lecture we deal with tangent planes and normal lines how can you find out tangent plane to a surface and a normal line at a point ok.

(Refer Slide Time: 00:45)

If $r = g(t)i + h(t)j + k(t)k$ is a smooth curve on the level surface $f(x, y, z) = c$ of a differentiable function f , then

$$f(g(t), h(t), k(t)) = c.$$

Differentiating both sides with respect to 't' we get

$$\frac{d(f(g(t), h(t), k(t)))}{dt} = \frac{d(c)}{dt}$$

$$\frac{\partial f}{\partial x} \frac{dg}{dt} + \frac{\partial f}{\partial y} \frac{dh}{dt} + \frac{\partial f}{\partial z} \frac{dk}{dt} = 0.$$

$$\left(\frac{\partial f}{\partial x} i + \frac{\partial f}{\partial y} j + \frac{\partial f}{\partial z} k \right) \cdot \left(\frac{dg}{dt} i + \frac{dh}{dt} j + \frac{dk}{dt} k \right) = 0$$

$$(\nabla f) \cdot \left(\frac{dr}{dt} \right) = 0$$

$$\Rightarrow (\nabla f) \perp \left(\frac{dr}{dt} \right).$$

NPTEL ONLINE
CERTIFICATION COURSE

2

So, first let us discuss this proof let r be given by a $g(t)i + h(t)j + k(t)k$ is a smooth curve on a level surface $f(x, y, z) = c$ on a differentiable function f ok.

(Refer Slide Time: 01:04)

Handwritten derivation on a whiteboard:

$$\nabla \equiv \hat{i} \frac{\partial}{\partial x} + \hat{j} \frac{\partial}{\partial y} + \hat{k} \frac{\partial}{\partial z} \quad \left| \quad f(x, y, z) = c \right.$$

del-operator

$$\nabla f = \hat{i} \frac{\partial f}{\partial x} + \hat{j} \frac{\partial f}{\partial y} + \hat{k} \frac{\partial f}{\partial z} \quad \left| \quad f[g(t), h(t), k(t)] = c \right.$$

gradient of f

$$r(t) = g(t)\hat{i} + h(t)\hat{j} + k(t)\hat{k}$$

$$\frac{dr}{dt} = \frac{dg}{dt}\hat{i} + \frac{dh}{dt}\hat{j} + \frac{dk}{dt}\hat{k}$$

$$\frac{\partial f}{\partial x} \frac{dx}{dt} + \frac{\partial f}{\partial y} \frac{dy}{dt} + \frac{\partial f}{\partial z} \frac{dz}{dt} = 0$$

$$\Rightarrow \left(\frac{\partial f}{\partial x} \hat{i} + \frac{\partial f}{\partial y} \hat{j} + \frac{\partial f}{\partial z} \hat{k} \right) \cdot \left(\frac{dx}{dt} \hat{i} + \frac{dy}{dt} \hat{j} + \frac{dz}{dt} \hat{k} \right) = 0$$

$$\Rightarrow (\nabla f) \cdot \frac{dr}{dt} = 0 \Rightarrow \nabla f \perp \frac{dr}{dt}$$

So, suppose you have some surface $f(x, y, z) = c$ suppose $r(t)$ which is given by $g(t)\hat{i} + h(t)\hat{j} + k(t)\hat{k}$, say this smooth curve passes through this surface. So, what will be the value of function on this surface? So, where f on this surface will be given by f you simply replace x by $g(t)$, y by $h(t)$ and z by $k(t)$. So, what you will obtain it is $g(t)h(t)k(t)$ is equals to c .

