Lecture – 33
Some Identities on Divergence and Curl

Hello friends welcome to the 33 lecture of this course. So, this lecture is again in the continuous, is in the continuation of the previous lecture. So, in the previous lecture we have learnt about divergence and curl. In the last lecture we have taken an example like a function ϕ is given to you which is a scalar function and then we need to find out curl of grad ϕ and divergence of grad ϕ .

(Refer Slide Time: 00:53)

Handwritten derivation on a whiteboard:

Left side:

$$\begin{aligned} & \phi \\ & \text{Curl}(\text{grad } \phi) \\ & \vec{\nabla} \times (\vec{\nabla} \phi) \\ & = \vec{\nabla} \times \left(\frac{\partial \phi}{\partial x} \hat{i} + \frac{\partial \phi}{\partial y} \hat{j} + \frac{\partial \phi}{\partial z} \hat{k} \right) \\ & = \begin{vmatrix} \hat{i} & \hat{j} & \hat{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ \frac{\partial \phi}{\partial x} & \frac{\partial \phi}{\partial y} & \frac{\partial \phi}{\partial z} \end{vmatrix} = \vec{0} \end{aligned}$$

Right side:

$$\begin{aligned} & \text{Curl}(\text{grad } \phi) = 0 \\ & \text{A vector field } \vec{V} \text{ is conservative if} \\ & \text{Curl } \vec{V} = 0 \\ & \text{Curl}(\text{grad } \phi) = 0 \end{aligned}$$

So, we have taken an example, a particular example. Now, let us see in general what these things are. So, curl of grad ϕ . So, basically curl of grad ϕ is given as $\nabla \times \nabla \phi$. So, this will be $\nabla \times \nabla \phi$ over $\nabla x i$ plus $\nabla y j$ plus $\nabla z k$. So, this will become $i j k \nabla$ by $\nabla x \nabla y \nabla z$, and then $\nabla \phi$ over $\nabla x j$ component is $\nabla \phi$ over $\nabla y \nabla \phi$ over ∇z .

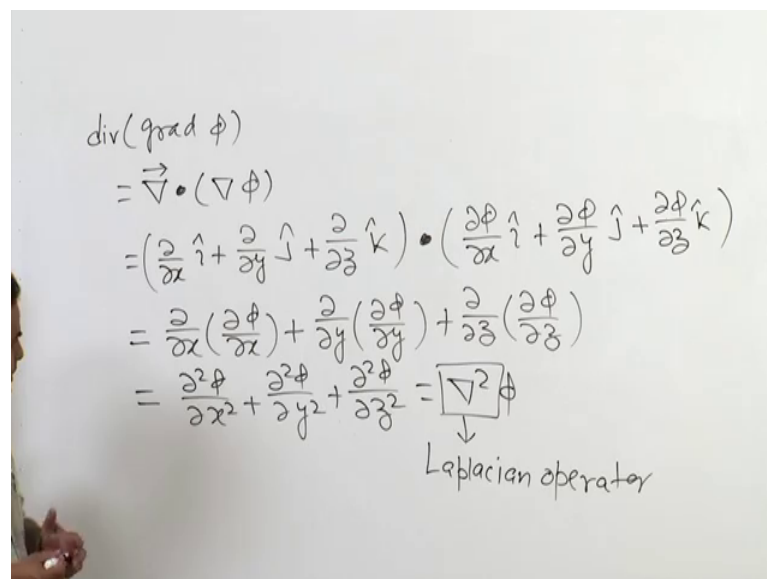

Now if I compute this thing the i component will become $\nabla^2 \phi$ over $\nabla y \nabla z$ minus $\nabla^2 \phi$ over $\nabla y \nabla z$. So, $0 j$ component will become again 0 and k component will be 0 . So, it comes out to be 0 . So, hence in the previous lecture I have directly written it 0 . So, what I want to say that curl of gradient of a scalar function will be always 0 . So, if

curl of grad phi equals to 0, then can we relate it with some other concept. Yes we can relate and what is that concept. That particular concept is about potential function or conservative vector field.

