**Lecture – 34**  
**Line Integral - I**

Hello friends. So, welcome to the 34th lecture of this course and in this lecture I will introduce line integral.

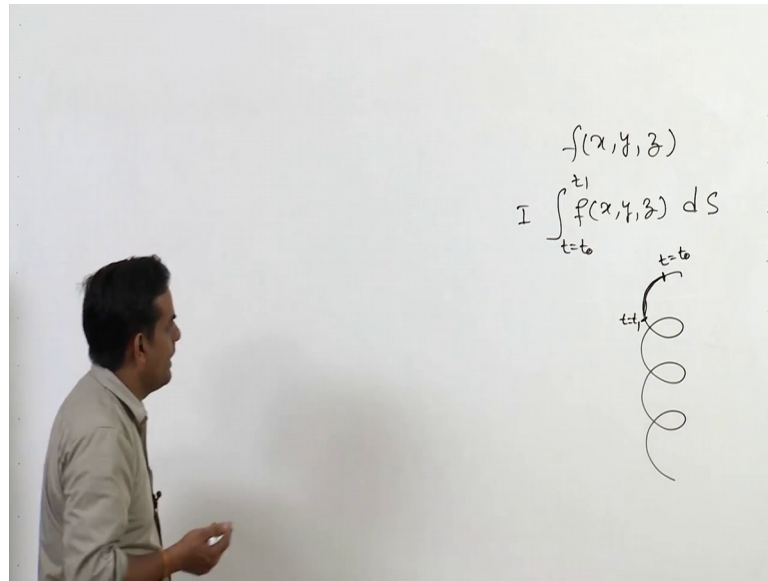

(Refer Slide Time: 00:37)

So, we have known about the definite integral; definite integral is something like this  $I$  equals to  $a$  to  $b$ ;  $f(x) dx$ . So, basically what is this? You are having your  $x$  axis,  $y$  axis, you are having a curve  $y$  equals to  $f(x)$ , you are having a point  $x$  equals to  $a$ ; another point  $x$  equals to  $b$ .

And now this  $I$  gives me this particular area; area under the curve and above the  $x$  axis and here we are calculating this integral on the horizontal axis; from  $x$  equals to  $a$  to  $x$  equals to  $b$ . So, on a straight line, but all the curves are not straight lines. I can have a circle, I can have any other conic, I can have helix which is a space curve; we have seen the parametric representation of that curve just few lecture ago. Now if I ask you, you are having a function  $f$  which is a function of  $x, y, z$ .

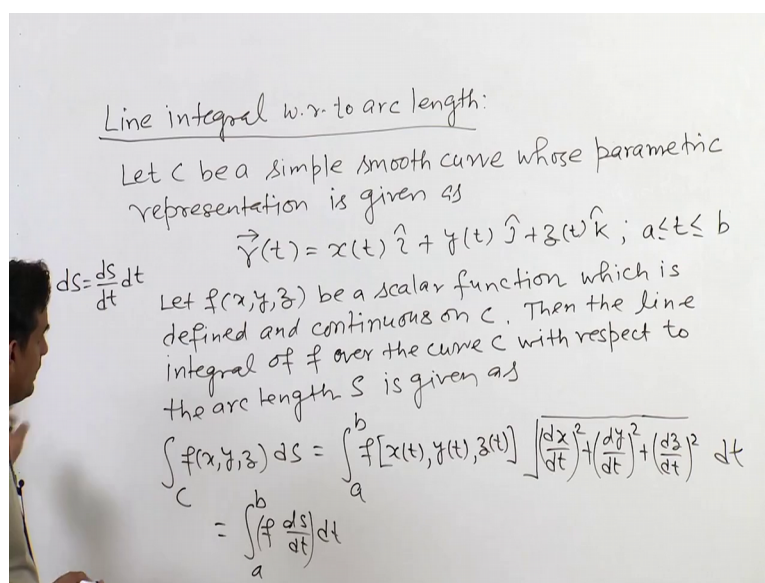

(Refer Slide Time: 02:12)

So,  $f$  is a function of  $x$ ,  $y$  and  $z$ . Now what you do? Calculate  $f$  of  $x$ ,  $y$ ,  $z$  that is the integration of  $f$  with respect to arc length of a given smooth curve. For example, if I am having a helix; so, let us say this is having some  $t$  equals to  $t_0$  and here I am having  $t$  equals to  $t_1$ . So, find the integral  $t$  equals to  $t_0$  to  $t_1$  along this arc length.