Now, you differentiate both sides respect to t when you differentiate both sides respect to t what will obtain. Now, we will apply a chain rule on this side this is ∇f upon $\frac{dr}{dt}$ because f is a function of x, y, z and x, y, z are intern are the function of t variable t . So, what you will obtain ∇f by $\frac{dx}{dt}$ plus ∇f by $\frac{dy}{dt}$ plus ∇f by $\frac{dz}{dt}$ which is equals to 0. So, I differentiate both sides respect to t ok. Now this can be written as ∇f by $\frac{dx}{dt}$ plus ∇f by $\frac{dy}{dt}$ plus ∇f by $\frac{dz}{dt}$ and dot with $\frac{dx}{dt}\hat{i} + \frac{dy}{dt}\hat{j} + \frac{dz}{dt}\hat{k}$ is equal to 0.

So, basically what is $\frac{dr}{dt}$ $\frac{dr}{dt}$ is same as $\frac{dx}{dt}$ is same as $\frac{dg}{dt}$ because x is simply $g(t)$ and y is simply $h(t)$ z is $k(t)$. So, $\frac{dx}{dt}$ is simply $\frac{dg}{dt}$ ok. Now what this is? This we call it we call this as gradient of f , we call this as gradient of f what is what is del operator del is $\hat{i}$ cap del by $\frac{\partial}{\partial x}$ plus $\hat{j}$ cap del by $\frac{\partial}{\partial y}$ plus $\hat{k}$ cap del by $\frac{\partial}{\partial z}$, this operator is called as del operator and del of f will be $\hat{i}$ cap del f by $\frac{\partial}{\partial x}$ plus $\hat{j}$ cap del f by $\frac{\partial}{\partial y}$ plus $\hat{k}$ cap del f by $\frac{\partial}{\partial z}$ ok.

So, this is simply this thing and we call it gradient of f ok. So, this is this we call as gradient of f dot with now what this is now when you find $\frac{d\mathbf{r}}{dt}$ of this equation of this vector. So, $\frac{d\mathbf{r}}{dt}$ will be $\frac{dg}{dt}\hat{i} + \frac{dh}{dt}\hat{j} + \frac{dk}{dt}\hat{k}$ now. So, this is same as this vector because $\frac{dx}{dt}$ is nothing, but $\frac{dg}{dt}$ because x is nothing, but g .

So, we can say that this vector is nothing, but $\frac{d\mathbf{r}}{dt}$ and this equal to 0 ok. Now this dot part is 0 this means the angle between them is dot product $\mathbf{a} \cdot \mathbf{b}$ is simply mod of $\mathbf{a}$ mod of $\mathbf{b}$ cos of angle between them and if cos of angle between them that is cos theta is 0. This means theta is $\pi/2$; that means, this vector is perpendicular to this vector. So, this implies gradient of f is perpendicular to $\frac{d\mathbf{r}}{dt}$.

Now, what $\frac{d\mathbf{r}}{dt}$ represent $\frac{d\mathbf{r}}{dt}$ represent velocity vector velocity vector of this smooth curve or we can say tangent at a point t $\frac{d\mathbf{r}}{dt}$; I mean a slope, sorry, which we can say a slope ok. Now this is perpendicular to ∇f ; that means, ∇f is normal to a surface because this is basically perpendicular to a tangent and if this is perpendicular tangent this means ∇f give normal to a surface if you have this type of surface this is f basically of 3 variable x, y, z then gradient of f at a point x, y, z simply give normal to the surface ok. So, we can say that at every point along the curve.

(Refer Slide Time: 06:20)

Continued...

At every point along curve, ∇f is orthogonal to the curve's velocity vector. Consider, all the curves that pass through a fixed point P_0 . Hence, all the velocity vectors at P_0 are orthonormal to $(\nabla f)_{P_0}$, so the curve's tangent lines all lie in the plane through P_0 normal to (∇f) .

IT ROOKIEE NPTEL ONLINE CERTIFICATION COURSE 3

Gradient of f is orthogonal to the curve's velocity vector if we consider all the curves it passes through a fixed point p hence all the velocity vector at p are

orthogonal to gradient of f at p naught. So, the curves tangent lines all line the plane through p naught is normal to gradient of f ok.