So, a vector field is conservative if or let us say vector field \mathbf{v} curl of \mathbf{v} equals to 0. Why I am writing it, because if \mathbf{v} is conservative then I can write \mathbf{v} as the gradient of a potential function. So, that is basically gradient of phi and curl of gradient of phi. We have just shown that it is always 0. So, this is another way of testing whether a given vector function is conservative or not. Instead of finding the potential function phi what you can do?

You can just calculate the curl of that vector field and if it is 0, then the vector function is conservative. Another thing which we have calculated in the previous lecture was the divergence of grad of phi and this I have calculated for a particular example in the previous class. Now, let us see what is this

(Refer Slide Time: 04:48)

$$\begin{aligned}
 \text{div}(\text{grad } \phi) &= \vec{\nabla} \cdot (\nabla \phi) \\
 &= \left(\frac{\partial}{\partial x} \hat{i} + \frac{\partial}{\partial y} \hat{j} + \frac{\partial}{\partial z} \hat{k} \right) \cdot \left(\frac{\partial \phi}{\partial x} \hat{i} + \frac{\partial \phi}{\partial y} \hat{j} + \frac{\partial \phi}{\partial z} \hat{k} \right) \\
 &= \frac{\partial}{\partial x} \left(\frac{\partial \phi}{\partial x} \right) + \frac{\partial}{\partial y} \left(\frac{\partial \phi}{\partial y} \right) + \frac{\partial}{\partial z} \left(\frac{\partial \phi}{\partial z} \right) \\
 &= \frac{\partial^2 \phi}{\partial x^2} + \frac{\partial^2 \phi}{\partial y^2} + \frac{\partial^2 \phi}{\partial z^2} = \boxed{\nabla^2 \phi} \\
 &\quad \downarrow \\
 &\quad \text{Laplacian operator}
 \end{aligned}$$

This is basically del of vector of dot product with del phi. So, this become del by del x in the direction of y del by del y in the direction of j, del by del z in the direction of k and dot product with del phi over del x in the direction of i plus del phi over z. Sorry del y in the direction of j plus del phi over del z in the direction of k. So, this basically in the second down bracket we are having del phi; that is gradient of phi.

Now, if I do the dot product of these two vectors it will become $\nabla \cdot (\nabla \phi)$ over ∇x plus $\nabla \cdot (\nabla \phi)$ over ∇y plus $\nabla \cdot (\nabla \phi)$ over ∇z and this comes out to be $\nabla^2 \phi$ over ∇x^2 plus $\nabla^2 \phi$ over ∇y^2 plus $\nabla^2 \phi$ over ∇z^2 .

And this I can basically I can denote with this notation this particular operator is called Laplacian operator. So, basically Laplacian operator is ∇^2 over ∇x^2 plus ∇^2 over ∇y^2 plus ∇^2 over ∇z^2 and denoted by this. Now the equation $\nabla^2 \phi = 0$ is called Laplace equation, and it is a famous partial differential equation.

(Refer Slide Time: 07:17)

Can you tell me a function which is satisfied this equation. So, so here we can easily construct such a function. For example, if I take ϕ equals to $x^2 + y^2 - 2z^2$, then $\nabla^2 \phi$ over ∇x^2 plus $\nabla^2 \phi$ over ∇y^2 plus $\nabla^2 \phi$ over ∇z^2 which is basically Laplacian operator operating on ϕ .

So, this term is 2 plus second order partial derivative of this ϕ with respect to y is 2 minus 4 and this comes out to be 0. Hence, this particular scalar function ϕ satisfy the Laplace equation. After this we will take few more identities on divergence and curl. So, with the these two previous properties the next identity is, let me write as i 1.