So, now, please see the difference. In the definite integral we were having a straight line on the horizontal axis; an interval from  $a$  to  $b$ . Here my  $t$  is changing or curve is changing not in a straight line; it is along a curve. So, such type of integral are called line integral. Here it can be a scalar function or it can be a vector function also, it can be with respect to arc length or we can define it in other way also. So, let us define it formally. This is just a motivation for you that what we mean by line integral.

(Refer Slide Time: 04:21)

So, we have to integrate a function over a smooth curve for a given arc of the curve ok. So, let me write the formal definition of line integral with respect to arc length. So, let  $C$  be a simple a smooth curve whose parametric representation is given as  $r(t)$  equals to  $x(t)\hat{i} + y(t)\hat{j} + z(t)\hat{k}$ ; here  $t$  is let us say between  $a$  to  $b$ . Let  $f$  of  $x, y, z$  be a scalar function which is defined and continuous on  $C$ . Then the line integral of function  $f$  over the curve  $C$  with respect to arc length; let us say arc length is  $S$ . So, with respect to the arc length  $S$  is given as integral over  $C$   $f$  of  $x, y, z$   $ds$ .

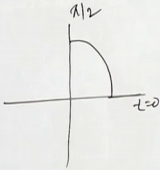

So, this I can write  $a$  to  $b$ . Let me write this  $f$  in terms of parametric representation means in terms of  $t$ . So,  $x$  will be  $x(t)$ ,  $y$  will be  $y(t)$  and  $z$  I can write  $z(t)$ . So, now, it will be a function of  $t$ . Now let us what we do with this  $ds$ ? So, you know that I can write  $ds$  equals to  $ds$  by  $dt$  into  $dt$  and what is  $ds$  by  $dt$ ?  $dx$  by  $dt$  is magnitude of  $r'(t)$ .

So, I can write it a square root of  $dx$  by  $dt$  whole square plus  $dy$  over  $dt$  whole square plus  $dz$  over  $dt$  whole square into  $dt$  and the limits of integral is from  $a$  to  $b$ . So, basically what I am doing? I am writing  $f ds$  over  $dt$  into  $dt$ . So, here everything will be in terms of  $t$  and limits are also in of  $t$  from  $a$  to  $b$ . So, we can evaluate this particular integral. So, let us take one or two example of this particular thing and then we will move to next definition.

(Refer Slide Time: 09:14)

Ex Evaluate  $\int_C xy^2 ds$ , where  $C$  is the curve defined by  
 $x = 2\cos t$ ;  $y = 2\sin t$  and  $0 \leq t \leq \frac{\pi}{2}$

Sol<sup>n</sup>:  $\vec{r}(t) = 2\cos(t)\hat{i} + 2\sin(t)\hat{j}$   
 $\vec{r}'(t) = -2\sin(t)\hat{i} + 2\cos(t)\hat{j}$   
 $|\vec{r}'(t)| = \sqrt{4\sin^2 t + 4\cos^2 t} = 2 \left( = \frac{ds}{dt} \right)$   
 $\Rightarrow I = \int_C xy^2 ds = \int_0^{\pi/2} 2\cos t \cdot 4\sin^2 t (2) dt$   
 $= 16 \int_0^{\pi/2} \cos t \sin^2 t dt = 16 \left[ \frac{\sin^3 t}{3} \right]_0^{\pi/2} = \frac{16}{3}$

So, let us take example. Evaluate integral over a curve  $C$  function is given by  $x$  into  $y$  square with respect to arc length  $S$  over the curve  $C$ , where  $C$  is the curve defined by  $x$  equals to  $2\cos t$ ;  $y$  equals to  $2\sin t$  and  $0$  to  $t$  to  $\pi$  by  $2$ . So, if we take, so if we see the curve  $C$ , so, it is nothing, but just a circle of radius  $2$  in the first quadrant because  $x$  is  $2\cos t$ ,  $y$  is  $2\sin t$ . So,  $x$  square plus  $y$  square equals  $2^2 + 2^2 = 4 + 4 = 8$  and since  $t$  is moving from  $0$  to  $\pi$  by  $2$ .

