Lecture - 14
Extreme Values-I

Hello friends. Welcome to lecture series on multivariable calculus. So, today we will discuss on extremum values; that is, how to find maximum or minimum values of a function of several variables. So, let us first recall with a function of single variable.

(Refer Slide Time: 00:43)

The image shows handwritten mathematical notes on a whiteboard. On the left, the function $f(x) = x^3$ is written, followed by its first derivative $f' = 3x^2$ and the equation $f' = 0 \Rightarrow x = 0$. Below this, the second derivative $f'' = 6x$ is written, and then $f''|_{x=0} = 0$. At the bottom left, $f''' = 6 \neq 0$ is written. On the right, the general case is discussed. It starts with $y = f(x)$ and 'Domain D'. Then, for a point $x=c$, it states $f(x) \leq f(c) \quad \forall x \in D$, which is labeled as 'Absolute maxima'. Similarly, it states $f(x) \geq f(c) \quad \forall x \in D$, which is labeled as 'Absolute minima'.

So, we know that if we have a function say y equals to $f(x)$, a single variable function y equal to $f(x)$. And domain is D supposed of this function. Then a point x equal to c is set to be a point of absolute maxima of this function, if $f(x)$ will be a less than equals to $f(c)$ for every x in D ok.

If this hold, then we say that x equal to c is a point of absolute maxima. Similarly, if $f(x)$ is greater than equals $f(c)$ for every x and D then x equal to c recall as absolute minima. Now how can we check whether points are point of local maxima or local minima? So, we have a second derivative test. So, x equal to a is a point of local maxima, if $f'(a) = 0$ and $f''(a) < 0$. We already know this result ok if a is the point of local maxima, then the first derivative at a will be 0, and second derivative at a will be less than 0.

(Refer Slide Time: 01:49)

Extreme values of function of single variable

- Let $f(x)$ be a function with domain D . Then $f(x)$ has an
 - absolute maximum value on D at a point c if $f(x) \leq f(c) \forall x \in D$ and
 - absolute minimum value on D at c if $f(x) \geq f(c) \forall x \in D$.
- We can locate and identify extreme values of a differential function of a single variable from its derivative
 - $x = a$ is a point of maximum if $f'(a) = 0$ and $f''(a) < 0$
 - $x = a$ is a point of minimum if $f'(a) = 0$ and $f''(a) > 0$

A point where $f''(a) = 0$ and $f'''(a) \neq 0$ is called a point of inflection.

HY ROORKEE NPTEL ONLINE CERTIFICATION COURSE 2

We are assuming that the function is differentiable. x equal to a is a point of local minima if $f'(a) = 0$, and $f''(a) > 0$. A point where $f'(a) = 0$, and $f''(a) = 0$, and $f'''(a) \neq 0$ is called point of inflection ok. Say we have this example $f(x) = x^3$. So, when we take first derivative it is $3x^2$, and $f'(x) = 0$ implies $x = 0$. So, $x = 0$ is a critical point basically.

Now, to check whether this point is the point of maxima minima or point inflection, we find second derivative. Now second derivative is $6x$, and second derivative at $x = 0$ is again 0. Find third derivative third derivative is 6, which is not equal to 0 at $x = 0$. So, this means this point $x = 0$ is the point of inflection.

(Refer Slide Time: 03:24)

Handwritten notes on a whiteboard:

$$Z = f(x, y).$$

$(a, b) \rightarrow$ local maxima
if $f(x, y) \leq f(a, b)$ for all (x, y) in some open disc centered at (a, b)

$(a, b) \rightarrow$ local minima
if $f(x, y) \geq f(a, b)$ for all (x, y) in some open disc centered at (a, b)

Now, let us come to maxima minima of 2 variable functions. Say you have a function of 2 variable ok. So, a point a comma b will be a point of local maxima, will be a point of local maxima if f of x y will be less than equals to f of a b , for some disc for all x y yeah, for all x y in some disc centered at a comma b ok.

