Lecture - 22
Change of Variables in Multiple Integral

Hello friends, so welcome to the second lecture of the fifth unit of this course. You know in the last lecture, we have discuss about the change of order in the multiple integral. In this lecture, I will talk about another important concept related to the multiple integral and that is change of variables in multiple integrals. So, let us understand what is; Change of Variable.

(Refer Slide Time: 00:54)

The image shows a whiteboard with handwritten mathematical steps for solving a definite integral using substitution. The steps are as follows:

$$I = \int_{y=0}^1 y^2 e^{y^3} dy$$
$$\text{Let } y^3 = t$$
$$3y^2 dy = dt$$
$$= \frac{1}{3} \int_0^1 e^t dt$$

So, first take a simple example of definite integral. So, suppose, I need to solve this particular integral, so for solving this integral what I need to do I need to make some substitution. Substitution means I need to change the variable y . So, for doing this what I need to do let y cube equals to t ; and from here I will get $3 y$ square dy equals to dt . Since, I am having this y square term here. So, my this integral will become 1 by 3 e raise to power t dt . When y is 0 , t will be 0 ; when y is 1 , t will be 1 .

So, my original problem was in y , but now my variable is t . And if you look at both of these definite integrals, this is looking quite easy when compared to this one. So, we have made the change of variable from y to t by putting y cube equals to t , and then we

have convert our integral in a simple form. So, we have done change of variable in definite integral also.

(Refer Slide Time: 02:41)

Change of variables: Definition

Suppose that we want to integrate $f(x, y)$ over the region R . Under the transformation $x = g(u, v)$, $y = h(u, v)$ the region becomes S and the integral becomes,

$$\iint_R f(x, y) \, dA = \iint_S f(g(u, v), h(u, v)) \left| \frac{\partial(x, y)}{\partial(u, v)} \right| \, du \, dv$$

Note that we used $du \, dv$ instead of dA in the integral to make it clear that we are now integrating with respect to u and v . Also note that we are taking the absolute value of the Jacobian. If we look just at the differentials in the above formula we can also say that

$$dA = \left| \frac{\partial(x, y)}{\partial(u, v)} \right| \, du \, dv$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 5

Now, what we need we need to extend this concept in case of multiple integrals. in multiple integrals, what is change of variables. Suppose, we want to integrate a function f of x, y over the region R ; under the transformation x equals to g of u, v and y equals to h of u, v the region becomes S . Like in case of definite integral our limit change. Here the region of integration will also change when you make the transformations or change of variables.

So, region becomes S and the integral becomes now means our original integral was like this. A double integral over the region R f of $x, y \, dA$ this will convert into the region is now S x will be g of u, v y will be h of u, v . Absolute value of the Jacobian of x, y with respect to u, v into $du \, dv$.

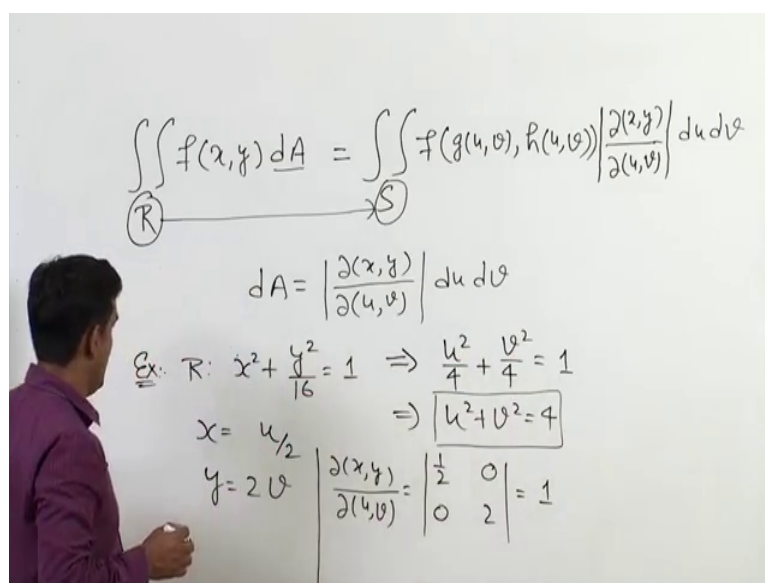

(Refer Slide Time: 03:42)

$$\iint_R f(x, y) dA = \iint_S f(g(u, v), h(u, v)) \left| \frac{\partial(x, y)}{\partial(u, v)} \right| du dv$$
$$x = g(u, v)$$
$$y = h(u, v)$$