So, from  $t$  equals to  $0$  to  $\pi$  by  $2$ ; So, here  $\vec{r}(t)$  is given as  $2\cos t \hat{i} + 2\sin t \hat{j}$ . So, now,  $\vec{r}'(t)$  will become  $-2\sin t \hat{i} + 2\cos t \hat{j}$ . Magnitude of  $\vec{r}'(t)$  will be square root; for  $\sin^2 t$  plus for  $\cos^2 t$ , so, for  $\sin^2 t + 4\cos^2 t$ . So, basically it is  $dx$  by  $dt$  whole square, it is  $dy$  by  $dt$  whole square. So, it comes out to be  $2$ . So, basically I can write  $ds$  as  $2$  times  $dt$  because it is my  $ds$  over  $dt$ . So, now, line integral is  $I$  equals to  $\int_C xy^2 ds$  over the curve  $C$  can be written as  $t$  is moving from  $0$  to  $\pi$  by  $2$ ,  $x$  is twice  $\cos t$   $y$  is  $2\sin t$ . So, it will become  $4\sin^2 t$  and then  $ds$  over  $dt$  is  $2$  and finally,  $dt$ . So, this becomes  $16 \int_0^{\pi/2} \cos t \sin^2 t dt$ .

This will become  $16 \int_0^{\pi/2} \cos t \sin^2 t dt$  or I can write directly the integration  $\sin^3 t$  over  $3$  from  $0$  to  $\pi$  by  $2$  and this comes out to be  $16$  by  $3$ ; that is the final answer of this problem. So, hence the value of this integral over this curve,  $t$  is moving from  $0$  to  $\pi$  by  $2$  is  $16$  by  $3$ .

(Refer Slide Time: 13:48)

Ex.: Evaluate  $\int_C (x^2 + yz) ds$ , where  $C$  is the curve defined by  
 $x = 4y$  and  $z = 3$  from  $(2, \frac{1}{2}, 3)$  to  $(4, 1, 3)$

Soln: Let  $x = t$ ; then  $y = \frac{t}{4}$  and  $z = 3$   
the parametric representation of  $C$  is  
 $\vec{r}(t) = t \hat{i} + \frac{t}{4} \hat{j} + 3 \hat{k}$ ;  $2 \leq t \leq 4$   
 $\vec{r}'(t) = \hat{i} + \frac{1}{4} \hat{j}$   
 $|\vec{r}'(t)| = \sqrt{1 + \frac{1}{16}} = \frac{\sqrt{17}}{4}$   
 $ds = \frac{\sqrt{17}}{4} dt$

$I = \int_C (x^2 + yz) ds$   
 $= \int_2^4 \left( t^2 + \frac{3}{4} t \right) \frac{\sqrt{17}}{4} dt$   
 $= \frac{139\sqrt{17}}{24}$

Now let us take one more example in which we will change the definition of curve in another way. So, evaluate a line integral over the curve  $C$  of a function  $x$  square plus  $y z$  with respect to arc length  $S$ ; where  $C$  is the curve defined by  $x$  equals to  $4y$  and  $z$  equals to  $3$ ; from  $2, 1$  by  $2, 3$  to  $4, 1, 3$  ok. So, here first we need to write the parametric representation of the curve  $C$ ; then we need to calculate magnitude of  $r$  dash  $t$  and finally, we will solve the integral in terms of  $t$ .

So, here let  $x$  equals to  $t$ . So, I am writing the parametric representation of the curve  $C$ . If  $x$  equals to  $t$  then  $y$  will become  $t$  by  $4$  because  $x$  equals to  $4y$  and  $z$  is given as  $3$ . So, the parametric representation of  $C$  is  $r$   $t$  equals to  $t$   $i$  plus  $t$  by  $4$   $j$  plus  $3$   $k$ ; where  $t$  is moving from  $2$  to  $4$ . Why I am writing this  $2$  to  $4$  because  $t$  equals  $x$  and  $x$  is going from  $2$  to  $4$ . So, from here like the earlier example I will calculate  $r$  dash  $t$  which will become  $i$  cap plus  $1$  by  $4$   $j$  cap and so on because this component will become  $0$ . So, here  $r$  dash  $t$ , the magnitude of this vector will be square root  $17$  by  $4$ .

