Lecture - 05
Partial Derivatives-1

Hello friends, welcome to a lecture series on multivariable calculus so, today we will deal with partial derivatives. So, what is mean by a partial derivatives and how we can use this some solving some problems let us see.

(Refer Slide Time: 00:40)

The image shows a whiteboard with handwritten mathematical definitions. At the top, it says $z = f(x, y)$. Below that, the partial derivative of f with respect to x at the point (a, b) is defined as the limit of the difference quotient as h approaches 0. The final line states that $z = f(x, y)$ at the point $P(a, b, f(a, b))$ in the xy -plane.

$$z = f(x, y)$$
$$\left. \frac{\partial f}{\partial x} \right|_{(a, b)} = \text{partial derivative of } f \text{ wrt 'x' at } (a, b)$$
$$= \lim_{h \rightarrow 0} \frac{f(a+h, b) - f(a, b)}{h}$$
$$z = f(x, y) \quad \text{at } P(a, b, f(a, b)) \quad \text{in } xy\text{-plane.}$$

So, we start with one variable problems function of one variable we know that if your function is one variables say y equals to $f(x)$ where x belongs to \mathbb{R} say then if function is differentiable at a point say x equal to a , then we say that dy by dx at x equals to a or is equal to $f'(a)$ is equal to $\lim_{h \rightarrow 0} \frac{f(a+h) - f(a)}{h}$. So, this is how we defined derivative of a function at a point say x equal to a , it is simply $\lim_{h \rightarrow 0} \frac{f(a+h) - f(a)}{h}$.

Now, what does it mean what does it give derivative it simply gives slope of a tangent at a point x equal to a , if we have a curve y equals to $f(x)$ then at x equal to a it simply give slope of the tangent. It also represent rate of change of f along x axis rate at which the function changes along x axis. So, this we have already deal with we have already seen; what do we mean by function of derivative of function of single variables. Now, in multi

variable we have more than one independent variables so, we cannot define derivative like this ok.

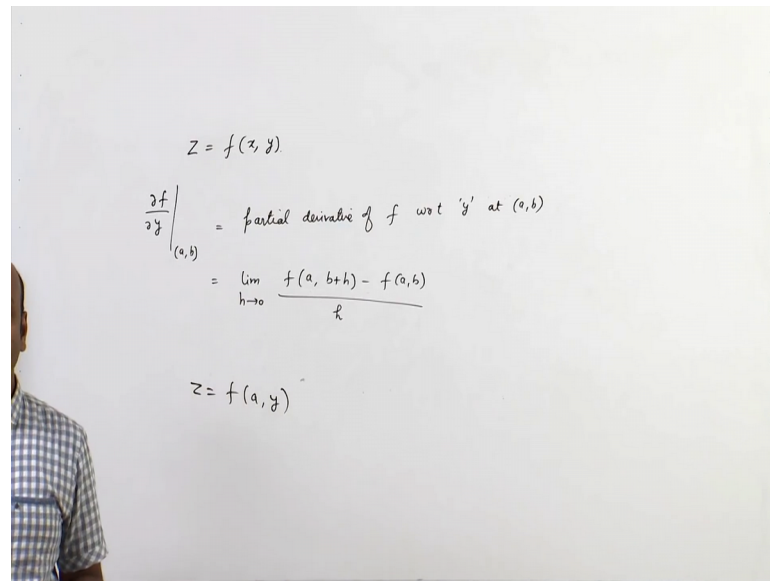

So, here we have function of variables more than one so, what we have here. Here we have a concept of partial derivatives so, what do you mean by partial derivative let us see. Suppose we have a function of x and y two variable function here x and y are independent variables and z is the dependent variable now we define $\frac{\partial f}{\partial x}$ it is simply partial derivative of f respect to x say at x equal to a . So, what does it mean it is partial derivative of f with respect to x at x equal to a ok.

Now, here when we deal with partial derivative of f respect to x ; that means, we are treating all other variables constant. So, we define this as $\lim_{h \rightarrow 0} \frac{f(a+h, b) - f(a, b)}{h}$. We are defining partial derivatives say at a point a comma b so, at a comma b because here we are having two variables a and b I mean x and y . So, it is $\lim_{h \rightarrow 0} \frac{f(a+h, b) - f(a, b)}{h}$ so, this is partial derivative of f respect to x at a comma b . So, simply we are changing only in x component y will remain same; that means, we are fixing y and changing only respect to x . Now what does it give? It simply gives rate of change of f along x axis.

Or rate of change of f along \hat{i} cap direction or we can define it like this z equal to $f(x, y)$ is a surface z equal to $f(x, y)$ is some surface. Now, y equal to b is a plane which cut the surface into a curve now the slope of the tangent for this curve z equals to $f_x(a, b)$ because y is equal to b at the point a $f(a, b)$ in the plane y equals to b . So, it is simply gives slope of the tangent for the curve this at a point this in the plane y equal to b because z equal to $f(x, y)$ is a surface when y equal to b cuts it will give a curve and the point is this. At this point the partial derivative of f with respect to x simply gives slope of the tangent of this curve in the plane this ok.

So, this is how we can defined $\frac{\partial f}{\partial x}$ or partial derivative of f respect to x geometrically. Similarly, when we talk about partial derivative of f respect to y so, with respect to y how can we define?