So, basically what we are having, we are having $\iint_R f(x, y) dA$. This dA is where be $dx dy$ or $dy dx$, we are not taking the order here mean exact to the write a $dx dy$ or $dy dx$. So, it may be anything which ever will be the simple one. So, now what I am doing I am making a transformation x equals to g of u, v y equals to h of u, v . So, after making these two transformations means my original problem is in variable x and y , I am changing it into the variable u and v . So, after doing this as I told you region will change. And we will see by the examples how region will change.

So, earlier region what R now it will become S f of x will become g of u, v , y will become h of u, v and then this dA ; dA will become absolute value of Jacobian $x y$ up or with respect to u, v , and then $du dv$. So, this is a change of variables in case of double integral similar concept can be extended to the triple integral.

(Refer Slide Time: 05:31)

$$\iint_{\textcircled{R}} f(x, y) dA = \iint_{\textcircled{S}} f(g(u, v), h(u, v)) \left| \frac{\partial(x, y)}{\partial(u, v)} \right| du dv$$
$$dA = \left| \frac{\partial(x, y)}{\partial(u, v)} \right| du dv$$

Ex: $R: x^2 + \frac{y^2}{16} = 1 \Rightarrow \frac{u^2}{4} + \frac{v^2}{4} = 1$

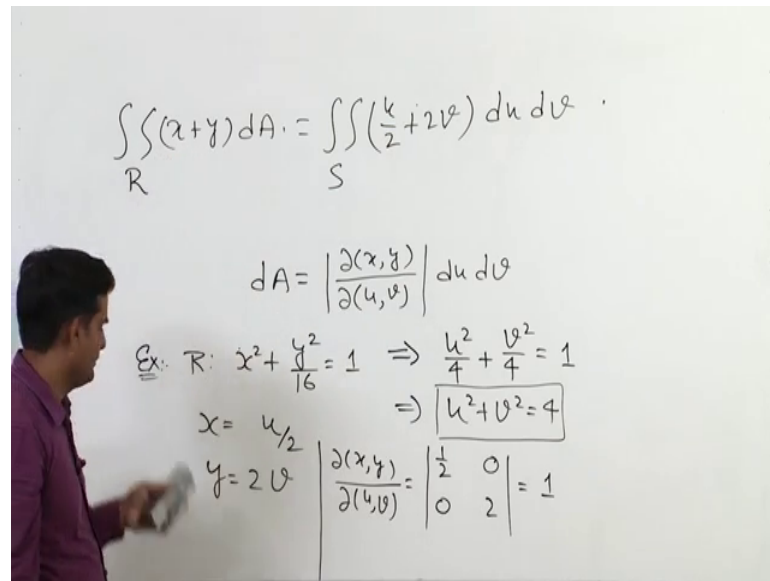

$$\Rightarrow \boxed{u^2 + v^2 = 4}$$
$$\begin{array}{l} x = u/2 \\ y = 2v \end{array} \quad \left| \frac{\partial(x, y)}{\partial(u, v)} \right| = \begin{vmatrix} \frac{1}{2} & 0 \\ 0 & 2 \end{vmatrix} = 1$$

Here you have to notice one is earlier region what R , now it become S . The other thing is this dA is now Jacobian of x, y with respect to u, v $du dv$. And these two things are coming from the region. For example, suppose I am having a region let us say initially I am having region R is an ellipse given by $x^2 + y^2/16 = 1$. So, this is my original region ok.

Let us take I made the transformation x equals to $u/2$, and y equals to $2v$. So, if I apply these two transformations on this region, what will happen, this region will convert x^2 means u^2 upon 4 plus y^2 upon 16, so 1 by 16 into for v^2 so v^2 upon 4 equals to 1. And this comes out is $u^2 + v^2 = 4$. So, my original region was an ellipse, now it becomes a circle. And you know that integration over a circle is quite easy when compared to an ellipse, because there you can convert it into polar coordinates, and you can have constant limit for R as well as for θ .