So, this will become basically square root  $1$  plus  $1$  by  $16$ . So, it will become square root  $17$  by  $4$ . So, from here I can write  $ds$  equals to square root  $17$  by  $4$   $dt$ . Now integral over the curve  $C$   $x$  square plus  $yz$   $ds$  can be written as  $t$  is moving  $2$  to  $4$ ;  $x$  square is  $t$  square  $y$  is  $t$  by  $4$ ;  $z$  is  $3$ . So,  $3$  by  $4$   $t$  it is square root  $17$  by  $4$   $dt$ ; so, this comes out to be  $139$  square root  $17$  by  $24$ , after solving this particular integral. So, in this way we can solve such this kind of problem.

(Refer Slide Time: 18:39)

Line integral of vector function

Let  $C$  be a simple smooth curve whose parametric representation is given as

$$\vec{r}(t) = x(t)\hat{i} + y(t)\hat{j} + z(t)\hat{k}; a \leq t \leq b$$

Let  $\vec{V}(x, y, z) = V_1(x, y, z)\hat{i} + V_2(x, y, z)\hat{j} + V_3(x, y, z)\hat{k}$  be a vector function defined and continuous on curve  $C$ . Then the line integral of  $\vec{V}$  over the curve  $C$  is given as

$$\int_C \vec{V} \cdot d\vec{r} = \int_C V_1 dx + V_2 dy + V_3 dz$$

$$= \int_a^b \left( \vec{V} \cdot \frac{d\vec{r}}{dt} \right) dt = \int_a^b [V_1(x(t), y(t), z(t))] \cdot \frac{dr}{dt} dt$$

$\frac{d\vec{r}}{dt} = \frac{d\vec{r}}{dt} dt$

So, my next definition is line integral of vector function. So, again let  $C$  be a simple smooth curve whose parametric representation is given as  $\vec{r}(t) = x(t)\hat{i} + y(t)\hat{j} + z(t)\hat{k}$ ; where  $t$  is let us say between  $a$  to  $b$ .

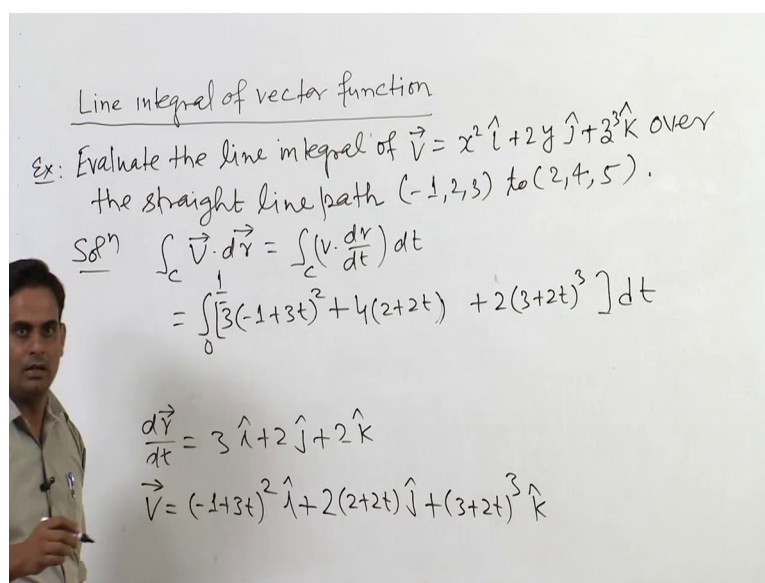

Let the vector function  $\vec{V}$  which is let us say  $V_1(x, y, z)$  is the component in  $i$  direction plus  $V_2(x, y, z)$  is the component in  $j$  direction plus  $V_3$  is the component in  $k$  direction. So, let vector function  $\vec{V}$  be a vector function defined and continuous on curve  $C$ . Here continuous means all the 3 components  $V_1, V_2, V_3$  are continuous on the curve  $C$ . Then the line integral of the function  $\vec{V}$ , over the curve  $C$  is given as the integral over  $C$   $\vec{V} \cdot d\vec{r}$ .