So, what gradient of f gives at a point on the surface gradient of f simply gives a vector normal to a surface now suppose you want to find out a tangent plane at a point x naught y naught z naught. So, how will you find now you have a surface you have a some surface $f(x, y, z)$ is equal to c and at some point x naught y naught z naught you want to find out a tangent plane now the tangent plane we know that gradient of f at a point x naught y naught z naught is normal to a surface. So, it will be a normal to a tangent plane also. So, direction ratios of the normal to at I mean direction ratios of normal to a tangent plane are $\frac{\partial f}{\partial x}$ $\frac{\partial f}{\partial y}$ $\frac{\partial f}{\partial z}$ at p naught $\frac{\partial f}{\partial x}$ $\frac{\partial f}{\partial y}$ $\frac{\partial f}{\partial z}$ at p naught and $\frac{\partial f}{\partial z}$ at p naught ok.

Now, suppose you want to find out a normal line at a point x naught y naught z naught now this is a surface and you want to find out a normal line. Now gradient of f is normal to a surface at p naught. So, gradient of f is also normal and normal line is also perpendicular to the surface at that point. So, gradient of f will be parallel to I mean I mean normal line will be parallel to gradient of f at p naught now how can. So, these are geometrical representation if we have a surface this ok.

(Refer Slide Time: 08:25)

This is a tangent plane.

(Refer Slide Time: 08:30)

Continued...

Tangent plane to $f(x, y, z) = c$ at $P_0(x_0, y_0, z_0)$

$$f_x(P_0)(x - x_0) + f_y(P_0)(y - y_0) + f_z(P_0)(z - z_0) = 0.$$

Normal line to $f(x, y, z) = c$ at $P_0(x_0, y_0, z_0)$

$$x = x_0 + f_x(P_0)t, \quad y = y_0 + f_y(P_0)t, \quad z = z_0 + f_z(P_0)t, \quad t \in \mathbb{R}.$$

 IIT ROORKEE
  NPTEL ONLINE CERTIFICATION COURSE

6

So, gradient of f will be a vector normal to a surface. Now how can you find the equation of tangent plane and a normal line?

(Refer Slide Time: 08:36)

Direction Ratios of $\vec{PP_0}$

$$= ((x - x_0), (y - y_0), (z - z_0))$$

$$\vec{PP_0} = (x - x_0)\hat{i} + (y - y_0)\hat{j} + (z - z_0)\hat{k}$$

$$\vec{PP_0} \perp (\nabla f)_{P_0}$$

$$\Rightarrow f_x(P_0)(x - x_0) + f_y(P_0)(y - y_0) + f_z(P_0)(z - z_0) = 0.$$

$$(\nabla f)_{P_0} = f_x(P_0)\hat{i} + f_y(P_0)\hat{j} + f_z(P_0)\hat{k}$$

Now, suppose this is a surface at some point p which is x naught y naught z naught you are interested to find out the equation of tangent plane the equation of tangent plane at this at this point p now gradient of f will be normal to this point gradient of f at p naught at p gradient of f at. So, we are calling this point as p naught. So, it is p naught ok. So, gradient of f at p naught will be a vector normal to a surface at p naught ok.

Now, let us take an arbitrary point on this plane say this point is $x_1 y_1 z_1$ point let us take an arbitrary point $x_2 y_2 z_2$ on the plane p on the plane on a tangent plane. So, what will be the direction what will be the direction ratios of this vector what will be the direction ratios of this vector? So, direction ratios direction ratios of $\vec{p_1 p_2}$ will be $x_2 - x_1$ $y_2 - y_1$ and $z_2 - z_1$ this will direction ratios of this vector this is $x_2 - x_1$ $y_2 - y_1$ $z_2 - z_1$.