The other thing which is important to notice here what will be dA in this case so, here first of all to we need to calculate the Jacobian. So, x, y upon $du dv$, so $\partial x / \partial u$ $\partial x / \partial v$ $\partial y / \partial u$ $\partial y / \partial v$ so $\partial x / \partial u$ will become 1 by 2, $\partial x / \partial v$ 0 then $\partial y / \partial u$ which is 0 and $\partial y / \partial v$ that is 2. So, here Jacobian is coming out to be 1. So, hence dA will become simply $du dv$.

(Refer Slide Time: 09:00)

$$\iint_R (x+y) dA = \iint_S \left(\frac{u}{2} + 2v\right) du dv$$
$$dA = \left| \frac{\partial(x,y)}{\partial(u,v)} \right| du dv$$

Ex: $R: x^2 + \frac{y^2}{16} = 1 \Rightarrow \frac{u^2}{4} + \frac{v^2}{4} = 1$
 $\Rightarrow u^2 + v^2 = 4$

$$x = \frac{u}{2}, y = 2v$$
$$\frac{\partial(x,y)}{\partial(u,v)} = \begin{vmatrix} \frac{1}{2} & 0 \\ 0 & 2 \end{vmatrix} = 1$$

So, if I am having a problem on this particular region, for example if I am having an integral R which is let us say x plus y dA , now it will become S . So, R was in ellipse earlier, now this is a circle of radius two having centre at the origin, x plus y will become u by 2 plus 3 v my Jacobian is 1 so $du dv$. So, this is the change of variables which I have explain with the help of this simple example.

Now, there are two regions for changing the variables. The first region is suppose we are having the region of integration it is complicated. So, can we apply some transformation, so that the region will become a simple region where the integration will become easy. The other regions is if we are having complicated function here under the integration on which we have to perform integration. So, by applying the some transformations can we change this particular function into a simple form. So, these are the two regions behind the concept of change of variables.

Now, we will take some example, and I will explain I will take an example where region earlier region will be the complicated, but later on it will become simple and the other one also.

(Refer Slide Time: 10:54)

Change of variables: Example-I

Question
Evaluate $\iint_R (x^2 - xy + y^2) dA$, where R is an ellipse given by $x^2 - xy + y^2 = 2$ and using the transformation $x = \sqrt{2}u - \sqrt{\frac{2}{3}}v$, $y = \sqrt{2}u + \sqrt{\frac{2}{3}}v$

Solution
Here, region $R: x^2 - xy + y^2 = 2$ converts into region $S: u^2 + v^2 = 1$.
Therefore,
$$\iint_R (x^2 - xy + y^2) dA = \iint_S 2(u^2 + v^2) \left| \frac{4}{\sqrt{3}} \right| du dv = \frac{8}{\sqrt{3}} \int_0^{2\pi} \int_0^1 r^2(r) dr d\theta = \frac{4\pi}{\sqrt{3}}$$

VT ROORKEE NPTL ONLINE CERTIFICATION COURSE 7

So, let us take this particular example here we need to evaluate $x^2 - xy + y^2$ over the region R , where R is given by the ellipse $x^2 - xy + y^2 = 2$. So, region under inside this ellipse and on the boundary of this ellipse, and using the transformation x equals to square root 2 into u minus square root 2 by 3 into v , and y equals to square root 2 u plus square root 2 by 3 into v .

(Refer Slide Time: 11:28)

$$Ex: \iint_R (x^2 - xy + y^2) dA$$

$$R: x^2 - xy + y^2 = 2$$

$$x = \sqrt{2}u - \sqrt{\frac{2}{3}}v$$

$$y = \sqrt{2}u + \sqrt{\frac{2}{3}}v$$

$$x^2 - xy + y^2 = 2u^2 + \frac{2}{3}v^2 - 2\sqrt{2}\sqrt{\frac{2}{3}}uv$$

$$- (2u^2 - \frac{2}{3}v^2) + 2u^2 + \frac{2}{3}v^2$$

$$+ 2\sqrt{2}\sqrt{\frac{2}{3}}uv$$

$$= 2u^2 + 2v^2 = 2$$

$$\Rightarrow \boxed{u^2 + v^2 = 1}$$

So, I am having $x^2 - xy + y^2$ over the region R , where R is given by the ellipse $x^2 - xy + y^2 = 2$. The transformation is which I

need to apply x equals to $\sqrt{2}u - \sqrt{2}v$ and y equals to $\sqrt{2}u + \sqrt{2}v$. So, here we are having something some easy thing that this is dA the integral and the region are having same function.