You take a point a comma b and there exists a disc. So, centered a comma b , and if for all x y belongs to that disc f x y is less than equal to f a b , then we say that a comma b is a point of local maxima. Similarly, this a b is a point of local minima if f x y is greater than equals to f a b for all x y in some open disc centered at a comma b . It must be open disc. So, if this if this inequality hold for every x y in some open disc centered at a comma b , then we say that a comma b is a point of local minima ok.

So, we first have first derivative test. What is the first derivative test for local extremum values?

(Refer Slide Time: 05:31)

First derivative test for local extreme values

If $f(x, y)$ has a local maximum or minimum value at an interior point (a, b) of its domain and if the first partial derivatives exist there, then $f_x(a, b) = 0$ and $f_y(a, b) = 0$.

BY ROOINKEE NPTEL ONLINE CERTIFICATION COURSE 4

So, if $f(x, y)$ has a local maxima or minimum value, at an interior point a comma b of its domain, and if the first partial derivative exist there, then f_x at a comma b will be 0 ok. Like in the single variable function, a function is differentiable, and x equal to a is a point of local maxima or local minima then f' at a will be 0 ok. In a similar way, here for the 2 variable function if the function at a point a comma b ; which is interior point is a point of local maxima local minima, and its first order partial derivative exist at this point, then f_x at a comma b is equal to 0 and f_y at a comma b is also equal to 0.

(Refer Slide Time: 06:29)

Critical point

An interior point of the domain of a function $f(x, y)$ where both f_x and f_y are zero, or where one or both of f_x and f_y do not exist is a **critical point** of f .

Saddle point

A differentiable function $f(x, y)$ has a saddle point at a critical point (a, b) if in every open disc centered at (a, b) there are domain points (x, y) where $f(x, y) > f(a, b)$ and domain points (x, y) where $f(x, y) < f(a, b)$. The corresponding point $(a, b, f(a, b))$ on the surface $z = f(x, y)$ is called a **saddle point** of the surface.

For example: The point $(0, 0)$ is a saddle point for the function $f(x, y) = y^2 - x^2$.

BY ROOINKEE NPTEL ONLINE CERTIFICATION COURSE 5

Now, what is critical point, and interior point of the domain of the function $f(x, y)$, we are both f_x and f_y are 0, or we are one or both of f_x or f_y do not exist is called the critical point. So, basically critical points of point, where either f_x equal to f_y equal to 0, or f_x or f_y do not exist. Now next is saddle point. A differentiable function $f(x, y)$ has a saddle point at a critical point a, b , if in every open disc centered at a, b there are points x, y where $f(x, y)$ is greater than $f(a, b)$ and x, y , where $f(x, y)$ is less than $f(a, b)$. This point is called saddle point of the surface.

So, in order to understand saddle point, let us discuss this example. So, $f(x, y)$ is suppose y^2 minus x^2 .

(Refer Slide Time: 07:29)

Handwritten notes on a slide showing the analysis of the function $f(x, y) = y^2 - x^2$:

- Function: $f(x, y) = y^2 - x^2$
- Partial derivatives: $f_x = -2x$, $f_y = 2y$
- Critical point condition: $f_x = f_y = 0 \Rightarrow x = y = 0$
- Conclusion: $(0, 0)$ is only critical point.
- Verification of saddle point:
 - $f(x, 0) = -x^2 < f(0, 0) = 0$
 - $f(0, y) = y^2 > f(0, 0) = 0$
- Graph: A coordinate system showing a hyperbola $y^2 - x^2 = 1$ centered at the origin, illustrating the saddle point nature of the origin.
- Additional note: $f_x = f_y = 0$ or both f_x, f_y do not exist.

So, first of all saddle point is a critical point. So, first you find the critical point of this function. For critical point we have 3 conditions ok. We have either f_x equal to f_y equal to 0, or f_x or f_y or both do not exist. So, the point where these 2 result these 2 conditions hold this or this condition hold, we say that point as critical point. Now how to find the critical point of this function is clearly differentiable? So, you can find the f_x as minus $2x$ and f_y as $2y$, and f_x equal to f_y equal to 0 implies x equal to y equal to 0. So, the point is $0, 0$ is the only critical point.