(Refer Slide Time: 08:49)

If \vec{A} and \vec{B} are two vector functions, then

I 1: $\text{div}(\vec{A} + \vec{B}) = \text{div}(\vec{A}) + \text{div}(\vec{B})$

Proof: $\text{div}(\vec{A} + \vec{B}) = \vec{\nabla} \cdot (\vec{A} + \vec{B})$

$\vec{A} = A_1 \hat{i} + A_2 \hat{j} + A_3 \hat{k}$
 $\vec{B} = B_1 \hat{i} + B_2 \hat{j} + B_3 \hat{k}$
 then
 $\vec{A} + \vec{B} = (A_1 + B_1) \hat{i} + (A_2 + B_2) \hat{j} + (A_3 + B_3) \hat{k}$

$$= \frac{\partial(A_1 + B_1)}{\partial x} + \frac{\partial(A_2 + B_2)}{\partial y} + \frac{\partial(A_3 + B_3)}{\partial z}$$

$$= \left(\frac{\partial A_1}{\partial x} + \frac{\partial A_2}{\partial y} + \frac{\partial A_3}{\partial z} \right) + \left(\frac{\partial B_1}{\partial x} + \frac{\partial B_2}{\partial y} + \frac{\partial B_3}{\partial z} \right)$$

$$= (\vec{\nabla} \cdot \vec{A}) + (\vec{\nabla} \cdot \vec{B})$$

$$= \text{div}(\vec{A}) + \text{div}(\vec{B})$$

So, it is saying if let me write A and B. So, if A and B are two vector functions then, or let me write like divergence of A plus B equals to divergence of A plus divergence of B. Let us see the proof of it. So, divergence of A plus B will become del operator dot product with the sum of these two vector functions. So, we need to prove that divergence of vector A plus B equals to del dot A plus B.

Now if vector a is having component like $A_1 \hat{i} + A_2 \hat{j} + A_3 \hat{k}$ and vector B is having component as $B_1 \hat{i} + B_2 \hat{j} + B_3 \hat{k}$. Then as you know that the sum of these two vectors will be having $A_1 + B_1$ is the i component plus $A_2 + B_2$ as the j component plus $A_3 + B_3$ as the k component. So, now, divergence of A plus B will become del by del x of phi component plus of phi component, it mean j component and del by del z of k component.

So, this since the partial derivative operator is a linear operator. So, I can write del A 1 over del x plus del A 2 over del y plus del A 3 over del z plus del B 1 over del x del B 2 over del y plus del B 3 over del z and this is nothing just dot product of del operator with vector function A plus the second square bracket is round bracket, is the dot product of the second round bracket is dot product of del operator with vector B A vector function B and this is divergence A plus divergence B.

(Refer Slide Time: 12:43)

I_2

Show that $\text{div}(A \times B) = (\text{curl } A) \cdot B - (\text{curl } B) \cdot A$

$$\begin{aligned} \text{div}(A \times B) &= \sum \hat{i} \cdot \frac{\partial}{\partial x} (A \times B) \\ &= \sum \hat{i} \cdot \left(\frac{\partial A}{\partial x} \times B + A \times \frac{\partial B}{\partial x} \right) \quad \left[\because \frac{d}{dt}(\mathbf{u} \times \mathbf{v}) = \frac{d\mathbf{u}}{dt} \times \mathbf{v} + \mathbf{u} \times \frac{d\mathbf{v}}{dt} \right] \\ &= \sum \hat{i} \cdot \left(\frac{\partial A}{\partial x} \times B \right) + \sum \hat{i} \cdot \left(A \times \frac{\partial B}{\partial x} \right) \\ &= \sum \left(\hat{i} \times \frac{\partial A}{\partial x} \right) \cdot B - \sum \left(\hat{i} \times \frac{\partial B}{\partial x} \right) \cdot A \quad \left[\because (\mathbf{a} \cdot \mathbf{b}) \times \mathbf{c} = (\mathbf{a} \times \mathbf{b}) \cdot \mathbf{c} \right] \\ &= (\text{curl } A) \cdot B - (\text{curl } B) \cdot A \end{aligned}$$

VT ROOKIEE NPTEL ONLINE CERTIFICATION COURSE 3

This is what we need to prove the next identity which are going to prove, is show that divergence of vector A cross vector B, the cross product of A and B equals to curl A dot B minus curl B dot A. So, here divergence of A cross B written as in the short form and what is this short form. The short form is saying that the i component of this divergence can be written A in this way. So, if I take the dot product with i component, I will get del by del x of A cross B and since this is here. So, similarly we can extend it; the components of j and component of k.