So, let us see after applying these two transformations what will be my new function. So, earlier I am having this one. So, $x^2 - xy + y^2$ will become $2u^2 + 2v^2 - 2\sqrt{2}u\sqrt{2}v$; Then minus x, y , so minus xy will become $2u^2 - 2v^2$ because $a - b$ into $a + b$, so $a^2 - b^2$. And finally, y^2 so plus $2u^2 + 2v^2$ minus and now it will become plus $2\sqrt{2}u\sqrt{2}v$.

So, these two terms are cancel out $2u^2 - 2u^2 + 2u^2$. So, it will become that I should it equals to $2u^2 + 2v^2$ plus $2\sqrt{2}u\sqrt{2}v$ plus $2\sqrt{2}u\sqrt{2}v$ so, $6\sqrt{2}u\sqrt{2}v$, so plus $2v^2$. So, we have taken all the terms, it was equals to 2. So, this equals to 2. So, from here after change of variables, the region becomes a circle of unit radius and having centre at the origin.

(Refer Slide Time: 15:13)

$$\begin{aligned}
 \text{Ex: } & \iint_R (x^2 - xy + y^2) dA \\
 &= \iint_S 2(u^2 + v^2) dS
 \end{aligned}
 \quad \left| \quad
 \begin{aligned}
 x^2 - xy + y^2 &= 2u^2 + \frac{2}{3}v^2 - 2\sqrt{2}\sqrt{2}uv \\
 &= (2u^2 - \frac{2}{3}v^2) + 2u^2 + \frac{2}{3}v^2 \\
 &\quad + 2\sqrt{2}\sqrt{2}uv \\
 &= 2u^2 + 2v^2 = 2 \\
 \Rightarrow & \boxed{u^2 + v^2 = 1} \in S
 \end{aligned}$$

So, now, I can write this integral. So, this will become $2u^2 + 2v^2$ because this term equals to twice u^2 plus twice v^2 ; only thing I need to calculate Jacobian. The limit will become the new region S . Here S is given by the circle of unit radius.

(Refer Slide Time: 15:43)

$$\begin{aligned}
 \underline{E_x} &\rightarrow \iint_R (x^2 - xy + y^2) dA \\
 &= \iint_S 2(u^2 + v^2) \left| \frac{4}{\sqrt{3}} \right| du dv \quad \left| \begin{array}{l} x = \sqrt{2}u - \sqrt{\frac{2}{3}}v \\ y = \sqrt{2}u + \sqrt{\frac{2}{3}}v \end{array} \right. \\
 &\quad S: u^2 + v^2 = 1 \quad \left| \frac{\partial(x,y)}{\partial(u,v)} = \begin{vmatrix} \sqrt{2} & -\sqrt{\frac{2}{3}} \\ \sqrt{2} & \sqrt{\frac{2}{3}} \end{vmatrix} \right. \\
 &\quad \quad \quad = \frac{2}{\sqrt{3}} + \frac{2}{\sqrt{3}} = \frac{4}{\sqrt{3}}
 \end{aligned}$$