So, basically if I write it in another way it can be written as  $V_1 dx + V_2 dy + V_3 dz$  because  $\vec{V}$  as well as  $d\vec{r}$  are the vector functions. So, their dot product will be a scalar function and this scalar function will be  $V_1 dx + V_2 dy + V_3 dz$  or I can write it in terms of  $t$ . So,  $t$  is moving  $a$  to  $b$ ; this  $d\vec{r}$  I can write in another way. And what will be the another way of writing this  $d\vec{r}$ ? It will be because we know that.

So, another way will be  $d\vec{r}$  I can write as  $\frac{d\vec{r}}{dt} dt$ . So, this will become  $\vec{V} \cdot \frac{d\vec{r}}{dt} dt$ . So, this will become as you know integral over  $a$  to  $b$   $\vec{V}$  which is now a function of  $x(t), y(t), z(t)$  and then dot product with  $\frac{d\vec{r}}{dt} dt$ . So, in this way we can define the line integral of vector functions.

(Refer Slide Time: 23:49)

Line integral of vector function

Ex: Evaluate the line integral of  $\vec{V} = x^2 \hat{i} + 2y \hat{j} + z^3 \hat{k}$  over the straight line path  $(-1, 2, 3)$  to  $(2, 4, 5)$ .

Sol<sup>n</sup>  $\int_C \vec{V} \cdot d\vec{r} = \int_C (\vec{V} \cdot \frac{d\vec{r}}{dt}) dt$

$$= \int_0^1 [3(-1+3t)^2 + 4(2+2t) + 2(3+2t)^3] dt$$

$$\frac{d\vec{r}}{dt} = 3\hat{i} + 2\hat{j} + 2\hat{k}$$

$$\vec{V} = (-1+3t)^2 \hat{i} + 2(2+2t) \hat{j} + (3+2t)^3 \hat{k}$$

Let us take one example of it that how to calculate this line integral for a given vector function and a given curve. So, evaluate the line integral of the vector function  $V$  equals to  $x$  square  $i$  plus  $2y$   $j$  plus  $z$  cube  $k$  over the straight line path; let us take minus  $1, 2, 3$  to something  $2, 4, 5$ . So, first of all I have to write the parametric representation of this straight line.

So, the parametric representation of the straight line is given as so,  $r$   $t$  equals to I will write from here; so, minus  $i$  plus  $2j$  plus  $3k$  plus  $t$  times  $2$  minus minus  $1$ , so,  $2$  plus  $1$ ;  $3i$  plus  $4$  minus  $2$ ;  $2j$  plus  $5$  minus  $3$ ;  $2k$  and  $t$  is between  $0$  to  $1$ . So, when  $t$  is  $0$ , I will get minus  $1, 2, 3$ ; when  $t$  is  $1$ , I will get  $3$  minus  $1$ ;  $2$ ;  $2$  plus  $2$ ;  $4$ ;  $2$  plus  $3$ ;  $5$ ; the another point end point of the line.

For this I can write minus  $1$  plus  $3t$   $i$  plus  $2$  plus  $2t$   $j$  plus  $3$  plus  $2t$   $k$  and  $t$  is between  $0$  to  $1$ . Now  $dr$  over  $dt$ ; so, it is given as  $3i$  plus  $2j$  plus  $2k$ . My vector  $V$  is given as  $x$  square  $i$ ; so, my  $x$  is now minus  $1$  plus  $3t$ . So, it will become minus  $1$  plus  $3t$  whole square  $i$  plus  $2y$ .

So,  $2y$  now from the curve  $y$   $t$  equals to  $2$  plus  $2t$ . So,  $2$  times  $2$  plus  $2t$  into  $j$  plus  $z$  cube. So, from the parametric representation of curve  $j$   $t$  is  $3$  plus  $2t$  cube  $k$ . So, I am having  $dr$  over  $dt$ ; I am having the vector  $V$  in terms of  $t$ . So, now, line integral of  $V$  over this is straight line can be given as  $\int_C \vec{V} \cdot d\vec{r}$  ok.