Now, this point is a critical point ok. Now if you take $0, 0$, and take any neighborhood of $0, 0$, I mean any open disc centered at $0, 0$ any open disc. If you take any open disc centered at $0, 0$. So, there are some point

which are on the x axis, and there are always some point which are on the y axis ok. So, f at x comma 0 will be for this function will be minus x square which is always less than $f(0,0)$, which is 0 ok. There are there is always some point on the x axis where the value of the function is less than 0. And if you take on the y axis it is 0 comma y which is y square here, and it is always greater than $f(0,0)$ which is 0.

If you take a point on the y axis, there are some points where the value of the function is greater than 0 ok. No matter which open disc you are taking, whatever for every open disc centered this point they are always some point on the x axis, and they are always some point on the y axis such that at some point this value is less than 0 and some point this values greater than 0. So, this means this point is a saddle point ok.

Now, if you find f_x in f_y ok, after a find the critical points how can we check that a point is a point of local maxima I mean local maxima local minima or saddle point. So, what is the second derivative test for 2 variable functions?

(Refer Slide Time: 10:35)

By Taylor's theorem,

$$(a, b) \rightarrow \text{local maxima or local minima}$$

$$f_x(a, b) = f_y(a, b) = 0 \quad \text{--- (1)}$$

$$f(a+h, b+k) = f(a, b) + f_x(a, b)h + f_y(a, b)k + \frac{1}{2} \left(h^2 f_{xx} + k^2 f_{yy} + 2hk f_{xy} \right) + \dots$$

$$\Rightarrow f(a+h, b+k) - f(a, b) = \frac{1}{2} \left(h^2 f_{xx} + k^2 f_{yy} + 2hk f_{xy} \right) + \dots$$

(a+h, b+k)
 $0 < h, k < 1$

So, let us suppose a comma b is a point of local maxima or local minima. So, if it is a point of local maxima and local minima, and the first and second of partial derivative exist, then f_x at a comma b will be equals to f_y at a comma b will be equals to 0. This is by the first derivative test of local maxima local minima ok.

Now, take a point in the open disc centered at a, b , or take a point say $a + h, b + k$, which is near to a, b . Take a point $a + h, b + k$ which is in the neighborhood of a, b which is in some open disc centered at a, b . You can always find such point in the open disc centered at a, b ok. Now by the Taylor's theorem for 2 variable functions, we know that $f(a + h, b + k)$ will be equals to $f(a, b) + f_x(a, b)h + f_y(a, b)k + \frac{1}{2}(f_{xx}(a, b)h^2 + 2f_{xy}(a, b)hk + f_{yy}(a, b)k^2) + \dots$, where c lies between 0 and 1.

So, this is by the Taylor's theorem of 2 variable functions ok. So, $f(a + h, b + k)$ is equal to this result. Now this is 0, because this point is a point of local maxima and local minima and this is also 0. So, what you obtain from here. So, this implies $f(a + h, b + k) - f(a, b)$ will be equals to $\frac{1}{2}(f_{xx}(a, b)h^2 + 2f_{xy}(a, b)hk + f_{yy}(a, b)k^2) + \dots$ ok. Now to see whether this point is the point of local maxima local minima or saddle point. We have to see the sign of this. If a, b is a point of local maxima suppose ok.

If a, b is a point of local maxima; that means, that means the value of this the value of function at this point will be less than this. Because, because a, b is a point of local maxima ok. So, the value of function at this point will be less than this. So, this value will be less than 0. And hence this must be less than 0. If a, b is a point of local minima, then in the point at the point near to a, b the value of the function will be more than value is a function at a, b . So, the difference will be greater than 0 ok. So, that means, this must be greater than 0 ok. And a saddle point for some h, k , this will be less than 0, and for some other values of h and k this will be less greater than 0, for saddle point.

For saddle point for some h and k because h and k you can vary in that open disc they may be positive and they may be negative for. For those for some h and k this value may be positive and some other values of h and k these values maybe negative for saddle point ok. Hence this values. Now we have to only see the sign of this at this point. So, this will guarantee whether up whether a points of point of local maxima local minima or saddle point.