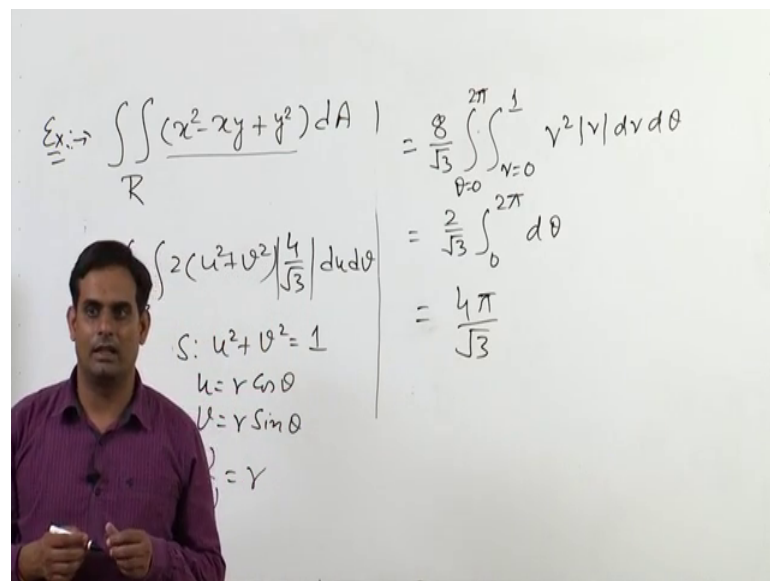

So, now, let me calculate Jacobian. So, x is root 2 u minus root 2 by 3 v and y is root 2 u plus root 2 by 3 v. So, del x y with respect 2 u v del x over del u. So, del x over del u will be root 2 del x over del v del y over del u del y over del v. So, this will become 2 by root 3 because root 2 into root 2 will become 2 upon root 3 plus 2 by root 3 minus minus will become plus so 4 upon root 3. So, 4 upon root 3 absolute value of this into d u d v; and S is given by this particular circle.

(Refer Slide Time: 17:15)

$$\begin{aligned}
 \underline{E_x} &\rightarrow \iint_R (x^2 - xy + y^2) dA = \frac{8}{\sqrt{3}} \int_{\theta=0}^{2\pi} \int_{r=0}^1 r^2 |v| dr d\theta \\
 &= \iint_S 2(u^2 + v^2) \left| \frac{4}{\sqrt{3}} \right| du dv = \frac{2}{\sqrt{3}} \int_0^{2\pi} d\theta \\
 &\quad S: u^2 + v^2 = 1 \\
 &\quad \quad u = r \cos \theta \\
 &\quad \quad v = r \sin \theta \\
 &\quad \quad \frac{\partial(u,v)}{\partial(r,\theta)} = r
 \end{aligned}$$

Now, this integral can be written as $2\sqrt{8}$ upon $\sqrt{3}$ and if I change it into polar coordinates because it is a circle. So, means again change of variable u equals to $r \cos \theta$ v equals to $r \sin \theta$. So, $du dv$ will become here $r dr d\theta$. So, it means $du dv$ will be $r dr d\theta$ it is a circle of unit radius r will go from 0 to 1 and θ will go 0 to 2π $u^2 + v^2$ will become r^2 into $r dr d\theta$, because it will become r^3 r^3 will become r^4 upon 4. So, I have adjusted for here earlier it was 8, now it is 2; r for when you substitute limit when you will put one it will become one when zero it will become 0, so simply θ .

(Refer Slide Time: 18:52)

$$\begin{aligned} \text{Ex: } \iint_R (x^2 - xy + y^2) dA &= \frac{8}{\sqrt{3}} \int_{\theta=0}^{2\pi} \int_{r=0}^1 r^2 |r| dr d\theta \\ &= \frac{2}{\sqrt{3}} \int_0^{2\pi} d\theta \\ &= \frac{4\pi}{\sqrt{3}} \end{aligned}$$

$S: u^2 + v^2 = 1$
 $u = r \cos \theta$
 $v = r \sin \theta$
 $r = 1$

So, basically it will be 4π over $\sqrt{3}$ now take another example.

