Lecture - 06
Partial Derivatives-II

Hello friends. So, welcome to lecture series on multivariable calculus. So, in the last lecture we have seen what is mean by a partial derivative of multivariable functions ok. So now, we will see second or higher order partial derivatives. So, what do you mean by this let us see. So, again suppose z equal to $f(x, y)$.

(Refer Slide Time: 00:41)

$$\begin{aligned} \frac{\partial^2 f}{\partial y^2} \bigg|_{(a,b)} &= \frac{\partial}{\partial y} \left(\frac{\partial f}{\partial y} \right) \bigg|_{(a,b)} \\ &= f_{yy} \bigg|_{(a,b)} \\ &= \lim_{h \rightarrow 0} \frac{f_y(a, b+h) - f_y(a, b)}{h} \end{aligned}$$

$$Z = f(x, y)$$

$$f_x \bigg|_{(a,b)} = \lim_{h \rightarrow 0} \frac{f(a+h, b) - f(a, b)}{h}$$

$$f_y \bigg|_{(a,b)} = \lim_{h \rightarrow 0} \frac{f(a, b+h) - f(a, b)}{h}$$

$$\frac{\partial^2 f}{\partial x^2} \bigg|_{(a,b)} = f_{xx} \bigg|_{(a,b)} = \lim_{h \rightarrow 0} \frac{f_x(a+h, b) - f_x(a, b)}{h}$$

$$\frac{\partial f_x}{\partial x} \bigg|_{(a,b)}$$

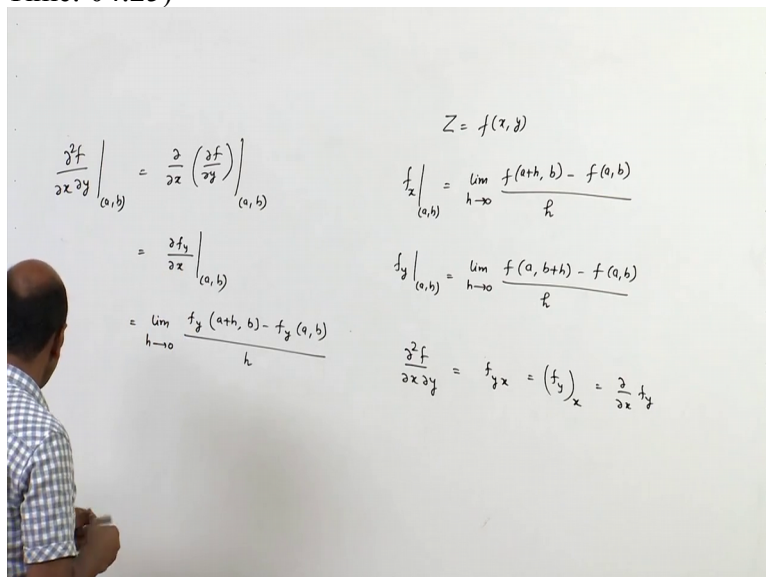

Where x and y are independent variables and z is a dependent variable. Now, we have seen we have already seen what do you mean by f_x at a point say a comma b it is simply $\frac{\partial f}{\partial x}$, which is $\lim_{h \rightarrow 0} \frac{f(a+h, b) - f(a, b)}{h}$. And similarly, f_y at a comma b is equals to $\lim_{h \rightarrow 0} \frac{f(a, b+h) - f(a, b)}{h}$.

Now, suppose we define $\frac{\partial^2 f}{\partial x^2}$ at a point a comma b . Similarly, as we define second order derivative for single variable functions, $f''(x)$ here, we define second order partial derivative of f respect to x , it is also denoted by f_{xx} . So, at a point suppose we are defining it at a point a comma b , at a point a comma b it is simply $\lim_{h \rightarrow 0} \frac{f_x(a+h, b) - f_x(a, b)}{h}$ because, what does it mean basically? It means $\frac{\partial f_x}{\partial x}$ or at a comma b it means $\frac{\partial}{\partial x} \left(\frac{\partial f}{\partial x} \right)$; that means, now you have to take f_x a new function

and you have to apply the definition of del upon del x in f x. So, we have applied definition of del by del x in f x as f x a plus h minus b; f x of a comma b minus upon h, we simply replace f by f x in this definition so that we can get del square f upon del x square.

Now, similarly if we define in del square f upon del y square, that is second order partial derivative of f respect to y at say a comma b, which is can be defined as del by del y of del f upon del y at a comma b or also denoted by f y y at a comma b is simply given by limit h tending to 0; f of f y of because now, you have to apply the definition of del of del upon del y on f y ok, and del upon and f definition of f y is this. So, you have to simply replace f by f y here so; that means, f y of a comma b plus h minus f y of a comma b upon h.