So, how can we say for this point? I mean this is a function.

(Refer Slide Time: 15:15)

$$Q(h,k) = h^2 f_{xx} + 2hk f_{xy} + k^2 f_{yy}$$

$$(a,b) \rightarrow \text{local maxima}$$

$$\Rightarrow f(a+h, b+k) - f(a,b) > 0$$

$$\Rightarrow A > 0 \text{ and } C A - B^2 > 0$$

$$\Rightarrow f_{xx} > 0 \text{ and } f_{yy} f_{xx} - f_{xy}^2 > 0$$

if $Q(h,k) \neq 0$ then $Q(h,k)$ will have the same sign for sufficiently small values of h and k .

$$Q(h,k) = h^2 f_{xx}(a,b) + 2hk f_{xy}(a,b) + k^2 f_{yy}(a,b)$$

$$Q(h,k) = A h^2 + 2B h k + C k^2$$

$$= A \left[h^2 + \frac{2B}{A} h k \right] + C k^2 \quad A \neq 0$$

$$= A \left[\left(h + \frac{B}{A} k \right)^2 - \frac{B^2}{A^2} k^2 \right] + C k^2$$

$$= A \left(h + \frac{B}{A} k \right)^2 - \frac{B^2}{A} k^2 + C k^2$$

$$= A \left(h + \frac{B}{A} k \right)^2 + \left(\frac{CA - B^2}{A^2} \right) k^2$$

Now, let us let us their this term as say q_c , because it involved c . So, let us call it q_c which is $h^2 f_{xx} + 2hk f_{xy} + k^2 f_{yy}$ at this point. Now if q_c is not equal to 0, then q_c will have the same sign for sufficiently small values of h and k .

If q_c if $Q \neq 0$ if $Q \neq 0$ yeah, $Q \neq 0$ you can say $Q \neq 0$ take say $c \neq 0$. If $Q \neq 0$ is not equal to 0, then this will have the same sign or $Q \neq 0$, you can say $Q \neq 0$ $Q \neq 0$ will have the same sign, for a sufficiently someone values of h and k . You will always take the small values of h and k for which q_c will have the same sign, no matter what, what c you are taking ok. You can take $Q \neq 0$. So, $Q \neq 0$ will be $h^2 f_{xx}$ at a comma b plus $2hk f_{xy}$ at a comma b , plus $k^2 f_{yy}$ at a comma b , because when c is 0 the point will be nothing but a comma b .

Now, we will simply see the sign of this function I mean this value this expression is a sign of this expression is positive. No matter I mean for some small values of h and k ok. If the sign of this expression is positive for small values of h and k , then this means a comma b is a point of local minima if this is negative. This means a comma b is a point of local maxima. So now, let us let us find out the sign of this how can we do this let us see. So, let us suppose this is a h^2 plus $2h k 2 B h k$ plus $C k^2$.

Suppose a is a suppose this is a capital A , suppose this is capital B , and suppose this is capital C . Now make perfect square. You take a common assuming A is not equal to 0. So, this will be h^2 plus $2 B$ by $A h k$ plus $C k^2$. Assuming a is not equal to 0.

So, this implies this is $Ah + B(A^2 + k^2) - B^2(A^2 + k^2) + Ck^2$. Which is further equal to this is $A(Ah + B(A^2 + k^2) - B^2(A^2 + k^2) + Ck^2)$, minus $B^2(A^2 + k^2) + Ck^2$.

So, this will be equal to $Ah + B(A^2 + k^2) - B^2(A^2 + k^2) + Ck^2$. So, if you take a common from the entire expression, if you take a common from the entire expression. So, this will be a square. Now what is what is A ? A is $f''(x)$ at a , B is this value and c is this value.

Now, no matter whatever h and k you are taking in some open disc centered at a , b . If you what if you are calling a, b is a point of is a point of local minima say, if this is a point of local minima then this implies $f(a+h) + k - f(a)$ will be will be greater than 0. Because this is the point of local minima; that means, in the in the point near to a, b the value of the function will be more than this value. So, difference will be positive.