(Refer Slide Time: 05:51)

A photograph of a person's arm and shoulder on the left side, wearing a blue and white checkered shirt. They are standing next to a whiteboard. On the whiteboard, the following mathematical expressions are written in black marker:
$$Z = f(x, y)$$
$$\left. \frac{\partial f}{\partial y} \right|_{(a,b)} = \text{partial derivative of } f \text{ w.r.t 'y' at } (a,b)$$
$$= \lim_{h \rightarrow 0} \frac{f(a, b+h) - f(a,b)}{h}$$
$$z = f(a, y)$$

Now $\frac{\partial f}{\partial y}$ at (a, b) which is partial derivative of f with respect to variable y at (a, b) is simply $\lim_{h \rightarrow 0} \frac{f(a, b+h) - f(a, b)}{h}$. Now, here when we are differentiating partially f respect to y we are differentiating only with respect to y keeping all other variables constant. So, here a is constant we are fixing a we are changing only in the y component b plus h to b upon h .

So, this is how we can define rate of change we can define partial derivative of f respect to y again geometrically if we are talking about partial derivative of f respect to y it simply gives rate of change of f along y axis or rate of change of f along j cap direction or z equals to $f(x, y)$ is a surface and x equal to a is a plane. When x equal to a cuts the surface it will give a curve, which curve it will give this curve and the slope of the tangent for this curve at a point p in the plane x equal to a will represent $\frac{\partial f}{\partial y}$ at (a, b) . So, this is how we can define first order partial derivative of two variable functions respect to x and y .

Now, we will see some problems based on this let us see the first problem is it is f equal to $3x^3 + 4x^2y^2 - 6y^3$, now suppose you want to find $\frac{\partial f}{\partial x}$ at any point x, y .

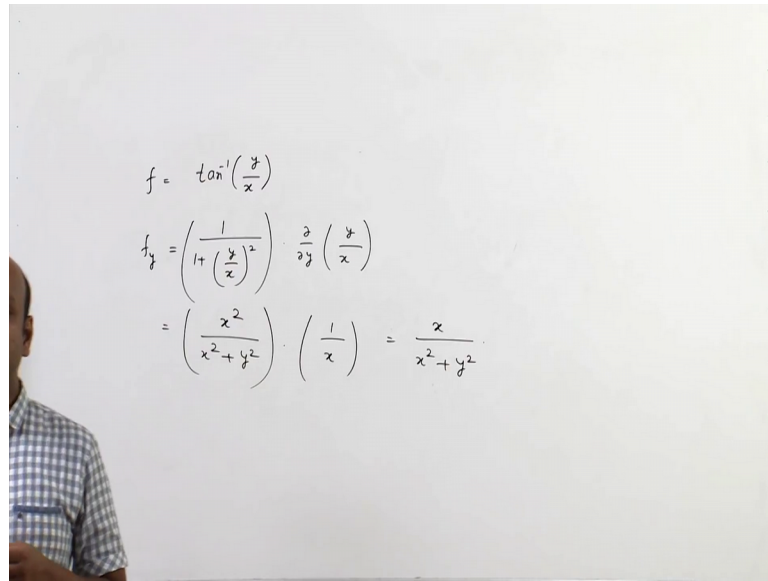

(Refer Slide Time: 08:01)

The image shows handwritten mathematical work on a piece of paper. It starts with the function $f = 3x^3 + 4x^2y^2 - 6y^3$. Below this, the partial derivative with respect to x is calculated: $\frac{\partial f}{\partial x} = 9x^2 + 8xy^2 - 0 = x[9x + 8y^2]$. Then, the partial derivative with respect to y is calculated: $\frac{\partial f}{\partial y} = 8x^2y - 18y^2$. To the right of this, two equations are written: $\frac{\partial f}{\partial x} = f_x$ and $\frac{\partial f}{\partial y} = f_y$.

So, del f upon del x is simply partial derivative of f is respect to x; that means, you have to simply differentiate this function respect to x keeping all other variables constant. So, derivative of this respect to x is simply 9 x square plus you have to keep y constant then this is 8 x y square minus 0 because we are treating this as a constant. So, this is x times 9 x plus 8 y square so, this is del f upon del x.

Now, similarly if you want to find out del f upon del y it is nothing, but now you have to differentiate f with respect to y partially; that means, you have to take x as a constant. So, this is 0 and this is 8 x square y minus it is 18 y square so, this is del f upon del y. Now, del f upon del x is sometimes also represented as f_x , f_x means del f upon del x now del f upon del y is also represented as f_y .

(Refer Slide Time: 10:03)

$$\begin{aligned} f &= \tan^{-1}\left(\frac{y}{x}\right) \\ f_x &= \left(\frac{1}{1 + \left(\frac{y}{x}\right)^2} \right) \cdot \frac{\partial}{\partial y} \left(\frac{y}{x} \right) \\ &= \left(\frac{x^2}{x^2 + y^2} \right) \cdot \left(\frac{1}{x} \right) = \frac{x}{x^2 + y^2} \end{aligned}$$

Now, the second problem the next problem now, f is $\tan^{-1} y$ upon x now what is f_x , f_x simply means $\frac{\partial f}{\partial x}$. Now, if you want to compute this it is $\tan^{-1} t$ derivative of $\tan^{-1} t$ is $\frac{1}{1+t^2}$ and then $\frac{\partial}{\partial x}$ of t which is $\frac{y}{x}$ this is simply equal to $\frac{x^2}{x^2 + y^2}$ into, now partial derivative of this respect to x is you have to take y as a constant it is $\frac{-y}{x^2 + y^2}$ because $\frac{1}{x}$ is $\frac{-1}{x^2}$ derivative of $\frac{1}{x}$ is $\frac{-1}{x^2}$. So, it is $\frac{-y}{x^2 + y^2}$ so, this is $\frac{\partial f}{\partial x}$.