Means it will become plus j dot del over del y over A cross B plus k dot product with del by del z over A cross p. So, in this way, so this is the short notation. Now, del by del x of A cross B, if I am having B by d t of u cross v, I can write it d u or d t cross v plus u cross d v over d t. So, applying this property here I will get disturbed del by del x of A cross B as del over del x cross B plus A cross del v over del x. Now, I can write it in the term, in the sum of two different terms. So, first term will become i cap dot del A over del x cross B.

So, up to here plus I kept A cross del B over del x. Now we are having this particular property of vectors that a dot b cross c can be written as a cross b dot c. So, in this way, this particular term I can write as i cross del A over del x dot B, and this I have taken the minus, because I am taking inside i cross del v over del x. So, I am changing the order of this A cross del B over del x.

So, I have written $\nabla \times (\mathbf{v} \cdot \nabla \mathbf{x})$ dot product with \mathbf{A} . Now what is this? This is $\text{curl}(\mathbf{A} \cdot \mathbf{B})$ minus $\text{curl}(\mathbf{B} \cdot \mathbf{A})$ and this way we have done the proof of this particular identity. The next identity again a bit tricky proof and it is saying that. So, that $\text{curl}(\mathbf{p} \times \mathbf{q})$ like in the earlier one, we are having divergence here.

(Refer Slide Time: 15:25)

Identities

I_3

Show that $\text{curl}(\mathbf{A} \times \mathbf{B}) = (\mathbf{B} \cdot \nabla) \mathbf{A} - \mathbf{B} \text{div}(\mathbf{A}) + \mathbf{A} \text{div}(\mathbf{B}) - (\mathbf{A} \cdot \nabla) \mathbf{B}$

$$\begin{aligned} \text{curl}(\mathbf{A} \times \mathbf{B}) &= \sum \hat{i} \times \frac{\partial}{\partial x} (\mathbf{A} \times \mathbf{B}) \\ &= \sum \hat{i} \times \left(\frac{\partial \mathbf{A}}{\partial x} \times \mathbf{B} + \mathbf{A} \times \frac{\partial \mathbf{B}}{\partial x} \right) \quad \left[\because \frac{d}{dt}(\mathbf{u} \times \mathbf{v}) = \frac{d\mathbf{u}}{dt} \times \mathbf{v} + \mathbf{u} \times \frac{d\mathbf{v}}{dt} \right] \\ &= \sum \hat{i} \times \left(\frac{\partial \mathbf{A}}{\partial x} \times \mathbf{B} \right) + \sum \hat{i} \times \left(\mathbf{A} \times \frac{\partial \mathbf{B}}{\partial x} \right) \end{aligned}$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE

4

Now, we are taking $\text{curl}(\mathbf{A} \times \mathbf{B})$ equals to $\mathbf{B} \cdot \nabla \mathbf{A}$ minus $\mathbf{B} \text{div}(\mathbf{A})$ plus $\mathbf{A} \text{div}(\mathbf{B})$ minus $\mathbf{A} \cdot \nabla \mathbf{B}$. Please note that these two square round bracket term $\mathbf{B} \cdot \nabla$ and $\mathbf{A} \cdot \nabla$, these are basically operators and how I can define these operators. So, if my \mathbf{B} is, let us say $B_1 \hat{i} + B_2 \hat{j} + B_3 \hat{k}$ ∇ operator is define as $\nabla_x \hat{i} + \nabla_y \hat{j} + \nabla_z \hat{k}$.