So, this is how we can define second order partial derivative of f respect to x or respect to y. Now, come to mix order partial derivatives mixed order mixed second order partial derivative of f respect to x or y. Now, suppose you want to define del square f upon del x del y at say a comma b; it is del by del x of del f upon del y at a comma b or we can say, it is f del of f y of del f upon del x at a comma b. (Refer Slide Time: 04:25)

$$\begin{aligned} \frac{\partial^2 f}{\partial x \partial y} \bigg|_{(a,b)} &= \frac{\partial}{\partial x} \left(\frac{\partial f}{\partial y} \right) \bigg|_{(a,b)} \\ &= \frac{\partial f_y}{\partial x} \bigg|_{(a,b)} \\ &= \lim_{h \rightarrow 0} \frac{f_y(a+h, b) - f_y(a, b)}{h} \end{aligned}$$

$$Z = f(x, y)$$

$$f_x \bigg|_{(a,b)} = \lim_{h \rightarrow 0} \frac{f(a+h, b) - f(a, b)}{h}$$

$$f_y \bigg|_{(a,b)} = \lim_{h \rightarrow 0} \frac{f(a, b+h) - f(a, b)}{h}$$

$$\frac{\partial^2 f}{\partial x \partial y} = f_{yx} = \left(f_y \right)_x = \frac{\partial}{\partial x} f_y$$

So, this is by definition we have to replace f by f y here, within this definition because, it is del f upon del x and instead of f we are now having f y. So, that will be limit h tending to 0 f y of a plus h comma b minus f y of a comma b upon h.

Now, this mixed order second order mixed partial derivative can also be represented it as f of y x because, it is what? It is f y respect to x; that means, del upon del x of f y; that means, I differentiate partially this function respect to x, that is del upon del x

of f_y which is same, which is same which is here. So, we can also represent this partial derivative as f_{yx} .

Now, the second one is del square f upon del by del x , which is at a comma b which is also represented as del by del y of del f upon del x at say a comma b or it is f of x_y at a comma b .

(Refer Slide Time: 06:14)

$$\left. \frac{\partial^2 f}{\partial y \partial x} \right|_{(a,b)} = \left. \frac{\partial}{\partial y} \left(\frac{\partial f}{\partial x} \right) \right|_{(a,b)}$$

$$= (f_{xz})_{(a,b)}$$

$$= \lim_{h \rightarrow 0} \frac{f_x(a, b+h) - f_x(a, b)}{h}$$

$$Z = f(x, y)$$

$$f_x \Big|_{(a,b)} = \lim_{h \rightarrow 0} \frac{f(a+h, b) - f(a, b)}{h}$$

$$f_y \Big|_{(a,b)} = \lim_{h \rightarrow 0} \frac{f(a, b+h) - f(a, b)}{h}$$

It is by the definition we can write it like this, it is limit x tending to 0. Now, you have to you have to apply the definition of del upon del y on f_x . So, it is f_x at a comma b plus h minus f_x of f_x at a comma b upon h . So, this is how, we can define f_{xy} or f_{yx} .

(Refer Slide Time: 07:15)

Continued...

- $\frac{\partial^2 f}{\partial y \partial x} = \frac{\partial}{\partial y} \left(\frac{\partial f}{\partial x} \right)$ or $\frac{\partial f_x}{\partial y}$
Denoted by f_{xy} or $(f_x)_y$.
 $(f_{xy})_{(a,b)} = \lim_{h \rightarrow 0} \frac{f_x(a, b+h) - f_x(a, b)}{h}$
- $\frac{\partial^2 f}{\partial y^2} = \frac{\partial}{\partial y} \left(\frac{\partial f}{\partial y} \right)$ or $\frac{\partial f_y}{\partial y}$
Denoted by f_{yy} .
 $(f_{yy})_{(a,b)} = \lim_{h \rightarrow 0} \frac{f_y(a, b+h) - f_y(a, b)}{h}$

f_{xy} and f_{yx} are also called mixed second-order partial derivatives.

So, f_{xy} or f_{yx} are also called mixed second order partial derivative. Now, let us try some problems based on this. So, these are all second order partial derivatives respect to x or y .