Difference will be positive means this must be positive, because this is equal to this value ok. So, this must be positive. Now this must be positive, for this must be positive no matter what h and k you are taking. So, A , A must be positive. This implies A is positive. And this must be positive. And this implies $f''(x)$ at that point must be positive, and what is c ? C is $f''(y) - f''(x) - f''(x)^2$ must be positive. So, this is the first condition for local minima ok.

Now, if you if you check for local maxima for local maxima if you are calling a, b as a point of local maxima.

(Refer Slide Time: 21:15)

for local maxima (a, b)

$$f(a+h, b+k) - f(a, b) < 0$$

$$\Rightarrow A < 0 \text{ and } cA - B^2 > 0.$$

$(a, b) \rightarrow$ local minima

$$\Rightarrow f(a+h, b+k) - f(a, b) > 0$$

$$\Rightarrow A > 0 \text{ and } cA - B^2 > 0$$

$$\Rightarrow f_{xx} > 0 \text{ and } f_{yy} f_{xx} - f_{xy}^2 > 0.$$

$q(a) = Ah^2 + 2Bhk + ck^2$

$$= A \left[h^2 + \frac{2B}{A}hk \right] + ck^2 \quad A \neq 0$$

$$= A \left[\left(h + \frac{B}{A}k \right)^2 - \frac{B^2}{A^2}k^2 \right] + ck^2 = A \left(h + \frac{B}{A}k \right)^2 - \frac{B^2}{A}k^2 + ck^2$$

$$= A \left(h + \frac{B}{A}k \right)^2 + \left(\frac{cA - B^2}{A} \right) k^2$$

Then f of a plus h plus b plus k minus f of a plus b must be less than 0. And this implies this quantity must be less than 0. For this quantity must be less than 0 what we are having ah ? We are having a must be negative and this must be positive. Because positive plus positive is always positive, and multiplied by negative values always negative. If you take this value as negative value, then for some h and k this maybe positive and for some h and k this maybe negative.

So, we cannot guaranty that whatever h and k we are taking, this will always be negative. So, in order to guaranty this, we take a less than 0 and $cA - B^2$ must be greater than 0. That is the first condition. Now if this value, if this value is negative. Whatever a maybe A may be, positive or negative it hardly matters. If this value is negative, then for some h and k , this minus this, may be negative and for some h and k this and this, this minus this may be positive. So, the in that case it will be a saddle point. Because for some value some for some h and k this is positive, and some for some h and k this is negative. So, a comma b will be a saddle point in that case.

And if it is 0, if it is 0 so, test will be inconclusive. We have to go for the higher order test to find out the nature of a and b ok. So, that is how we can find out whether a point x a b is a point of local maxima local minima or saddle point ok. So, let us discuss first problem based on this.

(Refer Slide Time: 23:24)

$$f(x, y) = xy - x^2 - y^2 - 2x - 2y + 4$$

critical pts:

$$f_x = y - 2x - 2 = 0$$

$$f_y = x - 2y - 2 = 0$$

$$f_x = f_y = 0$$

point $(-2, -2)$

$$f_{xx} = -2$$

$$f_{yy} = -2$$

$$f_{xy} = 1$$

$$f_{xx}|_{(-2, -2)} = -2 < 0$$

$$f_{yy}|_{(-2, -2)} = -2$$

$$f_{xy}|_{(-2, -2)} = 1$$

$$f_{xx} f_{yy} - (f_{xy})^2 = (-2)(-2) - 1^2 = 4 - 1 = 3 > 0$$

So, first problem is, it is xy minus x square minus y square, minus $2x$ minus $4y$ plus 4 , minus $2y$ plus 4 . Now you have to find local maxima local minima and saddle point if exist for the following functions.