(Refer Slide Time: 15:55)

$$\vec{B} = B_1 \hat{i} + B_2 \hat{j} + B_3 \hat{k}$$

$$\vec{\nabla} = \frac{\partial}{\partial x} \hat{i} + \frac{\partial}{\partial y} \hat{j} + \frac{\partial}{\partial z} \hat{k}$$

$$(\vec{B} \cdot \vec{\nabla}) = \left(B_1 \frac{\partial}{\partial x} + B_2 \frac{\partial}{\partial y} + B_3 \frac{\partial}{\partial z} \right)$$

$$\phi = xyz$$

$$(\vec{B} \cdot \vec{\nabla}) \phi = \left(B_1 \frac{\partial}{\partial x} + B_2 \frac{\partial}{\partial y} + B_3 \frac{\partial}{\partial z} \right) \phi$$

$$= [B_1 yz + B_2 xz + B_3 xy]$$

So, now, B dot del is in operator and it is something B 1 del by del x. Please do not write it del B 1 over del x no plus B 2 del over del y plus B 3 del by del z. For example, if one my some a scalar function is phi. So, let us say phi x y z, then B dot del phi will become B 1 del by del x plus B 2 del by del y plus B 3 del by del z phi ok. So, it will become B 1 del phi over del x. So, now, this B 1 del by del x.

Operating on phi; So, it will become B 1 y z plus B 2 x z plus B 3 x y. So, it will be a scalar quantity; this operator operating on a scalar function. As I told you do not write it del B 1 over del x. If you write it del B 1 over del x, then del B 1 over del x into phi plus del B 1 B 2 over del x into phi plus del B 3 over del x into phi. These two teams are quite different here, you are operating partial derivatives on phi. Here you have made a mistake, because you have done the partial differentiation of B 1 B 2 and B 3.

So, this is wrong. So, basically you cannot write it del B 1 over del x plus del B 1 over del y del B 3 over del z. please be careful about this operator. So, now, I need to prove that curl of A cross B v dot del operator operating on A minus B divergence A plus A divergence B minus. the operator A dot del operating on B. Now if I take A curl of cross B in short notation, I can write it some i cross del by del x of A cross B.

Now again using the same property which we have used in the earlier example that d by d t of u cross v equals to the d over d t cross v plus u cross d v over d t, this can be written as i cross del over del x cross B plus A cross del B over del x. Now again like in

the earlier identity I will break it in two terms; one is $\vec{i} \times \text{del } A$ over $\text{del } x$ cross B plus $\vec{i} \times A$ cross $\text{del } B$ over $\text{del } x$.

(Refer Slide Time: 19:56)

And now I will use the property of vectors which is saying say mediate a cross $\vec{b} \times \vec{c}$ equals to $\vec{a} \cdot \vec{c}$ into \vec{b} minus $\vec{a} \cdot \vec{b}$ into \vec{c} , because here in the identity which I am doing, I am having this kind of two terms; So, using this property. So, using the property just I mentioned I can write these two terms.

(Refer Slide Time: 20:38)

Identities

I_3 cont...

$$\begin{aligned}
 &= \sum (B \cdot \hat{i}) \frac{\partial A}{\partial x} - \sum (\hat{i} \cdot \frac{\partial A}{\partial x}) B + \sum (\hat{i} \cdot \frac{\partial B}{\partial x}) A - \sum (A \cdot \hat{i}) \frac{\partial B}{\partial x} \\
 &= \sum \left((B \cdot \hat{i}) \frac{\partial}{\partial x} \right) A - B \operatorname{div}(A) + A \operatorname{div}(B) - \sum \left((A \cdot \hat{i}) \frac{\partial}{\partial x} \right) B \\
 &= (B \cdot \nabla) A - B \operatorname{div}(A) + A \operatorname{div}(B) - (A \cdot \nabla) B
 \end{aligned}$$