(Refer Slide Time: 07:31)

$$\begin{aligned}
 f &= (2x - 3y)^3 \\
 f_x &= 3(2x - 3y)^2 \cdot \frac{\partial}{\partial x}(2x - 3y) = 6(2x - 3y)^2 \\
 f_y &= 3(2x - 3y)^2 \cdot \frac{\partial}{\partial y}(2x - 3y) = -9(2x - 3y)^2 \\
 f_{xx} &= \frac{\partial}{\partial x} f_x = 6 \times 2 \times (2x - 3y)^1 \cdot \frac{\partial}{\partial x}(2x - 3y) = 24(2x - 3y) \\
 f_{yy} &= \frac{\partial}{\partial y} f_y = -18(2x - 3y) \cdot \frac{\partial}{\partial y}(2x - 3y) = -54(2x - 3y) \\
 f_{xy} &= (f_x)_y = \frac{\partial}{\partial y} f_x = 12(2x - 3y) \cdot \frac{\partial}{\partial y}(2x - 3y) = -36(2x - 3y) \\
 f_{yx} &= (f_y)_x = \frac{\partial}{\partial x} f_y = -18(2x - 3y) \cdot \frac{\partial}{\partial x}(2x - 3y) = -36(2x - 3y)
 \end{aligned}$$

Now, suppose f is $2x - 3y$ whole cube. Now, what is f_x ? it is t^3 cube t cube is $3t^2$ square and $\frac{\partial}{\partial x}$ of t again which is which is 2 here, and 2 into 3 is 6 a 6 times $2x - 3y$ whole square, and again f_y is similarly it is $3t^2$ square t is $2x - 3y$ and it is $\frac{\partial}{\partial y}$ of t again, which is -3 minus 3 into 3 is -9 minus 9 $2x - 3y$ whole square. Now, suppose you want to compute f_{xx} f_x is means, $\frac{\partial}{\partial x}$ of f_x .

Now, $\frac{\partial}{\partial x}$ of f_x is you have to differentiate f_x respect to x again partially. So, when you differentiate this partial respect to again. So, what we will obtain this is again 6 into t^2 square, which is 6 into 2×2 into $2x - 3y$ this for 1 into $\frac{\partial}{\partial x}$ of t again, which is 2 , 6 into 4 is 24 , 24 $2x - 3y$. Now, if you want to compute f_{yy} , which is $\frac{\partial}{\partial y}$ of f_y and it is differentiate this function respect partial respect to y .

So, it is it is -18 $2x - 3y$ and $\frac{\partial}{\partial y}$ of t again. So, that will be 54 times $2x - 3y$ ok. Now, suppose you want to compute f_{xy} , which is f_x of y ok; that means, $\frac{\partial}{\partial y}$ of f_x ok. So, $\frac{\partial}{\partial y}$ of f_x this is f_x the $\frac{\partial}{\partial y}$ of this function, that is differentiate this partial respect to y and; that means, it is 12 $2x - 3y$ $\frac{\partial}{\partial y}$ of this again respect to y , that is -3 into 12 is -36 times $2x - 3y$.

Now, f_y x suppose f_y x f_y respect to x , that is $\frac{\partial}{\partial x}$ of f_y ; that means, it is f_y you have to differentiate this partial respect to x ; that means, minus 18 $2x$ minus $3y$ $\frac{\partial}{\partial y}$ of or $\frac{\partial}{\partial x}$ of this function $2x$ minus $3y$, which is 30 minus 36 times $2x$ minus $3y$. So, that is how we can compute second order partial derivatives respect to x or y ok. Now, see this again say second problem.

(Refer Slide Time: 11:38)

Handwritten mathematical derivations for the partial derivatives of $f = \frac{x}{x^2 + y^2}$, where $(x, y) \neq (0, 0)$.

First, the first partial derivative with respect to x is calculated using the quotient rule:

$$f_x = \frac{\frac{\partial}{\partial x} x \cdot (x^2 + y^2) - x \cdot \frac{\partial}{\partial x} (x^2 + y^2)}{(x^2 + y^2)^2}$$

$$= \frac{(x^2 + y^2) \cdot 1 - x \cdot 2x}{(x^2 + y^2)^2}$$

$$= \frac{y^2 - x^2}{(x^2 + y^2)^2}$$

Next, the second partial derivative f_{xx} is calculated by differentiating f_x with respect to x :

$$f_{xx} = \frac{\partial}{\partial x} f_x = \frac{(y^2 - x^2) \cdot (-2x) - (x^2 + y^2) \cdot 2x}{(x^2 + y^2)^4}$$