What is gradient of f at p_1 ? This will be f_x at p_1 $\hat{i}$ cap plus f_y at p_1 $\hat{j}$ cap plus f_z at p_1 $\hat{k}$ cap ok. Now what this $\vec{p_1 p_2}$ will be $x_2 - x_1$ $\hat{i}$ cap plus $y_2 - y_1$ $\hat{j}$ cap plus $z_2 - z_1$ $\hat{k}$ cap. Now since gradient of f at p_1 is perpendicular to this line, you see you have a tangent plane you have a tangent plane like this ok. On this surface you have a tangent plane and you have taken arbitrary point on tangent plane and this is $x_1 y_1 z_1$ is a fixed point on the plane.

So, this vector this $\vec{p_1 p_2}$ will lie on the tangent plane and gradient of f is normal to the plane. So, gradient of f will also be normal to $\vec{p_1 p_2}$ to the vector $\vec{p_1 p_2}$. So, we can easily say that $\vec{p_1 p_2}$ vector will be perpendicular to gradient of f at p_1 . So, this implies f_x at p_1 into $x_2 - x_1$ plus f_y at p_1 into $y_2 - y_1$ plus f_z at p_1 into $z_2 - z_1$ will be 0 and this would be the equation of tangent plane at p_1 .

So, if you if you are interested to find out the equation of tangent plane at a point p_1 on the surface $f(x, y, z) = c$. So, we can simply apply this equation to find out the equation of the tangent plane now let us think about normal line. Now if we want to find out the equation of normal line on the surface on the surface.

(Refer Slide Time: 12:18)

If x, y, z is equal to c at a point p_0 which is x_0, y_0, z_0 , we want to find out the equation of the normal line. So, you have this surface. Now this is p_0 which is a fixed point on the surface and you want to find out the equation of the normal line. So, take an arbitrary point on the normal line, take an arbitrary point on the normal line x, y, z say p , p may be any point on the normal line.

So, again what will be the vector $\vec{pp_0}$? The vector $\vec{pp_0}$ will be x minus x_0 $\hat{i}$ plus y minus y_0 $\hat{j}$ plus z minus z_0 $\hat{k}$. Now this vector is on the normal line, normal to a surface, and the gradient of f is also normal to a surface at p_0 . So, both vectors are normal to a surface; that means, both are parallel. So, we can simply say that $\vec{pp_0}$ vector will be parallel to the gradient of f at p_0 . Now since they are parallel, this means they have the same ratios. The ratios will be the same; that means, x minus x_0 upon f_x at p_0 will be the same as y minus y_0 upon f_y at p_0 and z minus z_0 upon f_z at p_0 because this vector is parallel to this vector.

Now, if 2 vectors are parallel, this means one will be λ times the other vector. If this vector is parallel to this vector, this means this vector is λ times the other vector. Now this vector is x minus x_0 $\hat{i}$ plus y minus y_0 $\hat{j}$ plus z minus z_0 $\hat{k}$ will be equal to λ times the gradient of f at p_0 , which is f_x at p_0 $\hat{i}$ plus f_y at p_0 $\hat{j}$ plus f_z at p_0 $\hat{k}$.

So, from here if we equate the coefficients; so, x minus x naught upon f_x at p naught will be equals to y minus y naught upon f_y at p naught will be equals to z minus z naught upon f_z at p naught and that will be equals to λ . So, the same equation is here ok. So, in this way we can easily find out equation of normal line. So, that will be normal line you can take t or λ it hardly matters because a parameter.

(Refer Slide Time: 15:29)

Problems

Find equations for the tangent plane and normal line at the point P_0 on the given surface

1. $x^2 - 4y^2 + 3z^2 + 4 = 0$ at $P_0(3, 2, 1)$
2. $\cos \pi x - x^2 y + e^{xz} + yz = 4$ at $P_0(0, 1, 2)$.

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 7

So, these are some problem let a try let us try to solve these problems.