(Refer Slide Time: 19:01)

Question

Evaluate $\int \int_R (x+y)(x-y) dx dy$ where $R: 1-y \leq x \leq 2-y$, and $0 \leq y \leq 2$

Solution

Using the substitution $u = x + y$ and $v = x - y$, we get the Region R' :
 $u - 4 \leq v \leq u$ and $1 \leq u \leq 2$. Hence the integral becomes

$$\int_1^2 \int_{u-4}^u uv |J| dv du$$

where J is the Jacobian of the transformation calculated as

$$J = \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} \end{vmatrix} = \begin{vmatrix} \frac{1}{2} & \frac{1}{2} \\ \frac{1}{2} & -\frac{1}{2} \end{vmatrix} = -\frac{1}{2}$$

Hence we get the answer as $-\frac{4}{3}$

2

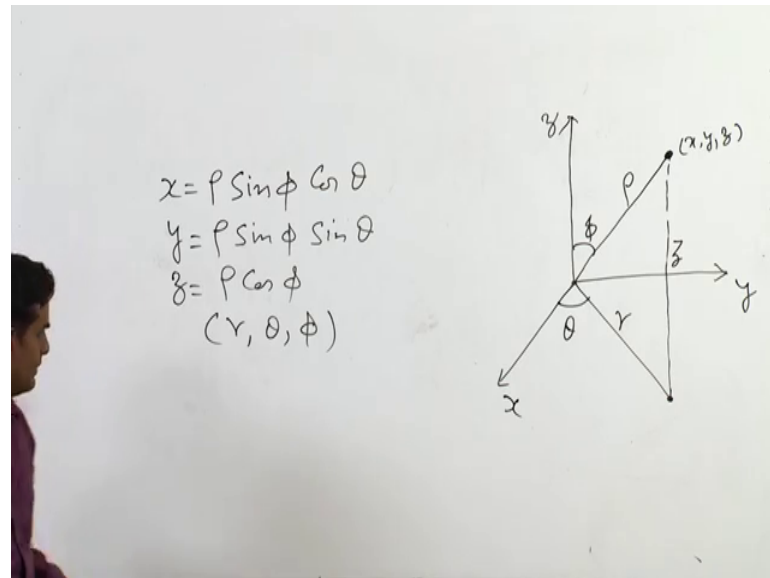

So, in this example, we have to evaluate this particular double integral over a region R . So, here double integral x plus y x minus y $dx dy$, and the region R is given in such a way that x is bounded by $1 - y$ to $2 - y$ and y is between 0 to 2 . So, first of all we cannot evaluate this integral in an easy manner directly in this particular region. So, what we need to do we need make some transformations or change of variables.

So, let us make change of variables using these two transformations that is u equals to x plus y , and v equals to x minus y . If we used these two transformations my region R transform into R' , which is given by v is between $u - 4$ to u and u is between 1 to 2 . Hence, the double integral converts into this particular double integral that is since my x plus y is u x minus y is v . So, u into v then I need to find out the Jacobian and then $dv du$. Here I am writing $dv du$ as you know that I am having constant limits for u . So, I am taking du at the end, I will evaluate it later.

So, when I calculate Jacobian, Jacobian is given in this way $\frac{\partial x}{\partial u} \frac{\partial x}{\partial v} \frac{\partial y}{\partial u} \frac{\partial y}{\partial v}$. So, here $\frac{\partial x}{\partial u}$ becomes $\frac{1}{2}$ because x will be simply become u plus v by 2 , and y will become u minus v by 2 that we are getting from these two transformations. So, $\frac{\partial u}{\partial x}$ sorry $\frac{\partial x}{\partial u}$ is $\frac{1}{2}$ $\frac{\partial x}{\partial v}$ is $\frac{1}{2}$, $\frac{\partial y}{\partial u}$ is $\frac{1}{2}$, and $\frac{\partial y}{\partial v}$ is minus $\frac{1}{2}$. So, when I evaluate these particular integral this will become $\frac{1}{2}$ that is the absolute value of this; otherwise it will come out to be minus $\frac{1}{2}$. And since I have to

take the absolute value, so it is 1 by 2. If I substitute it here it will become 1 by 2 double integral $u \, v \, dv \, du$. So, after evaluating this particular integral, I got the value of this integral h minus 4 by 3.