5

In this way and finally, $\mathbf{B} \cdot \nabla \mathbf{A}$, I can write $\mathbf{B} \cdot \nabla$ as $\nabla \cdot \mathbf{B}$ at a, because $\mathbf{v} \cdot \nabla$ will be the component of \mathbf{B} in the direction of ∇ . So, this $\nabla \cdot \mathbf{A}$ over $\nabla \cdot \mathbf{x}$ into \mathbf{B} I can write, because it is nothing just divergence of \mathbf{A} . So, I can write \mathbf{B} times divergence of \mathbf{A} . This $\nabla \cdot \mathbf{B}$ over $\nabla \cdot \mathbf{x}$ is \mathbf{A} times divergence of \mathbf{B} .

And finally, this $\mathbf{A} \cdot \nabla \mathbf{B}$ over $\nabla \cdot \mathbf{x}$, I can take $\nabla \cdot \mathbf{y}$ over $\nabla \cdot \mathbf{x}$ inside the bracket and \mathbf{B} I can take out. So, this is $\mathbf{B} \cdot \nabla$ operating on \mathbf{A} minus \mathbf{B} divergence \mathbf{A} plus \mathbf{A} divergence \mathbf{B} minus $\mathbf{A} \cdot \nabla$ operating on \mathbf{B} and this is what we need to do my next identity is show that gradient of $\mathbf{A} \cdot \mathbf{B}$ equals to $\mathbf{B} \cdot \nabla$ plus $\mathbf{A} \cdot \nabla \mathbf{B}$ plus $\mathbf{B} \times \text{curl } \mathbf{A}$ plus $\mathbf{A} \times \text{curl } \mathbf{B}$.

Show that $\text{grad}(\mathbf{A} \cdot \mathbf{B}) = (\mathbf{B} \cdot \nabla) \mathbf{A} + (\mathbf{A} \cdot \nabla) \mathbf{B} + (\mathbf{B} \times \text{curl}(\mathbf{A})) + (\mathbf{A} \times \text{curl}(\mathbf{B}))$

$$\nabla(\mathbf{A} \cdot \mathbf{B}) = \sum_i \hat{i} \frac{\partial}{\partial x_i} (\mathbf{A} \cdot \mathbf{B}) = \sum_i \hat{i} \left(\frac{\partial \mathbf{A}}{\partial x_i} \cdot \mathbf{B} + \mathbf{A} \cdot \frac{\partial \mathbf{B}}{\partial x_i} \right)$$

Using the fact that $(\mathbf{a} \times \mathbf{b}) \cdot \mathbf{c} = (\mathbf{a} \cdot \mathbf{c})b - (\mathbf{a} \cdot \mathbf{b})c$, we get

$$\sum_i \left(\mathbf{A} \cdot \frac{\partial \mathbf{B}}{\partial x_i} \right) \hat{i} = \sum_i (\mathbf{A} \cdot \hat{i}) \frac{\partial \mathbf{B}}{\partial x_i} - \sum_i \mathbf{A} \times \left(\frac{\partial \mathbf{B}}{\partial x_i} \times \hat{i} \right)$$

$$= \sum_i (\mathbf{A} \cdot \hat{i}) \frac{\partial \mathbf{B}}{\partial x_i} + \sum_i \mathbf{A} \times \left(\hat{i} \times \frac{\partial \mathbf{B}}{\partial x_i} \right) = \sum_i \left(\mathbf{A} \cdot \hat{i} \frac{\partial}{\partial x_i} \right) \mathbf{B} + \sum_i \mathbf{A} \times \left(\hat{i} \times \frac{\partial \mathbf{B}}{\partial x_i} \right)$$

$$= (\mathbf{A} \cdot \nabla) \mathbf{B} + \mathbf{A} \times (\nabla \times \mathbf{B})$$