(Refer Slide Time: 15:35)

$f = x^2 - 4y^2 + 3z^2 + 4 = 0$ $P_0(3, 2, 1)$
 $f_x = 2x$, $f_x|_{P_0} = 6$
 $f_y = -8y$, $f_y|_{P_0} = -16$
 $f_z = 6z$, $f_z|_{P_0} = 6$

Eqⁿ of Tangent plane at P_0 :

$$f_x(P_0)(x - x_0) + f_y(P_0)(y - y_0) + f_z(P_0)(z - z_0) = 0$$

$$6(x - 3) + (-16)(y - 2) + 6(z - 1) = 0$$

$$\Rightarrow 3(x - 3) - 8(y - 2) + 3(z - 1) = 0$$

$$3x - 8y + 3z + 4 = 0$$

Normal line:

$$\frac{x - 3}{6} = \frac{y - 2}{-16} = \frac{z - 1}{6} = t$$

$$x = 3 + 6t, \quad y = 2 - 16t, \quad z = 1 + 6t, \quad t \in \mathbb{R}$$

The first problem is $x^2 - 4y^2 + 3z^2 = 4$ and the point P is $(3, 2, 1)$ ok. So, this is basically f . Now you have to find out the equation of tangent plane a normal line at a point P ok. So, first we will find ∇f by ∇f by ∇x , it is $2x$ and ∇f by ∇y at P will be $-8y$. So, ∇f at P will be simply 6 ∇f by ∇z is $6z$ and ∇f at P will be 6 . So, what will be the equation of tangent line at P it will be equation of tangent line at P will be it is f_x at P $(x - x_P) + f_y$ at P $(y - y_P) + f_z$ at P $(z - z_P) = 0$.

To remember this equation you have to simply remember that the gradient of f is always normal to the plane i mean normal to a surface at a point P . So, if it is normal to a surface at a P . So, if you take a vector $x - x_P$ $y - y_P$ $z - z_P$ on the tangent plane. So, both are perpendicular; that means, dot product will be 0. So, if you take the dot product you will simply get back to this equation what is f_x f_x is $2x$ which is 6 $-8y$ which is -16 and $6z$ which is 6 yeah tangent plane; so, equation of tangent plane ok.

Now, what is f_x at P is 6 $x - x_P$ is 3 it is x_P y_P z_P f_y is -16 $y - y_P$ plus f_z is 6 and $z - z_P$ equal to 0, you divide the entire equation by 2 which is $3x - 3 - 8y - 2 + 3z - 1 = 0$ it is $3x - 8y + 3z = 6$.

Student: Plus 16.

Yeah, it is plus 16 ok. So, it is plus 16. So, it is $-12 + 16 = 4 = 0$. So, this will be the equation of a tangent plane now how can you find the normal line. So, normal line will be $x - x_P$ upon f_x $y - y_P$ upon f_y at P and $z - z_P$ upon f_z will be equals to t . So, x will be given as $3 + 6t$ y is equals to $2 - 16t$ and z equal to $1 + 6t$ where t is any real value ok. So, this is a normal a line now for the second problem.

(Refer Slide Time: 19:35)

$$\begin{aligned}
 f &= \cos \pi x - x^2 y + e^{xz} + yz = 4 \quad p_0(0, 1, 2) \\
 f_x &= -\pi \sin \pi x - 2xy + z e^{xz} \quad f_x|_{p_0} = 2 \\
 f_y &= -x^2 + z \quad f_y|_{p_0} = 2 \\
 f_z &= x e^{xz} + y \quad f_z|_{p_0} = 1 \\
 \text{Tangent plane at } p_0: & \quad 2(x-0) + 2(y-1) + 1(z-2) = 0 \\
 & \Rightarrow 2x + 2y + z = 4. \\
 \text{Normal line at } p_0: & \quad \frac{x-0}{2} = \frac{y-1}{2} = \frac{z-2}{1} = t \\
 & \quad x=2t, y=1+2t, z=1+2t, t \in \mathbb{R}.
 \end{aligned}$$

So, what is f here for a second problem it is $\cos \pi x$ minus it is x square y plus e raise to power xz plus yz is equal to 4 and the point is 0 one 2. So, first we will find f_x what will be f_x f_x is minus $\pi \sin \pi x$ minus $2xy$ plus z times e raise to power xz and f_x at point p naught will be when you substitute x as 0 y as 1 and z as 2. So, this is 0 this is 0 and this will be one and z is 2. So, it is 2.