$$= \frac{-2x(y^2 - x^2) - 2x(x^2 + y^2)}{(x^2 + y^2)^4}$$

$$= \frac{-2x(y^2 - x^2 + x^2 + y^2)}{(x^2 + y^2)^4}$$

$$= \frac{-2x(2y^2)}{(x^2 + y^2)^4}$$

$$= \frac{-4xy^2}{(x^2 + y^2)^4}$$

Similarly, the first partial derivative with respect to y is calculated:

$$f_y = \frac{\frac{\partial}{\partial y} x \cdot (x^2 + y^2) - x \cdot \frac{\partial}{\partial y} (x^2 + y^2)}{(x^2 + y^2)^2}$$

$$= \frac{x \cdot 2y - x \cdot (x^2 + y^2) \cdot \frac{1}{y}}{(x^2 + y^2)^2}$$

$$= \frac{2xy - x(x^2 + y^2)}{(x^2 + y^2)^2}$$

$$= \frac{2xy - x^3 - xy^2}{(x^2 + y^2)^2}$$

$$= \frac{-x^3 + 2xy - xy^2}{(x^2 + y^2)^2}$$

So, what a second problem now, it is f equal to x upon x square plus y square and x y should not equal to 0 0 because, there is a problem in 0 0 . So, we are excluding 0 0 from the domain. Now, what is f_x ? First you compute f_x f_x is. Now, x is a numerator x is a denominator also. So, we have to apply quotient rule, that is denominator derivative of numerator minus numerator derivative of denominator, that is $2x$ upon denominator whole square.

So, this will be equals to y square minus x square upon x square plus y square whole square ok. Now, what is f_y ? Now, it is x constant for this partial derivative of f is respect to y . So, we take x into $\frac{\partial}{\partial y}$ of 1 upon x square plus y square. So, it is x into 1 by t , that is minus 1 by t square. So, it is minus 1 upon t square then t again, that is $\frac{\partial}{\partial y}$ of t and this is $2xy$ upon x square plus y square whole square and with negative sign. So, this is $\frac{\partial f}{\partial y}$ ok.

Now, you want to compute second order partial derivatives again we can use this thing f_{xx} , which is $\frac{\partial}{\partial x}$ of f_x we have to differentiate this again respect to x ok. So, it is denominator as it is derivative of numerator, which is minus $2x$ minus

numerator derivative of denominator it is 2 times x square plus y square and it again upon denominator whole square ok.

So, this will be minus 2 x x square plus y square and it is x square y square 1 is cancelled out it is minus 2 x of square y square and it is minus 4 x y square minus x square upon x square plus y square whole cube ok, and it is it is equals to it is minus 2 x cube it is plus 4 x cube. So, it is 2 x cube and it is minus 2 x y square, it is minus 4 x that is minus 6 x y square upon x square plus y square whole square whole cube. Similarly, we can find f_{yy} also.

(Refer Slide Time: 15:08)

$$f = \frac{x}{x^2+y^2}, \quad (x, y) \neq (0, 0)$$

$$f_{xy} = \left(\frac{f_x}{y} \right) = \frac{\frac{\partial}{\partial y} f_x}{y}$$

$$= \frac{(x^2+y^2)^2 (2y) - (y^2-x^2) 2(x^2+y^2) 2y}{(x^2+y^2)^4}$$

$$= \frac{2y(x^2+y^2) - 4y(y^2-x^2)}{(x^2+y^2)^3}$$

$$= \frac{-2y^3 + 6yx^2}{(x^2+y^2)^3}$$

$$f_x = \frac{(x^2+y^2) \cdot 1 - x \cdot 2x}{(x^2+y^2)^2}$$

$$= \frac{y^2 - x^2}{(x^2+y^2)^2}$$

$$f_y = x \cdot \frac{\partial}{\partial y} \left(\frac{1}{x^2+y^2} \right)$$

$$= x \cdot \left(\frac{-1}{(x^2+y^2)^2} \right) \cdot \frac{\partial}{\partial y} (x^2+y^2)$$

$$= \frac{-2xy}{(x^2+y^2)^2}$$

Now, let us compute one more term here, it is one of the mixed derivative anyone say we compute f_{xy} f_{yx} is f_{xy} that is, del by del y of f_x that is simply means, you have to differentiate this partial respect to y. So, again denominator as it is derivative of numerator minus numerator derivative of denominator 2 t t again that is 2 y upon denominator whole square. So, this is further equal to cancel a, so square y square from numerator and denominator.

So, we will obtain 2 y into x square plus y square and it is minus 4 y y square minus x square upon x square plus y square whole cube. So, this is 2 y cube minus 4 y cube, that is minus 2 y cube and it is 2 y x square it is minus plus 4 y x square, that is plus 6 y x square upon x square plus y square whole cube. And similarly, we can find f_{yx} f_{xy} x. So, that is how we can find f_{xx} f_{yy} f_{xy} or f_{yx} .