VT ROORKEE NPTEL ONLINE CERTIFICATION COURSE

So, sorry \mathbf{A} is missing here. So, it is $\mathbf{B} \cdot \nabla$ operating on \mathbf{A} , so gradient of $\mathbf{A} \cdot \mathbf{B}$. In the short I can write it $\nabla \cdot \mathbf{x}$ operating on $\mathbf{A} \cdot \mathbf{B}$. So, it will be summation $\nabla \cdot \mathbf{x}$ $\mathbf{A} \cdot \mathbf{B}$ plus $\mathbf{A} \cdot \nabla \mathbf{B}$ by $\nabla \cdot \mathbf{x}$. Now using the fact that $\mathbf{a} \times \mathbf{b} \times \mathbf{c}$ can be written in this way we get, sorry this bracket should be here $\mathbf{a} \times \mathbf{b} \times \mathbf{c}$. So, I can write it in this way $\mathbf{A} \cdot \nabla \mathbf{B}$ over $\nabla \cdot \mathbf{x}$ I can be written in this way; that is this term can be, this term can be written as this minus this one.

So, this term I am taking this side and this term I have taken in the right hand side. So, $\mathbf{A} \cdot \nabla \mathbf{B}$ over $\nabla \cdot \mathbf{x}$ I can be written as $\mathbf{A} \cdot \nabla \mathbf{B}$ over $\nabla \cdot \mathbf{x}$ minus $\mathbf{A} \times \nabla \mathbf{B}$ over $\nabla \cdot \mathbf{x}$ cross $\nabla \cdot \mathbf{x}$. So, this way I can write this $\mathbf{A} \cdot \nabla \mathbf{B}$ over $\nabla \cdot \mathbf{x}$ minus $\mathbf{A} \times \nabla \mathbf{B}$ over $\nabla \cdot \mathbf{x}$ equals to $\mathbf{A} \cdot \nabla \mathbf{B}$ by $\nabla \cdot \mathbf{x}$. So, $\nabla \cdot \mathbf{x}$ I have taken inside, like

we have done in the earlier identity plus $\mathbf{A} \times \mathbf{i} \times \nabla \mathbf{B}$ over $\nabla \cdot \mathbf{x}$. And this I can write as $\mathbf{A} \cdot \nabla$ operating on \mathbf{B} plus $\mathbf{A} \times \nabla \times \mathbf{B}$. So, this I am getting from this term which is this one the second term. Similarly, I will get from the first term which is given as $\mathbf{B} \cdot \nabla \mathbf{A}$ over $\nabla \cdot \mathbf{x}$, I can write in this way.

(Refer Slide Time: 23:34)

Identities

I_6 cont...

Similarly,

$$\sum \left(\mathbf{B} \cdot \frac{\partial \mathbf{A}}{\partial \mathbf{x}} \right) \hat{i} = (\mathbf{B} \cdot \nabla) \mathbf{A} + \mathbf{B} \times (\nabla \times \mathbf{A})$$

Hence we get,

$$\nabla(\mathbf{A} \cdot \mathbf{B}) = (\mathbf{B} \cdot \nabla) \mathbf{A} + (\mathbf{A} \cdot \nabla) \mathbf{B} + (\mathbf{B} \times \nabla \times \mathbf{A}) + (\mathbf{A} \times \nabla \times \mathbf{B})$$

i.e

$$\nabla(\mathbf{A} \cdot \mathbf{B}) = (\mathbf{B} \cdot \nabla) \mathbf{A} + (\mathbf{A} \cdot \nabla) \mathbf{B} + (\mathbf{B} \times \text{curl}(\mathbf{A})) + (\mathbf{A} \times \text{curl}(\mathbf{B}))$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 9

Hence, adding these two I will get the required identity. So, in this particular lecture we have seen some identities on divergence and curl, and we have seen about the Laplacian operator and which is nothing just divergence of gradient of a scalar function. We have also seen that a conservative vector field will be having curl 0.

So, with this I will end this lecture and we will learn a new concept; that is a new type of integral that is called line integral in the next lecture.

Thank you very much.