Now, what is f_y f_y will be a minus x square plus z and f_y at p naught will be x is 0 and z is 2. So, it is again 2. Now f_z f_z is $x e$ raise to power xz plus y and x is 0 and y is one. So, f_z at p naught is one. So, equation of tangent plane will be at p naught will be, it will be 0 into x minus x one it will be f_x f_x at p naught that is 2 2 x minus 0 plus 2 y minus one plus 1 z minus 2 equal to 0.

So, this equation will be simply $2x$ plus $2y$ plus z and it is minus 2 minus 2 that is equal to 4 and equation of normal line at p naught normal line at p naught will be it will be x minus 0 upon 2 y minus 1 upon 2 and z minus 2 upon 1, let us suppose equal to t . So, x will be $2t$ y equals to $1 + 2t$ and z equals to $1 + 2t$ where t is any real number. So, this will be equation of tangent plane and normal line.

Now, if we have a equation or surface like z equals to $f(x, y)$, ok.

(Refer Slide Time: 22:19)

Plane tangent to a surface

The plane tangent to the surface $z = f(x, y)$ of a differentiable function f at the point $P_0(x_0, y_0, z_0) = (x_0, y_0, f(x_0, y_0))$ is

$$f_x(x_0, y_0)(x - x_0) + f_y(y - y_0) - (z - z_0) = 0.$$

Normal line at $P_0 = (x_0, y_0, f(x_0, y_0))$

$$x = x_0 + f_x(x_0, y_0)t, y = y_0 + f_y(x_0, y_0)t, z = z_0 - t, t \in \mathbb{R}.$$

 IIT ROORKEE
  NPTEL ONLINE CERTIFICATION COURSE

8

If we have the equation surface like z equals to $f(x, y)$.

(Refer Slide Time: 22:24)

$z = f(x, y)$
 $f(x, y, z) = f(x, y) - z = 0.$
 Tangent plane at $P_0(x_0, y_0, z_0)$:
 $f_x(P_0)(x - x_0) + f_y(P_0)(y - y_0) + f_z(P_0)(z - z_0) = 0.$
 $\Rightarrow f_x(P_0)(x - x_0) + f_y(P_0)(y - y_0) - (z - z_0) = 0.$
 Normal line at $P_0(x_0, y_0, z_0)$:
 $\frac{x - x_0}{f_x(P_0)} = \frac{y - y_0}{f_y(P_0)} = \frac{z - z_0}{f_z(P_0)} \Rightarrow \frac{x - x_0}{f_x(P_0)} = \frac{y - y_0}{f_y(P_0)} = \frac{z - z_0}{-1} = t$
 $x = x_0 + t f_x(P_0), y = y_0 + t f_y(P_0)$
 $z = z_0 - t,$

So, so take all the things on the one side. So, what will be capital $F(x, y, z)$ it will be $f(x, y)$ minus z equal to 0 and suppose at a point P_0 which is x_0, y_0 and z_0 , you want to find out equation of tangent plane and normal line. So, what will be the equation of tangent plane a normal line for this curve. So, basically this is a special case of the first part.

So, this will be f_x at p naught x minus x naught this will be f_y at p naught y minus y naught plus f_z at p naught z minus z naught equal to 0. So, what is f_x at p naught from this equation it will be f_x small f at if small f_x at p naught x minus x naught plus small y f_y at p naught into y minus y naught and what will be f_z at p naught it is minus 1 always. So, it is z minus z naught equal to 0.