(Refer Slide Time: 16:35)

Problems:

- 1 Evaluate f_{xx} , f_{xy} , f_{yx} and f_{yy} in the following
 - $f(x, y) = (2x - 3y)^3$.
 - $f(x, y) = \frac{x}{x^2 + y^2}$, $(x, y) \neq (0, 0)$.
 - $f(x, y) = e^{-x} \sin(x + y)$.
- 2 Evaluate f_{xx} , f_{yy} , f_{zz} , f_{xy} , f_{yz} , f_{zx} of the function $f(x, y, z) = x^x y^y z^z$, $(x, y, z) \neq (0, 0, 0)$.
- 3 Prove that the function $f(x, y, z) = e^{3x+4y} \cos 5z$, satisfy the equation $f_{xx} + f_{yy} + f_{zz} = 0$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 4

Now, let us solve one problem of 3 variables. Now, suppose $f(x, y, z)$ is x raised to power x , y raised to power y , z raised to power z . We are x and y and z are non-negative.

(Refer Slide Time: 16:46)

$$\begin{aligned}
 f_{xx} &= \frac{\partial}{\partial x} f_x \\
 &= f \left[\frac{1}{x} \right] + (1 + \log x) f_x \\
 &= \frac{f}{x} + f (1 + \log x)^2 \\
 f_{yy} &= \frac{f}{y} + f (1 + \log y)^2 \\
 f_{zz} &= \frac{f}{z} + f (1 + \log z)^2
 \end{aligned}$$

$$\begin{aligned}
 f_{xz} &= \left(\frac{f_x}{z} \right) \\
 &= \frac{\partial}{\partial z} f_x = (1 + \log x) \frac{f_x}{z} = f (1 + \log x) (1 + \log z) \\
 f_{yz} &= f (1 + \log y) (1 + \log z) \\
 f_{xy} &= f (1 + \log x) (1 + \log y)
 \end{aligned}$$

$$\begin{aligned}
 \Rightarrow f_x &= f [1 + \log x] \\
 f_y &= f [1 + \log y] \\
 f_z &= f [1 + \log z]
 \end{aligned}$$

Now, you have to find here you have to find f_{xx} all second order partial derivatives for this function. So, how will you compute f_x . So, you have to take log first. So, log of f will be equals to $x \log x$ plus $y \log y$ plus $z \log z$. Now, differentiate this equation partially respect to x . So, log t that is 1 upon t and t again, that is f_x . Now here, both are function of x . So, you apply product rule first as it is derivative second plus second as it is derivative of first and these two are independent of x . So, derivative will be 0 partial derivative will be 0 .

So, this implies f_x will be f into $1 + \log x$ of course, it is base e . Now, similarly f_y will be f into $1 + \log y$ and f_z will be f into $1 + \log z$. Now, suppose you want to compute $x x x$; $f_x x x$. So, how can you compute this? It is $\frac{\partial}{\partial x}$ of f_x which is so, so you have to differentiate this again respect to x . So, this is also a function of x and this is also a function of x . So, you have to apply product rule. So, f first as it is, derivative of second plus second as it is, derivative of first f_x and what is f_x ? what is f_x ? f_x is this.

So, it is f into $1 + \log x$. So, this is $f_x x$. Now, similarly $f_y y$ will be because, it is symmetrical in x, y and z . So, we can simply write $f_y y$ as f upon y f $1 + \log y$ whole square $f_z z$ as f upon z plus f plus $1 + \log z$ whole square ok. Now, suppose you want to find out f suppose $x f_x z$ that is f_x at z , that is $\frac{\partial}{\partial z}$ of f_x . Now, what is $f_x f_x$ is this and you have to differentiate this f_x respect to z partially. Now, this is independent of z because, x, y, z are independent of each other independent variables ok.

So, it is $1 + \log x$ you can take outside and this is the function of x, y, z . So, partial derivative of respect to z will be f_z and f_z is f $1 + \log z$. So, it is f $1 + \log z \log x$ into $1 + \log z$. So, again using a symmetry we can simply say that, $f_y z$ will be f into $1 + \log y$ into $1 + \log z$ and similarly, $f_x y$ will be f $1 + \log x$ into $1 + \log y$ ok. So, that is how we can find out all other all mixed second order partial derivative for this function. Now, the next problem proved at the function this satisfy this equation. So, again this is a simple problem let us see how can we.