Now, $\frac{\partial f}{\partial y}$ is f_y which is equals to again $\tan^{-1} t$ it is $\frac{1}{1+t^2}$ and then $\frac{\partial}{\partial y}$ of t again and it is equals to $\frac{x^2}{x^2 + y^2}$. Now, $\frac{\partial}{\partial y}$ of $\frac{y}{x}$ is simply $\frac{1}{x}$ and this is nothing, but $\frac{x}{x^2 + y^2}$. So, this is how we can find out $\frac{\partial f}{\partial x}$ or $\frac{\partial f}{\partial y}$ for some function of two variables ok.

(Refer Slide Time: 12:18)

Problems

- 1 Find the values of $\frac{\partial f}{\partial x}$ and $\frac{\partial f}{\partial y}$ in the following:
 - $f(x, y) = 3x^3 + 4x^2y^2 - 6y^3$
 - $f(x, y) = \tan^{-1}\left(\frac{y}{x}\right)$
- 2 Find $\frac{\partial z}{\partial x}$ and $\frac{\partial z}{\partial y}$ if the equation $x^2 + y^2 + z^2 + 6xyz = 1$, defines z as a function of two independent variables x and y .

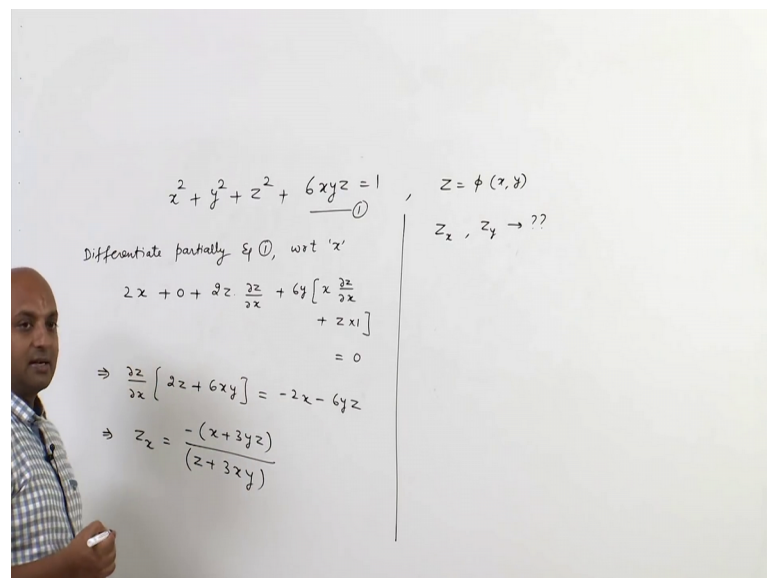

IIT ROORKEE
 NPTEL ONLINE
 CERTIFICATION COURSE

4

Now, let us solve second problem find z_x and z_y , if the equation, this defines z as a function of two independent variables x and y so, what is the function.

(Refer Slide Time: 12:32)

$$x^2 + y^2 + z^2 + 6xyz = 1 \quad \text{--- (1)} \quad , \quad z = f(x, y)$$

$$z_x, z_y \rightarrow ??$$

Differentiate partially Eq (1), w.r.t 'x'

$$2x + 0 + 2z \frac{\partial z}{\partial x} + 6y \left[x \frac{\partial z}{\partial x} + z \cdot 1 \right] = 0$$

$$\Rightarrow \frac{\partial z}{\partial x} [2z + 6xy] = -2x - 6yz$$

$$\Rightarrow z_x = \frac{-(x + 3yz)}{(z + 3xy)}$$

Now, the function is equation is x square plus y square plus z square plus $6x y z$ equal to 1 and here z is a function of x and y , x and y are independent variables and z depends on x or y , x and y . Now, how can we compute z_x , how we can compute z_x and z_y this we have to find out.

Now, we simply differentiate partially with respect to x so, differentiate partially say this equation is equation 1, equation 1 with respect to x. So, what we will obtain you see x square is 2 x when you differentiate partial with respect to x y square is because x and y are independent. Since, x and y are independent so, partial derivative of y respect to x will be 0. Now z is a function which depends on x and y. So, partial derivative of z respect to x will not be 0 it is t square means 2 t that is 2 z into del z upon del x plus six times.

Now, when we differentiate partial with respect to x we will take y as constant because y is independent of x so, we can take y also common, now inside bracket we are having x and z and both are the function of x. So, we have to apply product rule that is first as it is derivative of second that is del z upon del x plus second as it is derivative of first and derivative of 1 will be 0 respect to x. So, what we will obtain from here now let us collect del z upon del x this implies del z upon del x let us collect these terms 2 z plus 6 x y which is equal to the remaining terms put it on the right hand side. It is minus 2 x and it is minus 6 y z. So, what we are having this implies z x is equals to you will cancel 2 from both the sides so, it is minus of x plus 3 y z upon z plus 3 x y.