So, first find critical points. So, how to find critical points? This function is very nice function this is differentiable. So, you can find f_x , f_x is y minus $2x$ minus 2 equal to 0 . And find f_y f_y is x minus $2y$ minus 2 equal to 0 . You have to find that point where f_x equal to f_y equal to 0 both are 0 . So, that will be a simply point of intersection of these 2 lines, these 2 equations ok. So, what is the point of intersection of these 2 equations? This you can solve so, point will be minus 2 minus 2 you very easily, check you can check also. So, point would be a minus 2 minus 2 yeah it is clear.

Now, we have to check where this point to the point of local maxima local minima or saddle point ok. So, we first find f_{xx} , what is the f_{xx} ? f_{xx} is simply you differentiate partially this again respect to it is a minus 2 . So, f_{xx} at point minus 2 minus 2 is minus 2 it is a negative. Now what is f_{yy} f_{yy} is again minus 2 . So, f_{yy} at this point is minus 2 . And what is f_{xy} ? f_{xy} is 1 . So, f_{xy} at this point is also 1 .

Now, what is what is f_{xx} into f_{yy} minus f_{xy} square, this is equals to this is minus 2 into minus 2 minus 1 . That will be 4 minus 1 it is 3 it is positive. So, f_{xx} is negative, and this value is positive; that means, this point the point of from this result, this point will be a point of local maxima ok.

(Refer Slide Time: 26:12)

$f(x, y) = xy - x^2 - y^2 - 2x - 2y + 4$
 Critical pts: $f_x = y - 2x - 2 = 0$
 $f_y = x - 2y - 2 = 0$
 $f_x = f_y = 0$
 point $(-2, -2)$
 $f_{xx} = -2$ $f_{yy} = -2$ $f_{xy} = 1$
 $f_{xx} f_{yy} - (f_{xy})^2 = (-2)(-2) - 1 = 4 - 1 = 3 > 0$
 $(-2, -2)$ is a pt of local maxima.

So, point minus 2 minus 2 is a point of local maxima ok. Now let us try to solve the second problem.

(Refer Slide Time: 26:29)

$f(x, y) = 4xy - x^4 - y^4$
 $f_x = f_y = 0$
 $f_x = 4y - 4x^3 = 0 \Rightarrow y = x^3$
 $f_y = 4x - 4y^3 = 0 \Rightarrow x = y^3$
 $y = (y^3)^3 = y^9$
 $\Rightarrow y(y^8 - 1) = 0 \Rightarrow y(y^4 - 1)(y^4 + 1) = 0$
 $y(y^2 - 1)(y^2 + 1)(y^4 + 1) = 0$
 $\Rightarrow y = 0, \pm 1$
 $(0, 0), (1, 1), (-1, -1)$

The second problem is $f(x, y)$ is equal to this is $4xy$ minus x raise to power 4 minus y raise to power 4.

So, what is f_x for critical point f_x equal to? f_y equal to 0 so, this implies first you find f_x . What is the f_x ? It is $4y$ minus $4x^3$ which is equal to 0 implies y equal to x^3 . Now f_y f_y is equals to $4x$ minus $4y^3$ equal to 0 implies x equal to y^3 . Now we

have to solve the values of x and y from these 2 equations ok. So, you can substitute x equal to y in this equation. So, what you will obtain y is equals to y cube whole cube, that is y raise to power 9, and this implies y into y raise to power 8 minus 1 will be 0. This implies y y raise to power 4 minus 1 y raise to power 4 plus 1 equal to 0.

Y into y square minus 1 y square plus 1 y raise to the power 4 plus 1 equal to 0, and this implies y equal to 0 or plus minus 1 0 and plus minus 1 no real y here no real y here. So, when y is 0 x is 0. So, points are 0 comma 0, when one it is one, and when minus 1 it is minus 1. So, these are the 3 critical points. Now we have to check which point the point of local maxima minima or saddle point ok.