(Refer Slide Time: 21:32)

$$f = e^{3x+4y} \cos 5z$$

$$f_x = \left(e^{3x+4y} \cos 5z \right) \frac{\partial}{\partial x} (3x+4y) = 3 e^{3x+4y} \cos 5z$$

$$f_{xx} = 9 e^{3x+4y} \cos 5z \quad \text{--- (1)}$$

$$f_y = 4 e^{3x+4y} \cos 5z \Rightarrow f_{yy} = 16 e^{3x+4y} \cos 5z \quad \text{--- (2)}$$

$$f_z = e^{3x+4y} (-\sin 5z) \times 5 \Rightarrow f_{zz} = -25 e^{3x+4y} \cos 5z \quad \text{--- (3)}$$

$$\text{(1) + (2) + (3)} \Rightarrow f_{xx} + f_{yy} + f_{zz} = 0$$

So, show this what is f here? F is e raised to power $3x + 4y$ and $\cos 5z$ ok. Now, what is f_x now, it is e raised to power t . So, e raised to power t is e raised to power t derivative $\cos 5z$ remain as it is and t again that is $\frac{d}{dx}$ of t again that is $3x + 4y$, which is 3 times e raised to power $3x + 4y$ into $\cos 5z$ ok. Now, what is f_{xx} ? the derivative of this again partial derivative of this again respect to x . So, that will be $9e$ raised to power $3x + 4y$ $\cos 5z$ this is one.

Now, compute f_{yy} f_y is $4e$ raised to power $3x + 4y$ into $\cos 5z$ we can directly see, derivative of e raised to power t is e raised to power t and t again, which is $4\cos 5z$ remain as it is. So, it is $4e$ raised to power $3x + 4y$ into $\cos 5z$. Now, this implies f_{yy} will be now, differentiate this again partially respect to y . So, what we would obtain this is $16e$ raised to power $3x + 4y$ $\cos 5z$.

So, this is second equation. Now, what is f_z ? f_z is now, this is free from z remain as it is $\cos t$ is minus $\sin t$ and t again, which is 5 and this implies f_z will be now, differentiate this again partial respect to z . So, what we will obtain this is 5 into 5 is 20 minus 25 it is e raised to power $3x + 4y$ into $\cos 5z$ because, derivative of \sin is \cos .

So, this is third equation. Now, when you add when you add 1 2 and 3. So, what we would obtain we will obtain $f_{xx} + f_{yy} + f_{zz}$ in the left-hand side and the right-hand side this is same and 16 plus 9 is 25 minus 25 is 0 . So, this is equal to 0 . So, hence we have proved. So, this equation is basically called Laplace equation, this equation we call as Laplace equation. So, we can say that this function e raised to power $3x + 4y$ into $\cos 5z$ satisfy a Laplace equation now, what can we say about mixed second order partial derivatives, that is f_{xy} or f_{yx} are they always same or there should be some condition on function f . So, that we can say, that they are equal at some point.

(Refer Slide Time: 25:05)

$$f(x, y) = \begin{cases} \frac{xy(x^2 - y^2)}{(x^2 + y^2)} & (x, y) \neq (0, 0) \\ 0 & (x, y) = (0, 0) \end{cases}$$

$$f_x|_{(0,0)} = \lim_{h \rightarrow 0} \frac{f(0+h, 0) - f(0,0)}{h} = 0$$

$$f_x|_{(0,h)} = \lim_{k \rightarrow 0} \frac{f(0+k, h) - f(0, h)}{k} = \lim_{k \rightarrow 0} \frac{hk(k^2 - h^2)}{(k^2 + h^2)} = 0$$

$$f_{xy}|_{(0,0)} = \lim_{h \rightarrow 0} \frac{f_x(0, h) - f_x(0, 0)}{h} = \lim_{h \rightarrow 0} \frac{0 - 0}{h} = 0$$

$$f_{yx}|_{(0,0)} = \lim_{h \rightarrow 0} \frac{f_y(0, h) - f_y(0, 0)}{h} = \lim_{h \rightarrow 0} \frac{-h^3/h^2 - 0}{h} = -h = 0$$

So, let us discuss this example example is $f(x, y)$ is equals to $xy(x^2 - y^2)$ square upon $x^2 + y^2$ $xy \neq 0$ and 0 when xy is equal to 0 ok, let us discuss this example. So, things will be clear after setting this example. So, let us compute f_x at origin and f_y at origin for this particular problem ok.