So, this is del z upon del x now if you want to find out del z upon del y so, similarly we can proceed for del z upon del y.

(Refer Slide Time: 16:06)

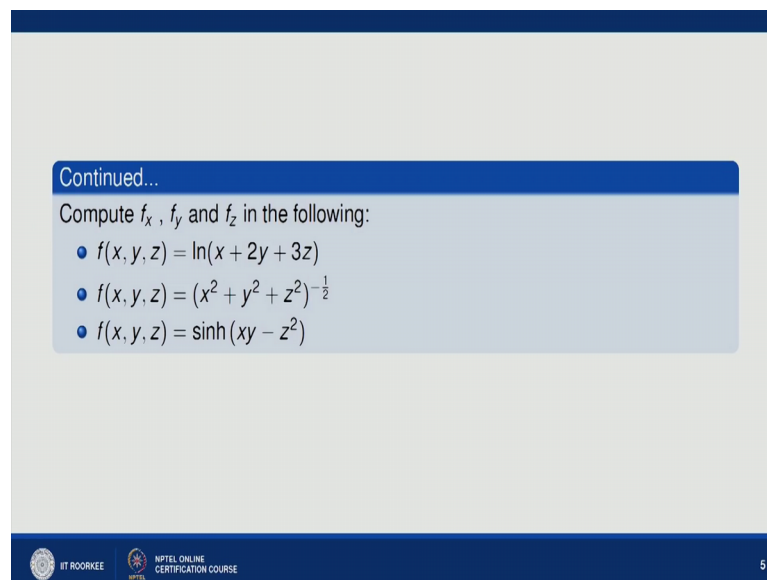

$$\begin{aligned}
 & x^2 + y^2 + z^2 + 6xyz = 1 \quad \text{--- (1)} \quad , \quad z = f(x, y) \\
 & \text{Differentiate Partially Eq (1), wrt 'y',} \quad z_x, z_y \rightarrow ?? \\
 & 0 + 2y + 2z \frac{\partial z}{\partial y} + 6x \left[y \frac{\partial z}{\partial y} + z \cdot 1 \right] = 0 \\
 & \Rightarrow \frac{\partial z}{\partial y} [2z + 6xy] = -2y - 6xz \\
 & \Rightarrow z_y = \frac{-(y + 3xz)}{(z + 3xy)}
 \end{aligned}$$

Now, again differentiate partially equation 1 with respect to y so, what we will obtain now x is independent of y . So, partial derivative of f_x with respect to y will be zero so, this is 0 plus y square the derivative partial derivative of y respect to y is $2y$. Of course, $\frac{\partial y}{\partial y}$ is 1 plus $2z$ into $\frac{\partial z}{\partial y}$ because z is a function of x and y , z depends on y plus now $6x$ you can take common. Now, y into z and both are the function of y so, you have to apply product rule here. So, it is y into first as it is derivative of second it is $\frac{\partial z}{\partial y}$ plus z into 1 which is equals to 0 .

So, this implies now collect terms of $\frac{\partial z}{\partial y}$ which is $2z$ plus $6xy$ equal to put all the remaining terms on the right hand side that is minus $2y$ minus $6xz$ cancel 2 from both the sides again. So, this implies zy will be equal to minus y plus $3xz$ upon z plus xy $3xy$ so, this is $\frac{\partial z}{\partial y}$. So, that is how if some implicit equations are given to us we can easily compute $\frac{\partial z}{\partial x}$ or $\frac{\partial z}{\partial y}$ if z is a function of x and y .

Now, we will solve some more problems where f is a function of three variables here the same definition will applicable for three variables also.

(Refer Slide Time: 18:11)

Continued...

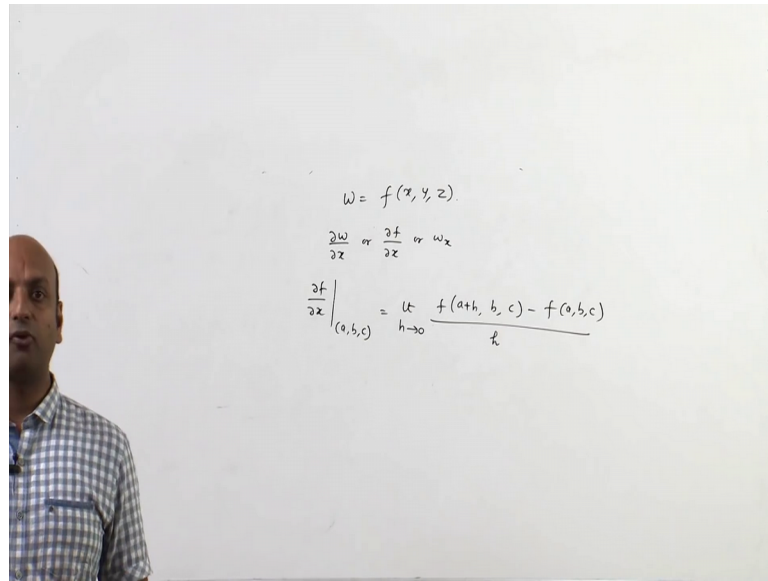

Compute f_x , f_y and f_z in the following:

- $f(x, y, z) = \ln(x + 2y + 3z)$
- $f(x, y, z) = (x^2 + y^2 + z^2)^{-\frac{1}{2}}$
- $f(x, y, z) = \sinh(xy - z^2)$

IIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 5

If we have function of three variables suppose you want to compute suppose you are having w is equals to $f(x, y, z)$.