(Refer Slide Time: 28:21)

$$f(x, y) = 4xy - x^4 - y^4$$

$$f_x = f_y = 0 \quad f_x = 4y - 4x^3 = 0 \Rightarrow y = x^3 \quad f_y = 4x - 4y^3 = 0 \Rightarrow x = y^3$$

$$f_{xx} = -12x^2 \quad f_{xx}|_{(0,0)} = 0 \quad f_{xy} = 4 \quad f_{xy}|_{(0,0)} = 4 \quad f_{yy} = -12y^2 \quad f_{yy}|_{(0,0)} = 0$$

$$f_{xx}f_{yy} - f_{xy}^2 = 0 - 16 < 0$$

$(0, 0) \rightarrow$ Saddle pt.
 $(1, 1)$
 $(-1, -1)$

So, we are having 3 points here 0 0 1 1 and minus 1 minus 1. So, find f_{xx} , what is f_{xx} ? It is minus 12 x square. And f_{xx} at first we check for 0 0 ok. First, we check for 0 0, at 0 0 it is 0 what is f_{xy} ? f_{xy} is 4.

So, f_{xy} at 0 0 is also 4, and what is f_{yy} ? f_{yy} is minus 12 y square which is f_{yy} at 0 comma 0 is 0. So, you find f_{xx} into f_{yy} minus f_{xy} square, if you find f_{xx} for this point, if you find f_{xx} into f_{yy} , minus f_{xy} square. So, this is 0 minus 16, which is less than 0 this implies, this point is a; this point is a saddle point.

(Refer Slide Time: 29:38)

$f(x, y) = 4xy - x^4 - y^4$
 $f_x = f_y = 0$
 $f_x = 4y - 4x^3 = 0 \Rightarrow y = x^3$
 $f_y = 4x - 4y^3 = 0 \Rightarrow x = y^3$
 $f_{xx} = -12x^2$
 $f_{xy} = 4$
 $f_{yy} = -12y^2$
 $f_{xx}|_{(1,1)} = -12$
 $f_{xy}|_{(1,1)} = 4$
 $f_{yy}|_{(1,1)} = -12$
 $f_{xx}f_{yy} - f_{xy}^2 = 0 - 16 < 0$
 $(0, 0) \rightarrow$ Saddle pt.
 $(1, 1) \rightarrow$ local maxima.
 $(-1, -1) \rightarrow$ local maxima.
 $(1, 1) \rightarrow f_{xx} < 0$
 $f_{xx}f_{yy} - f_{xy}^2 = -12 \times -12 - 16 > 0$

Now, check for 1 comma 1. At 1 comma 1 this is minus 12, this remains same, and this value is again minus 12. So, at 1 comma 1, f_{xx} is negative. And what about this value? This value is minus 12 into minus 12 minus 16.

Of course, it is positive. This is negative this is positive that mean this point the point of local maxima. Now again check for minus 1 minus 1. So, what is f_{xx} at minus 1 minus 1? It is remain 12 for minus 1 minus 1 it is again 4.

(Refer Slide Time: 30:30)

$f(x, y) = 4xy - x^4 - y^4$
 $f_x = f_y = 0$
 $f_x = 4y - 4x^3 = 0 \Rightarrow y = x^3$
 $f_y = 4x - 4y^3 = 0 \Rightarrow x = y^3$
 $f_{xx} = -12x^2$
 $f_{xy} = 4$
 $f_{yy} = -12y^2$
 $f_{xx}|_{(1,1)} = -12$
 $f_{xy}|_{(1,1)} = 4$
 $f_{yy}|_{(1,1)} = -12$
 $f_{xx}f_{yy} - f_{xy}^2 = 0 - 16 < 0$
 $(0, 0) \rightarrow$ Saddle pt.
 $(1, 1) \rightarrow$ local maxima.
 $(-1, -1) \rightarrow$ local maxima.
 $(1, 1) \rightarrow f_{xx} < 0$
 $f_{xx}f_{yy} - f_{xy}^2 = -12 \times -12 - 16 > 0$

For minus 1 minus 1 it is minus 12. So, the analysis remains the same, it is negative and $f_{xx}f_{yy} - (f_{xy})^2$ is positive. So, this point is again a point of local maxima. So, in this way we can find out the nature of the points, nature of the critical points. So, similarly we can also solve question number 3 and question number 4 to find out which point the point of local maxima local minima or saddle point.

So, thank you very much.