So, what is f_x at origin? It is f_x at origin is f_x at y at origin, that is $\frac{\partial}{\partial y} f_x$ at origin and that is $\lim_{h \rightarrow 0} \frac{f_x(0, h) - f_x(0, 0)}{h}$. So, what it is it is $\lim_{h \rightarrow 0} \frac{f_x(0, h) - f_x(0, 0)}{h}$. So, this is f_{xy} at $(0, 0)$. Now similarly, what is f_y at $(0, 0)$ it is f_y at x at origin, which is $\frac{\partial}{\partial x} f_y$ at $(0, 0)$; that means, it is $\lim_{h \rightarrow 0} \frac{f_y(h, 0) - f_y(0, 0)}{h}$.

So, first we will compute f_x at $(0, h)$ f_x at $(0, 0)$ and f_y at this then, we can compute f_{xy} or f_{yx} at $(0, 0)$. So, what is f_x at $(0, 0)$ it is $\lim_{h \rightarrow 0} \frac{f_x(0, h) - f_x(0, 0)}{h}$. So, it is now, you take x as h y as 0 when you take x as h y as 0 y as 0 . So, this will be simply 0 and $f_x(0, 0)$ is 0 . So, $0 - 0$ is 0 . So, this value is simply 0 . Now, you compute f_x at $(0, h)$ we we need now, we need f_x at $(0, h)$ ok. Now, this is say now take $\lim_{k \rightarrow 0}$ because, h is already here.

So, it is $f(0, k) - f(0, h)$ upon k ok, at $(0, h)$. Now, you replace x by k and y by h . So, what we will obtain $\lim_{k \rightarrow 0} \frac{f(0, k) - f(0, h)}{k}$ it is h k into $k^2 - h^2$ upon $k^2 + h^2$ minus 0 h is when

you substitute x as 0 y as h. So, it is 0 whole divided by k. So, this k will cancel with this k and when you take k tending to 0 here.

So, it will be it will be, it will be minus when you take a tend to 0 it is minus h cube upon h square, which is minus h. So, so what we can say about f x y at 0 comma 0 now you can substitute it over here, f x at 0 comma h is minus h you can substitute this value as minus h f x at 0 comma 0 is 0. So, it is 0 upon h.

(Refer Slide Time: 30:03)

$$f(x,y) = \begin{cases} \frac{xy(x^2-y^2)}{(x^2+y^2)}, & (x,y) \neq (0,0) \\ 0, & (x,y) = (0,0) \end{cases}$$

$$f_y(0,0) = \lim_{h \rightarrow 0} \frac{f(0,0+h) - f(0,0)}{h} = 0$$

$$f_y|_{(h,0)} = \lim_{k \rightarrow 0} \frac{f(h,0+k) - f(h,0)}{k} = \lim_{k \rightarrow 0} \frac{\frac{hk(h^2-k^2)}{h^2+k^2} - 0}{k} = \frac{h^3}{h^2} = h$$

$$f_{xy}|_{(0,0)} = \lim_{h \rightarrow 0} \frac{f_x(0,0+h) - f_x(0,0)}{h} = -1$$

$$f_{xy}|_{(0,0)} = \left(\frac{\partial f_x}{\partial y} \right)_{(0,0)} = \left(\frac{\partial}{\partial y} \frac{xy(x^2-y^2)}{(x^2+y^2)} \right)_{(0,0)}$$

$$= \lim_{h \rightarrow 0} \frac{f_x(0,0+h) - f_x(0,0)}{h} = \lim_{h \rightarrow 0} \frac{f_x(0,h) - f_x(0,0)}{h}$$

$$\left(\frac{\partial f_x}{\partial y} \right)_{(0,0)} = \left(\frac{\partial f_y}{\partial x} \right)_{(0,0)} = \frac{\partial}{\partial x} f_y|_{(0,0)} = \lim_{h \rightarrow 0} \frac{f_y(0+h,0) - f_y(0,0)}{h} = \lim_{h \rightarrow 0} \frac{h - 0}{h} = 1$$