(Refer Slide Time: 18:29)

$$w = f(x, y, z).$$
$$\frac{\partial w}{\partial x} \text{ or } \frac{\partial f}{\partial x} \text{ or } w_x$$
$$\left. \frac{\partial f}{\partial x} \right|_{(a,b,c)} = \lim_{h \rightarrow 0} \frac{f(a+h, b, c) - f(a, b, c)}{h}$$

Now, here x, y, z are independent variables and w is a dependent variable now if you want to compute ∂w by ∂x or we can say ∂f upon ∂x or we can say w_x . So, this is simply means this simply means we are treating x as a variable all other variables as constant. Suppose you want to define ∂f upon ∂x at some point say a, b, c so, how can I define this it is limit h tending to 0, f of a plus h, b, c minus f of a, b, c upon h . The same definition which we have used in for two variable functions the same will be followed for three variables or more than three variables. Similarly, we can define ∂f upon ∂y or ∂f upon ∂z .

Now, we will solve some problems based on this now suppose f is f of x, y, z is now first problem it is $1x$ plus $3y$ plus $6z$.

(Refer Slide Time: 19:43)

$$\begin{aligned} f(x, y, z) &= \ln(x + 3y + 6z) \\ f_x &= \frac{\partial f}{\partial x} = \left(\frac{1}{x + 3y + 6z} \right) \cdot \frac{\partial}{\partial x} (x + 3y + 6z) \\ &= \frac{1}{x + 3y + 6z} \\ f_y &= \frac{1}{(x + 3y + 6z)} \cdot \frac{\partial}{\partial y} (x + 3y + 6z) = \frac{3}{x + 3y + 6z} \\ f_z &= \left(\frac{1}{x + 3y + 6z} \right) \cdot \frac{\partial}{\partial z} (x + 3y + 6z) \\ &= \frac{6}{x + 3y + 6z} \end{aligned}$$

So, what will be f_x , f_x is $\frac{\partial f}{\partial x}$ and it is $\log t$, $\log t$ is derivative of $\log t$ is $\frac{1}{t}$ upon t that is $\frac{1}{x + 3y + 6z}$ and then $\frac{\partial}{\partial x}$ of t again this is equals to 1 upon $x + 3y + 6z$ because y and z are independent of x . So, derivative partial derivative of y or z with respect to x will be 0. Now, similarly f_y will be again $\frac{1}{t}$ upon t that is $\frac{1}{x + 3y + 6z}$ into $\frac{\partial}{\partial y}$ of $x + 3y + 6z$ which is 3 upon $x + 3y + 6z$.

Similarly, if you want to compute f_z it is again $\log t$ derivative $\log t$ is $\frac{1}{t}$ upon t it is $\frac{1}{x + 3y + 6z}$ into $\frac{\partial}{\partial z}$ of $x + 3y + 6z$ which, is 6 upon $x + 3y + 6z$. So, this is how we can find out $\frac{\partial f}{\partial x}$, $\frac{\partial f}{\partial y}$ or $\frac{\partial f}{\partial z}$ let us try one more problem based on this so, things should be more clear.

(Refer Slide Time: 21:55)

$$\begin{aligned}f(x, y, z) &= (x^2 + y^2 + z^2)^{-1/2} \\f_x &= -\frac{1}{2} (x^2 + y^2 + z^2)^{-1/2 - 1} \cdot \frac{\partial}{\partial x} (x^2 + y^2 + z^2) \\&= -\frac{2x}{2} (x^2 + y^2 + z^2)^{-3/2} = -x (x^2 + y^2 + z^2)^{-3/2} \\f_y &= -\frac{1}{2} (x^2 + y^2 + z^2)^{-1/2 - 1} \cdot (2y) = -y (x^2 + y^2 + z^2)^{-3/2} \\f_z &= -z (x^2 + y^2 + z^2)^{-3/2}\end{aligned}$$

So, it is $x^2 + y^2 + z^2$ whole is to power minus 1 by 2 so, f_x will be now it is t raise to power minus 1 by 2 that will be derivative of that will be minus 1 by 2 t which is $x^2 + y^2 + z^2$ and t minus 1 and del by del x of t again. That is $x^2 + y^2 + z^2$ which is equal to it is minus 2 x upon 2 its derivative of this is 2 x and it is $x^2 + y^2 + z^2$ whole raise to power minus 3 by 2, which is minus x into $x^2 + y^2 + z^2$ whole raise to power minus 3 by 2.

But similarly if you find $\frac{\partial f}{\partial y}$ it is again minus 1 by 2 $x^2 + y^2 + z^2$ whole raise to power minus 1 by 2 and del by del y of this term which is 2 y because x and z are independent of y . So, 2 2 cancel out and it is minus y into $x^2 + y^2 + z^2$ whole raise to power minus 3 by 2 and similarly f_z will be minus z into $x^2 + y^2 + z^2$ whole raise to power minus 3 by 2 so, this is how we can compute f_x , f_y or f_z .