And similarly the equation of normal line at p naught which is x naught y naught z naught will be x minus x naught upon f_x at p naught y minus y naught upon f_y at p naught and z minus z naught upon f_z at p naught. So, this implies this is x minus x naught and f_x at p naught is a small f a small f_x at p naught, this is y minus y naught and similarly it is f_y at p naught and it is z minus z naught upon minus one and say it is t f_z is minus one. So, x will be x naught plus t times f_x at p naught y will be y naught plus t times f_y at p naught and what will be z z will be z naught minus t where t is any real number. So, this will be equation of tangent plane and a normal line at a point p naught for this surface.

(Refer Slide Time: 25:10)

Problems

Find equations for the plane tangent and normal line to the given surface

- 1 $z = e^{-(x^2+y^2)}$, at $(0, 0, 1)$,
- 2 $z = x \cos y - ye^x$ at $(0, 0, 0)$.

IIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 9

Suppose you want to solve this problem find the equations of tangent plane a normal line to the given surface, say we take the first problem similarly we can solve the second problem also.

(Refer Slide Time: 25:18)

$$z = e^{-(x^2+y^2)} \quad p_0(0, 0, 1)$$

$$f_x = -2x e^{-(x^2+y^2)} \quad f_x|_{p_0} = 0$$

$$f_y = -2y e^{-(x^2+y^2)} \quad f_y|_{p_0} = 0$$

Tangent plane at p_0 :

$$0(x-0) + 0(y-0) - 1(z-1) = 0 \Rightarrow z=1$$

Normal line at p_0 :

$$\frac{x-0}{0} = \frac{y-0}{0} = \frac{z-1}{-1} = t$$

$$z = -t + 1$$

So, it is z is equals to e raise to power minus x square plus y square and the point is $0\ 0\ 0$ $0\ 0\ 1$. So, how can we solve this? So, tangent plane will be say tangent plane at p naught will be. So, you first find f_x . So,; so, f_x simply this function ok. So, that will be minus $2x$ e raise to power minus x square minus y square and at $0\ 0\ 1$ it is 0 and f_y will be again minus $2y$ e raise to power minus x square minus y square and f_y at p naught will again be 0 .

So, the equation of tangent plane will be 0 into x minus x naught plus 0 into y minus y naught minus 1 into z minus $z\ 1$ z naught. So, this implies z equals to 1 . So, these are equation of tangent plane at this point for this curve and normal line normal line at p naught will be x minus 0 upon 0 y minus 0 upon 0 and z minus 1 upon minus 1 equal to t . So, you can take this will be z is equals to minus t plus 1 for any for any t , similarly we can solve the next problem.

Now, how to find tangent line to the curve intersection of surfaces ok? Now let us discuss this thing.

(Refer Slide Time: 27:08)

Problems

Find parametric equations for the line tangent to the curve of intersection of the surfaces

- 1 Surfaces: $xyz = 1$, $x^2 + 2y^2 + 3z^2 = 6$, at $(1, 1, 1)$.
- 2 Surfaces: $x^3 + 3x^2y^2 + y^3 + 4xy - z^2 = 0$, $x^2 + y^2 + z^2 = 11$ at $(1, 1, 3)$.

Now suppose you have 2 surfaces, ok, suppose you have 2 surfaces.

(Refer Slide Time: 27:13)

This is one surface and this is second surface this is f equal to c and this is g equal to some k and this is the point of intersection at this point of intersection, you are interested to find out the equation of tangent line, it will be some tangent line because 2 surfaces are intersecting each other. So, it will give a tangent it will give a tangent line now how to find the equation of tangent line at this point.