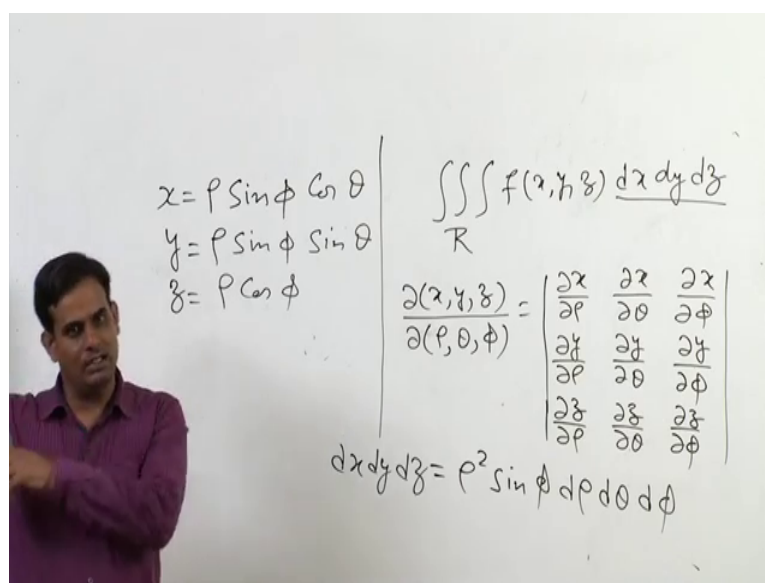

(Refer Slide Time: 22:00)

Now take one more example and that is we take in spherical coordinate. So, as you know that if I am having x, y, z coordinate system; and I am having a point here x, y, z ok. And I want to represent this point. So, this is let us say my x -axis, y -axis and z -axis. So, let me take this angle is ϕ , this distance as ρ . So, what will happen this distance will be z , this angle let us take θ . So, let us take at the said r .

So, what I will be having x equals to ρ , so $\rho \sin \phi \cos \theta$ then y will become $\rho \sin \phi \sin \theta$. So, basically R is $\rho \sin$ here higher project this on to this line and then z will become $\rho \cos \phi$. So, this transformation is called converting from Cartesian coordinates to spherical coordinates. And now my new coordinates is r, θ and ϕ , where ϕ will be between 0 to ϕ .

(Refer Slide Time: 24:16)

The whiteboard contains the following handwritten mathematical content:

$$\begin{aligned}x &= \rho \sin \phi \cos \theta \\y &= \rho \sin \phi \sin \theta \\z &= \rho \cos \phi\end{aligned}$$
$$\iiint_R f(x, y, z) \, dx \, dy \, dz$$
$$\frac{\partial(x, y, z)}{\partial(\rho, \theta, \phi)} = \begin{vmatrix} \frac{\partial x}{\partial \rho} & \frac{\partial x}{\partial \theta} & \frac{\partial x}{\partial \phi} \\ \frac{\partial y}{\partial \rho} & \frac{\partial y}{\partial \theta} & \frac{\partial y}{\partial \phi} \\ \frac{\partial z}{\partial \rho} & \frac{\partial z}{\partial \theta} & \frac{\partial z}{\partial \phi} \end{vmatrix}$$
$$dx \, dy \, dz = \rho^2 \sin \phi \, d\rho \, d\theta \, d\phi$$

Now, if I convert my problem into this that is let us say I am having a triple integral over a region three dimensional region R of x, y, z $dx \, dy \, dz$. So, what dx, dy, dz will be come in this is spherical coordinates after applying these transformation. So, here you I need to calculate $dx \, dy \, dz$ over $d\rho \, d\theta \, d\phi$. So, it will be a Jacobian that is dx over $d\rho$ dx over $d\theta$ dx over $d\phi$ dy over $d\rho$ dy over $d\theta$ dy over $d\phi$, and then dz over $d\rho$ dz over $d\theta$ dz over $d\phi$.

So, if I simplify by this, the Jacobian comes out be $\rho^2 \sin \phi \, d\rho \, d\theta \, d\phi$ and which will be equals to $dx \, dy \, dz$. So, this is the change your variables when you are changing your variables from Cartesian to spherical coordinates that is the extension of polar coordinates into θ and ϕ . Similarly in cylindrical $dx \, dy \, dz$ will become $r \, dr \, d\theta \, dz$ because their coordinates are r, θ and z .

So, in this lecture what we have done we have taken the definition of change of variables. Then we have seen few examples for the region y we do it. After that we have seen how we can convert our triple integral which is given in Cartesian coordinates to the spherical coordinates by using the concept of change of variables.

Thank you.