(Refer Slide Time: 23:50)

$$f(x, y, z) = \sinh(xy - z^2)$$

$$f_x = \cosh(xy - z^2) \frac{\partial}{\partial x}(xy - z^2) = y \cosh(xy - z^2)$$

$$f_y = \cosh(xy - z^2) \frac{\partial}{\partial y}(xy - z^2) = x \cosh(xy - z^2)$$

$$f_z = \cosh(xy - z^2) \frac{\partial}{\partial z}(xy - z^2) = -2z \cosh(xy - z^2)$$

$$\sinh \theta = \frac{e^\theta - e^{-\theta}}{2}$$

$$\cosh \theta = \frac{e^\theta + e^{-\theta}}{2}$$

$$\frac{d}{d\theta}(\sinh \theta) = \cosh \theta$$

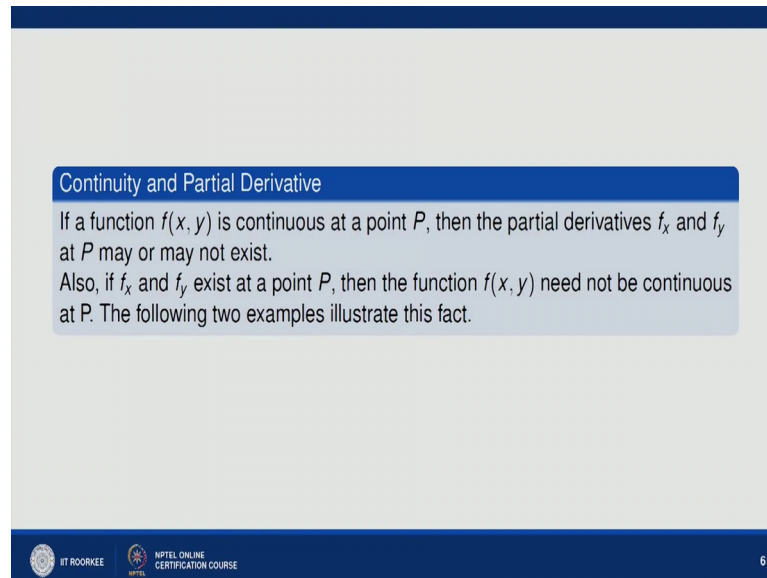

Now, suppose $f(x, y, z)$ is $\sinh(xy - z^2)$, what is \sinh hyperbolic theta? \sinh hyperbolic theta is e raised to power theta minus e raised to minus theta upon 2 and \cosh hyperbolic theta is e raised to power theta plus e raised to minus theta upon 2. So, we can easily see that $\frac{d}{d\theta}$ of \sinh hyperbolic theta is \cosh hyperbolic theta that we can easily see if we differentiate this respect to theta it is e raised to power theta, it will become plus e raised to power minus theta upon 2 which is \cosh hyperbolic theta that we can easily see.

So, if you take f_x which is $\frac{\partial f}{\partial x}$ now \sinh hyperbolic theta is \cosh hyperbolic theta the derivative of \sinh hyperbolic theta is \cosh hyperbolic theta and $\frac{\partial}{\partial x}$ of theta again it is $xy - z^2$ which is y into \cosh hyperbolic $xy - z^2$. Now, f_y is similarly, it is \cosh hyperbolic $xy - z^2$ into $\frac{\partial}{\partial y}$ of $xy - z^2$ which is again x times \cosh hyperbolic $xy - z^2$ and f_z will be \cosh hyperbolic $xy - z^2$ into $\frac{\partial}{\partial z}$ of $xy - z^2$ and derivative of this term respect to z partially this will be 0 then this will be minus $2z$ times \cosh hyperbolic $xy - z^2$. So, this is how we can compute f_x , f_y or f_z so, these are some simple illustrations.

Now, what is the relation between continuity and partial derivatives we have already seen, what do you mean by continuity of several variable functions and we have also seen partial derivatives of several variable functions. Now, in single variable function your

function is differentiable at a point so, this implies function will be continuous at that point we already know this result that if a function is of single variable and function is differentiable at a point so, this implies function is continuous at a point. A function is continuous at a point then the function may or may not be differentiable at that point. Now, what is a result in multivariable function let us see.

(Refer Slide Time: 27:03)

Continuity and Partial Derivative

If a function $f(x, y)$ is continuous at a point P , then the partial derivatives f_x and f_y at P may or may not exist.

Also, if f_x and f_y exist at a point P , then the function $f(x, y)$ need not be continuous at P . The following two examples illustrate this fact.

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 6

So, if a function $f(x, y)$ is continuous here function $f(x, y)$ is continuous at a point say P , then the partial derivative f_x and f_y at P may or may not exist. Also, if f_x and f_y exist at a point, then the function $f(x, y)$ need not be continuous at a point. So, your function partially derivative of a function f_x and f_y exists at a point then it also does not ensure that a function is continuous at that point.

In single variable function differentiability implies continuity, in several variable function is a function is a partial derivative exist a point it does not mean that a function is also continuous at that point how we can say this. So, we have counter examples let us see.