Now, gradient of f suppose this point is p_0 at p_0 will give will give a vector normal to the surface at p_0 ok. So, it will be definitely normal to a tangent line also similarly gradient of t at p_0 will give a vector normal to the surface g equal to k at p_0 . So, it will be perpendicular to or it will be normal to tangent line also. So, this is also normal to tangent line at p_0 and this is also normal to tangent line at p_0 now the cross product of these 2 vector will give a vector normal to I mean when you are having 2 vector a and b cross product of this give a vector normal to both a and b ok.

So, cross product of these 2 will give a vector normal to both the vectors normal to this vector and this vector and hence nor and hence when it is normal to this and normal to this. So, parallel to this because these 2 because these 2 are normal to this tangent line is it clear because this is normal vector normal to f at p_0 to. So, normal to tangent plane also similarly this is also normal to a tangent at p_0 and the cross product give a vector normal to both the vector this and this. So, the vector which is obtained by the cross product these 2 vector will be parallel to a tangent line ok.

So, in this way we can get the equation of tangent line say v is the vector which is cross product of these 2 vector and say this say this vector is $v_1 \hat{i} + v_2 \hat{j} + v_3 \hat{k}$. So, what will be the equation of tangent line at p_0 will be $x - x_0$ upon v_1 $y - y_0$ upon v_2 and $z - z_0$ upon v_3 because both are parallel you see $x - x_0$ $y - y_0$ $z - z_0$ is a vector lie on the tangent line and vector v is also parallel to tangent line. So, both will parallel this means ratios will be same. So, in this way we can find out the equation of tangent line when 2 curves are intersecting.

Say we have first problem so.

(Refer Slide Time: 30:50)

$$f = xyz = 1, \quad g = x^2 + 3y^2 + 6z^2 = 6 \quad p_0 (1, 1, 1)$$

$$f_x = yz \quad f_x|_{p_0} = 1 \quad f_y|_{p_0} = 1 \quad f_z|_{p_0} = 1$$

$$g_x = 2x \quad g_x|_{p_0} = 2 \quad g_y = 6y \quad g_y|_{p_0} = 6 \quad g_z = 12z \quad g_z|_{p_0} = 12$$

$$v = \begin{vmatrix} \hat{i} & \hat{j} & \hat{k} \\ 1 & 1 & 1 \\ 2 & 6 & 12 \end{vmatrix} = v_1 \hat{i} + v_2 \hat{j} + v_3 \hat{k}$$

$$\frac{x-1}{v_1} = \frac{y-1}{v_2} = \frac{z-1}{v_3} = t$$

Here $f = xyz = 1$ and $g = x^2 + 3y^2 + 6z^2 = 6$ and the point is $(1, 1, 1)$. So, what will be f_x it is yz f_x at p_0 is 1. Similarly f_y at p_0 is 1 and similarly f_z at p_0 is 1 what is g_x g_x will be $2x$ g_x at p_0 will be 2 g_y will be $6y$ and g_z will be $12z$. So, g_x at p_0 will be 2 g_y at p_0 will be 6 and g_z at p_0 will be 12 ok.

So, how to find v , now v will be equals to cross product of these 2 vectors that is $\hat{i}$ cap $\hat{j}$ cap $\hat{k}$ this is $\begin{vmatrix} \hat{i} & \hat{j} & \hat{k} \\ 1 & 1 & 1 \\ 2 & 6 & 12 \end{vmatrix}$ this is $2\hat{i} - 6\hat{j} + 12\hat{k}$ the cross product of gradient of f at p_0 and gradient of g at p_0 this will be v . So, this vector will be the suppose this vector is $v_1 \hat{i} + v_2 \hat{j} + v_3 \hat{k}$ that we can easily find ok, then the equation of tangent line will be $x - 1$ upon v_1 $y - 1$ upon v_2 and $z - 1$ upon v_3 which is t say. So, this will be equation of tangent line at p_0 . So, similarly we can solve the second part also. So, these can also be solved using the properties of tangent plane and normal line these problems so.

Thank you very much.