So, this I am writing  $\int_C \mathbf{V} \cdot d\mathbf{r}$  over  $dt$  and this will become the dot product of these two vectors. So,  $(3 - 1 + 3t)^2 + 2(2 + 2t)^2 + 2(3 + 2t)^2$  not  $j$  here ok. So, this one into  $dt$  and  $t$  is moving from 0 to 1. So, ultimately what we are having? We are having everything in terms of  $t$  and now we can calculate this particular definite integral and by calculating it we can get the value of this.

So, we can further simplify it; we can write in terms of  $t$  and then we will get a polynomial of degree 3; we can integrate it over  $t$  and we can simply substitute the limits. Now I have taken a constraint that the curve should be a smooth curve.

(Refer Slide Time: 30:30)

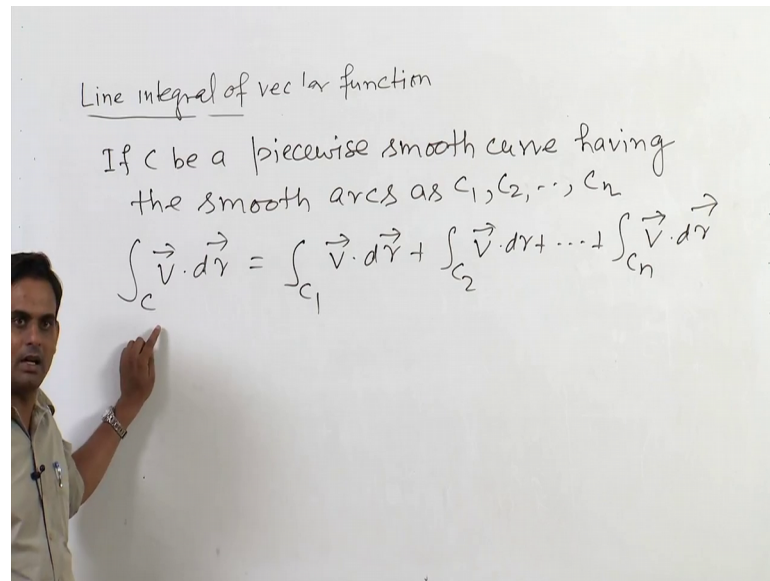

Now let us mild this particular constraint. So, if my curve is not is smooth, but it is piecewisely smooth. For example, it is a square or it is a triangle or it is something intersection of two conics. So, here it is having four piecewise; four sub curves, those are smooth. So, I will say that it is a piecewisely a smooth curve; it is having these three straight lines those are smooth, but if I put these corner points are not a smooth. So, I will say it is a piecewisely smooth curve; similarly these two curves. So, if the curve  $C$  is like that or it is something like this.

So, this is piece; this curve is piecewise smooth. These are the pieces of this curve; sub pieces those are is smooth. So, how we will define my line integral of a vector function on such a curve?

(Refer Slide Time: 32:01)

So, if  $C$  be a piecewise a smooth curve having the smooth arcs as  $C_1, C_2, C_n$ ; then the integral  $\vec{V} \cdot d\vec{r}$  over the curve  $C$  can be calculated or can be given as  $\vec{V} \cdot d\vec{r}$  plus integral over  $C_2$   $\vec{V} \cdot d\vec{r}$  plus; meaning is you calculate the line integral over each smooth arc and then sum all of them. So, the total will be the integral over the curve  $C$ .

(Refer Slide Time: 33:18)

So, let us take a simple example of this. So, example is evaluate let us say  $x\hat{i} + y\hat{j}$  and this is  $d\vec{r} \cdot d\vec{r}$  over a curve  $C$ ; where  $C$  is a curve given by this triangle.