(Refer Slide Time: 28:03)

Handwritten mathematical proof on a whiteboard:

$$f(x, y) = \begin{cases} (x+y) \sin\left(\frac{1}{x+y}\right), & x+y \neq 0 \\ 0, & x+y = 0. \end{cases}$$

let $\epsilon > 0$ be given.

$$\lim_{(x,y) \rightarrow (0,0)} f(x,y) = f(0,0)$$

$$\Rightarrow \lim_{(x,y) \rightarrow (0,0)} (x+y) \sin\left(\frac{1}{x+y}\right) = 0.$$

$$\left| (x+y) \sin\left(\frac{1}{x+y}\right) - 0 \right| = |x+y| \left| \sin\frac{1}{x+y} \right| \leq |x+y| \cdot 1 \leq |x| + |y| < \delta + \delta$$

choose $2\delta = \epsilon$, then

$$\left| (x+y) \sin\frac{1}{x+y} - 0 \right| < \epsilon, \text{ whenever } 0 < |x| < \delta, 0 < |y| < \delta.$$

The first example for example is $f(x, y)$ was equal to it is x plus y sin of 1 upon x plus y x plus y should not equal to 0 and 0 when x plus y is equal to 0 . Now, first you will see your function is continuous at a point then its partial derivative does not exist at that point. This example which is continuous at a point 0 comma 0 , but partial derivative f_x and f_y does not exist at that point. So, for continuity what we have to show if the if we are saying that this function is continuous at origin so, what we have to prove. We have to prove that limit x, y tending to $0, 0$ $f(x, y)$ should be equals to $f(0, 0)$ or this means limit x, y tending to $0, 0$. Here $f(x, y)$ is x plus y sin 1 upon x plus y is equal to $f(0, 0)$ is 0 plus 0 is 0 means 0 .

So, this we have to show if we are saying that a function is continuous at a point 0 comma 0 or origin this means we have to prove this equation. Now, in order to prove this we have to use delta epsilon definition the only option is using delta epsilon definition. So, we will take again let epsilon greater than 0 be given. Now take mod of x plus y sin 1 upon x plus y minus 0 $f(x, y)$ minus 1 , this is equal to mod of x plus y into mod of sin 1 upon x plus y now, sin theta its mod is always less than or equal to 1 for any theta.

So, this will be less than or equals to mod x plus y into 1 and this is less than or equals to mod x plus mod y mod a plus b is always less than or equal to mod a plus mod b and if we take it less than delta plus delta. So, if we choose 2δ is equal to epsilon, then mod

of $x + y$ into \sin of 1 upon $x + y$ minus 0 is less than ϵ whenever $0 < |x + y| < \delta$ and $0 < |x| < \delta$ and $0 < |y| < \delta$.

So, we have shown the existence of such δ for every ϵ greater than 0 for which this inequality holds. Hence, we can say that the limit of this function is 0 or this equation holds this means function is continuous at origin. So, hence we can say that this function is continuous, now we have to find out its first order partial derivatives. Now, since function we cannot find its partial derivative as such we have to use the definition of limit because we have the function in the split form 0 at 0, 0 function has different value I mean 0 value.

(Refer Slide Time: 32:00)

$$f(x, y) = \begin{cases} (x+y) \sin\left(\frac{1}{x+y}\right), & x+y \neq 0 \\ 0, & x+y = 0. \end{cases}$$

$$f_x \Big|_{(0,0)} = \lim_{h \rightarrow 0} \frac{f(0+h, 0) - f(0,0)}{h} = \lim_{h \rightarrow 0} \frac{\cancel{h} \sin\left(\frac{1}{\cancel{h}}\right) - 0}{\cancel{h}} = \lim_{h \rightarrow 0} \sin\left(\frac{1}{h}\right) = \text{does not exist.}$$

$$f_y \Big|_{(0,0)} = \lim_{h \rightarrow 0} \frac{f(0, 0+h) - f(0,0)}{h} = \lim_{h \rightarrow 0} \frac{\cancel{h} \sin\left(\frac{1}{\cancel{h}}\right) - 0}{\cancel{h}} = \lim_{h \rightarrow 0} \sin\left(\frac{1}{h}\right) \rightarrow \text{does not exist.}$$

So, we have to use f_x at 0, 0 we have to use definition of limit h tending to 0 f of 0 plus h 0 minus f 0, 0 upon h by the definition of partial derivative of f with respect of x .

Now, this is limit h tending to 0 now f at h comma 0 we will use this thing which is h plus 0 is h into \sin 1 upon h minus f 0, 0 is 0 upon h , h cancels out. So, this is limit h tends to 0 \sin 1 by h and this is does not exist because it is not a finite value it I mean its not a unique value it lying between minus 1 and plus 1, but it is not unique. So, limit does not exist.

Similarly, if you if you find f_y at 0 comma 0 so, it is limit h tending to 0 f of 0 comma 0 plus h minus f 0, 0 upon h which is again limit h tending to 0. Now, f 0 comma h you say

you replace y by h and x by 0 so, it is again h sin 1 by h minus f 0, 0 is 0 upon h, h h cancels out and it is again limit h tends to 0 sin 1 by h which is does not exist. So, by this example we have seen there are if a function is continuous at a point it does not mean there is a first order partial derivative exist at that point ok.

- Show that the function

$$f(x, y) = \begin{cases} \frac{x^2 y}{x^4 + y^2}, & (x, y) \neq (0, 0), \\ 0, & (x, y) = (0, 0) \end{cases}$$

is not continuous at origin but its partial derivatives f_x and f_y exist at $(0, 0)$.

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 8

Now, another example now using this example you see the show that the function this is not continuous at origin, but its partial derivative f_x and f_y exists at origin. So, first we will prove this.