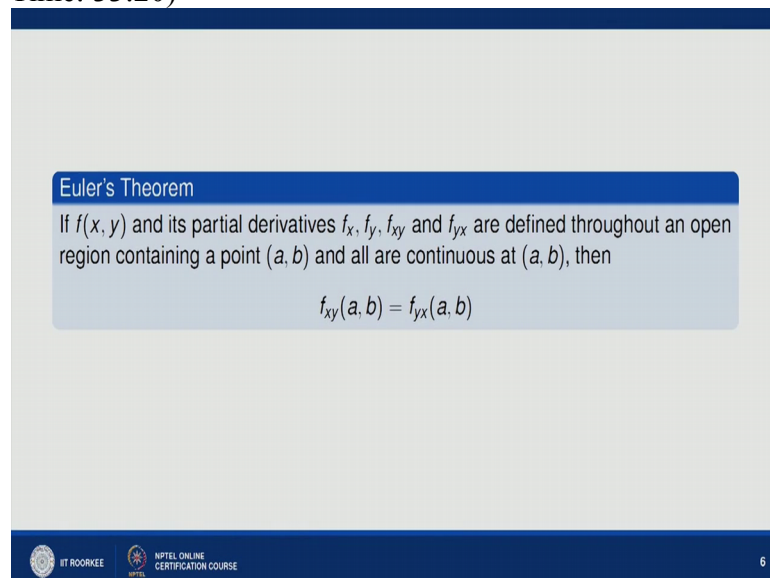

So, this expression will be limitation to 0 minus h minus 0 upon h, which is minus 1. So, so we can say, that this value at 0 comma 0 is minus 1. Now similarly, we try to compute f y x at 0 comma 0. Now, what is f y at 0 comma 0 it is limit h tending to 0 f at 0 comma 0 plus h minus f 0 0 upon h now, again when you take x as 0 y as h ok. So, it will be 0 and f 0 0 is 0. So, this value is 0. Now, when you take f y at say 0 comma h h comma 0 you see, we need f y at h comma 0.

So, f y at h comma 0 is limit k tending to 0 f at we need f y; that means, we have to change y only remaining x has remained fixed 0 comma h comma 0 plus k minus f at h comma 0 divided by k. Now, this is limit k tending to 0 now here, you replace x by h and y by k. So, it is h k. So, it is h k into h square minus k square upon h square plus k square this minus f at h comma 0 x is h y is 0 when you take y as 0. So, this expression is 0. So, it is 0 upon k. So, this k will cancel with this k and when you take k tending to 0. So, k will be 0. So, it is h cube upon h square which is h.

So, what can we say about f_{yx} ? So, this will be equal to now here limit h tending to 0 what is f_y at h comma 0 it is h . So, it is h minus f_y at 0 comma 0 is 0. So, it is 0 upon h . So, this value is 1. So, what do we conclude from here. So, we have concluded that, f_{yx} at some point may not be equal to f_{xy} it is 1 it is minus 1 for some function $f(x, y)$ may not be equal to f_{yx} .

So, what is the additional condition required on f . So, that we can say, that the mixed second order partial derivatives are equal ok. So, that condition is basically we have Euler's theorem, which states that if the function $f(x, y)$ and its partial derivatives f_x , f_y , f_{xy} and f_{yx} are defined throughout an open region containing a point a comma b and all are continuous at a comma b then, only we can say that f_{xy} is equals to f_{yx} otherwise they may not be equal ok.

Euler's Theorem

If $f(x, y)$ and its partial derivatives f_x , f_y , f_{xy} and f_{yx} are defined throughout an open region containing a point (a, b) and all are continuous at (a, b) , then

$$f_{xy}(a, b) = f_{yx}(a, b)$$

Handwritten mathematical derivations on a whiteboard:

$$z = f(x, y)$$

$$\frac{\partial^4 f}{\partial x^4} = f_{xxxx}$$

$$\frac{\partial^3 f}{\partial x^2 \partial y} = \frac{\partial^2}{\partial x^2} \left(\frac{\partial f}{\partial y} \right)$$

$$= \frac{\partial}{\partial x} \left(\frac{\partial^2 f}{\partial x \partial y} \right) = \frac{\partial}{\partial x} (f_{yx})$$

$$= (f_{yx})_x$$

$$\frac{\partial^3 f}{\partial y^3} = f_{yyy}$$

Dr. S. K. Gupta

So, this is all about second or partial derivatives. Now, we can define higher order partial derivative also like, suppose z equal to $f(x, y)$ the function of x or y . So, we can define say 4th order partial derivative also with respect to x , which is f_{xxxx} we can also define say $\frac{\partial^3 f}{\partial x^2 \partial y}$, which is simply $\frac{\partial^2}{\partial x^2}$ of $\frac{\partial f}{\partial y}$ or $\frac{\partial}{\partial x}$ of $\frac{\partial^2 f}{\partial x \partial y}$; that means, $\frac{\partial}{\partial x}$ of f it is f_y or $\frac{\partial}{\partial y}$ of f is f_y .

So, these are all representation of the same expression basically similarly, we may have any higher derivatives suppose $\frac{\partial^3 f}{\partial y^3}$, which is f_{yyy} and so on. So, similarly we can compute these values also for any function f so.

Thank you very much.