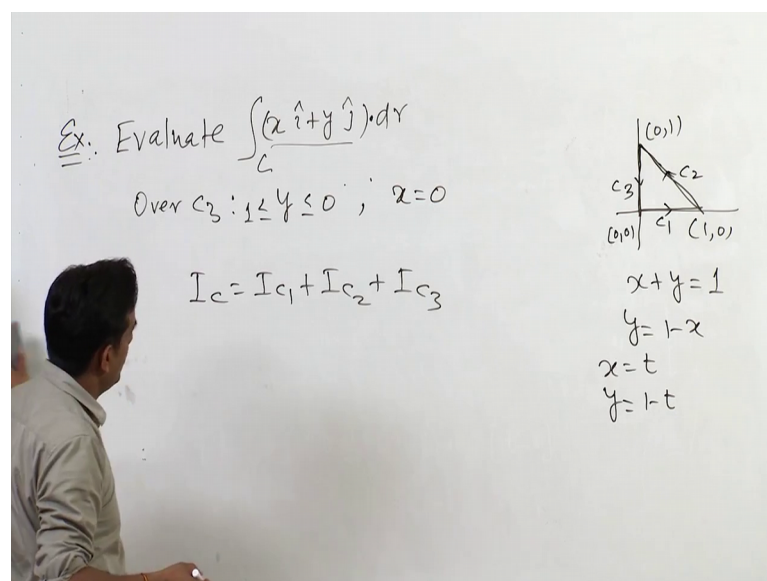

So, let us say  $0, 0; 1, 0$ . So, here I am having three smooth arc; one is  $C_1$  let us say; orientation is like this  $C_2$  and  $C_3$ ; so, having the positive orientation. So, first I will calculate is over  $C_1$ . So,  $C_1$  is something  $x$  is between  $0$  to  $1$  and  $y$  is  $0$ . So, for  $C_1$  parametric representation will become  $r$   $t$  is  $t$   $i$ ; where  $t$  is between  $0$  to  $1$ . So,  $dr$  over  $dt$  will be  $i$  only and here integral over  $C_1$  will be  $0$  to  $1$ ;  $x$  is  $t$  here,  $y$  is  $0$ .

So,  $t$   $i$  dot product with  $i$   $dt$  because this is  $dr$  over  $dt$  and  $dt$ . So, it will be  $0$  to  $1$   $t$   $dt$  and it comes out to be  $1$  by  $2$ . Similarly I will calculate on  $C_2$ . So,  $C_2$  is this line; this line is  $x$  plus  $y$  equals to  $1$  or I can write  $y$  equals to  $1$  minus  $x$ . So, if I take  $x$  equals to  $t$ ,  $y$  will become  $1$  minus  $t$ ; so, for on the curve  $C_2$ .

So, let me write it here  $I$  of  $C_1$  equals to  $1$  by  $2$ . So, on curve  $C_2$ ; so,  $C_2$  is  $x$  plus  $y$  equals to  $1$  in first quadrant. So, parametric representation will become  $t$   $i$  plus  $1$  minus  $t$   $j$ ; where  $t$  is between again  $0$  to  $1$ . So,  $dr$  over  $dt$  will be  $i$  minus  $j$  ok and then the integral will become  $0$  to  $1$ ,  $x$  is  $t$   $i$ .

So,  $x$  is  $t$   $i$  plus  $y$  is  $1$  minus  $t$   $j$ ; so, this is my this function over this curve and then dot product with  $i$  minus  $j$ . And finally,  $dt$  and limit is  $0$  to  $1$ . So, this I will get  $0$  to  $1$   $t$  minus  $1$  minus  $t$   $dt$ ;  $0$  to  $1$   $t$  plus  $t^2$  minus  $1$   $dt$ . This will become  $t$  square minus  $t$   $0$  to  $1$  and then  $1$  minus  $1$  is  $0$ .

(Refer Slide Time: 38:11)

So,  $\int_C \mathbf{C}_2$  is 0. Next I will calculate this integral over  $C_3$ . So, for  $C_3$  I am having this particular arc. So,  $y$  is from 1 to 0 and  $x$  is 0. So, similarly you can write the parametric representation, you can calculate the  $C_3$  and then  $\int_C$  will become  $\int_{C_1} + \int_{C_2} + \int_{C_3}$ . So, in this way we can solve this kind of problem where curve is not smooth, but piecewise is smooth.

So, with this I will close this lecture. So, in this lecture I have introduced the concept of line integral. Then we have seen line integral with respect to arc length, we have seen line integral of vector functions. We have taken few examples. In the next lecture we will continue from here and we will see some applications of line integral.

Thank you very much.