(Refer Slide Time: 34:43)

$$f(x, y) = \begin{cases} \frac{x^2 y}{x^4 + y^2}, & (x, y) \neq (0, 0) \\ 0, & (x, y) = (0, 0) \end{cases}$$

$\lim_{(x, y) \rightarrow (0, 0)} \frac{x^2 y}{x^4 + y^2}$

along $x=0$ $= 0$
 along $y=x^2$ $\lim_{x \rightarrow 0} \frac{x^2 \cdot x^2}{x^4 + x^4} = \lim_{x \rightarrow 0} \frac{x^4}{2x^4} = \frac{1}{2}$

does not exist
 $\Rightarrow f(x, y)$ is discontinuous at $(0, 0)$

So, it is x raise to power 4 y or it is x square sorry x square y upon x raise to power 4 plus y square when x, y is not equal to 0, 0 and it is 0 when x, y are 0 comma 0. Now first we have to show that this function is not continuous at origin. So, let us find this limit first limit x, y tend into 0, 0 function is x square y upon x raise to power 4 plus y square. Now, to prove that this limit does not exist we have to show that it is path dependent that is from two different paths if we have shown that the value of the limits are different this means limit does not exist.

Now, let us move along say along x equal to 0; that means, along y axis if you move along y axis then is simply substitute x equal to 0 here which is value is 0 so, it is equal to 0, if you put y x equal to 0 those value is simply 0. Now, you move along say y equal to x square now if you move along y equal to x square so, this will be limit x tending to 0 it is x square into x square upon x raise to power 4 plus x raise to power 4 which is equal to limit x tending to 0 x raise to power 4 upon $2x$ raise to power 4 which is 1 by 2.

So, we have show so, from this path from this path value is 0 and from this path value is 1 by 2 that is from two different paths values are different. This means that this limit does not exist and this implies $f(x, y)$ is discontinuous at origin ok.

(Refer Slide Time: 37:33)

$$f(x, y) = \begin{cases} \frac{x^2 y}{x^4 + y^2}, & (x, y) \neq (0, 0) \\ 0, & (x, y) = (0, 0) \end{cases}$$

$$f_x \Big|_{(0,0)} = \lim_{h \rightarrow 0} \frac{f(0+h, 0) - f(0,0)}{h} = \lim_{h \rightarrow 0} \frac{0 - 0}{h} = 0$$

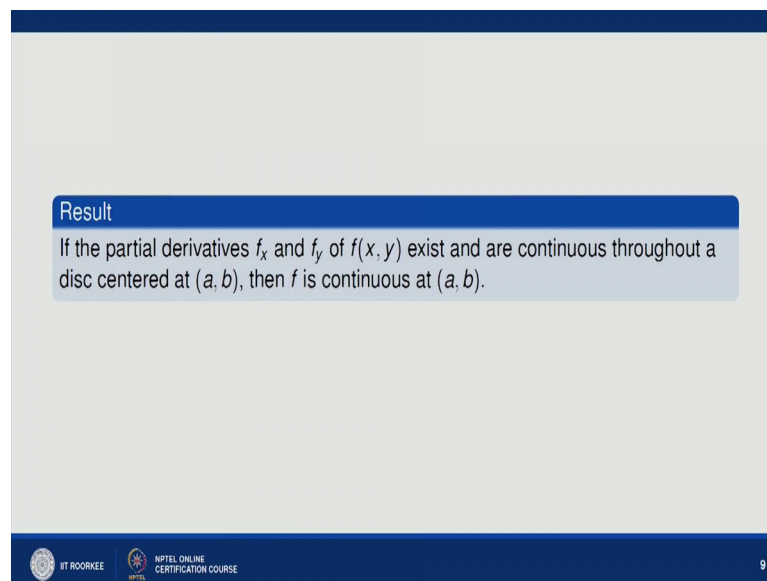

$$f_y \Big|_{(0,0)} = \lim_{h \rightarrow 0} \frac{f(0, 0+h) - f(0,0)}{h} = 0$$

Now, let us try to prove that first order partial derivative exist so, let us find f_x at 0 comma 0. Again we will use the definition of limit it is limit h tends to 0 f of 0 plus h comma 0 minus f 0, 0 upon h which is limit h tends to 0. Now, when you put h comma 0

here x is h y is 0 as x is h y is 0 so, simply this value will be 0 . So, it is 0 minus 0 as 0 0 is 0 upon h which is 0 now again when you compute f_y at 0 comma 0 , it is limit h tends to 0 f of 0 comma 0 plus h minus f 0 , 0 upon h which is again equal to limit h tending to 0 it is 0 comma h you replace x by 0 y by h x by 0 y by h . So, this value will be 0 , 0 minus 0 upon h it is again 0 . So, f_x and f_y exist at origin which is 0 value is 0 , but we have seen that this function is not continuous at origin.

So, existence of partial derivative at a point does not guarantee that a function is continuous at that point also for several variable functions. So, what is the additional condition required when we can say that beside existing of partial derivative what is what are the additional condition which function must have so that we can say that the function is continuous at that point also.

(Refer Slide Time: 39:37)

So, that condition is basically if the partial derivative f_x and f_y of $f(x, y)$ exist and are continuous also throughout a disk centred at a comma b , then function is continuous at that point; that means, beside the existence of partial derivative at a point. We must have continuity of partial derivative throughout a disk centred at that point, then we can say function is continuous at that point.

Thank you very much.
