Lecture - 23
Stability of Linear Systems -II

Hello friends welcome to my lecture on stability of linear systems. We begin with an example on a system of linear linear system $dx/dt=2x-7y$, $dy/dt=3x-8y$.

(Refer Slide Time: 00:49)

Example: Let us consider

$$\frac{dx}{dt} = 2x - 7y, \quad \frac{dy}{dt} = 3x - 8y.$$

$$a=2, b=-7, \\ c=3, d=-8$$

Then Eigen values are $\lambda = -5, -1$.

The roots are **real unequal and of the same sign**.

\Rightarrow the critical point $(0,0)$ is a **node** and it is **asymptotically stable**.

Here if $a=2, b=-7, c=3$ and $d=-8$. So the characteristic equation is $\lambda^2 - (a+d)\lambda + (ad - bc) = 0$. When we put the values of a, b, c, d here okay so what do we get $\lambda^2 - (a+d)\lambda + (ad - bc) = 0$, so $2-8$ means -6 so we get $\lambda^2 + 6\lambda$ and then $ad - bc$, ad is -16 and then we have bc , $bc = -21$ so $-16 - (-21) = 5$. So we get $\lambda^2 + 6\lambda + 5 = 0$. The factors here are $\lambda + 5$ and $\lambda + 1$.

So the eigen values are $\lambda = -5$ and $\lambda = -1$. Thus we can see that the roots of the equation are the roots of the characteristic equation are real unequal and they are of the same sign. And therefore why the case 1 which we have considered in the previous lecture. The critical point $(0,0)$ here is a node and it is asymptotically stable.

(Refer Slide Time: 02:07)

Case II:

Theorem: The roots λ_1 and λ_2 of the characteristic equation

$$\lambda^2 - (a + d)\lambda + (ad - bc) = 0 \quad (*)$$

are real, unequal and of opposite sign. Then the critical point (0,0) of linear system

$$\frac{dx}{dt} = ax + by,$$

$$\frac{dy}{dt} = cx + dy,$$

(1)

Is a saddle point.

Now let us go to the case 2 here we will consider the case where lambda 1 and lambda 2 are real, equal and are of opposite signs, so let us say the root lambda 1 and lambda 2 of the characteristic equation lambda square-a+d lambda+ad-bc=0 are real unequal and of opposite signs. So, then the critical point 00 of the linear system we shall see is a saddle point.

(Refer Slide Time: 02:32)

Proof: Suppose $\lambda_1 < 0 < \lambda_2$. The general solution of the system is given by

$$x = c_1 A_1 e^{\lambda_1 t} + c_2 A_2 e^{\lambda_2 t},$$

$$y = c_1 B_1 e^{\lambda_1 t} + c_2 B_2 e^{\lambda_2 t},$$

(;

where A_1, B_1, A_2 and B_2 are definite constants and $A_1 B_2 \neq A_2 B_1$, and where c_1 and c_2 are arbitrary constants.

Choosing $c_2 = 0$, we obtain the solutions

$$x = c_1 A_1 e^{\lambda_1 t},$$

$$y = c_1 B_1 e^{\lambda_1 t}.$$

$$\begin{matrix} c_1 > 0 & x = A_1 e^{\lambda_1 t} \\ c_1 < 0 & y = \frac{B_1}{A_1} x \end{matrix}$$

(;

Now let us see how do we get a saddle point here, suppose lambda 1 is <0 and lambda 2 is >0, so that means lambda 1 is negative and lambda 2 is positive. This we do for definiteness. The general solution of the system 1 here is then given by $x=c_1 A_1 e$ to the power lambda 1 t + $c_2 A_2 e$ to the power lambda 2 t and $y=c_1 B_1 e$ to the power lambda 1 t + $c_2 B_2 e$ to the power lambda 2 t. And $A_1 B_1 A_2$ and B_2 are definite constants.

And $y=c_1 B_1 e^{\lambda_1 t} + c_2 B_2 e^{\lambda_2 t}$ and $A_1 B_1 A_2$ and B_2 are definite constants and satisfy the condition that $A_1 B_2 \neq A_2 B_1$ and c_1 and c_2 are arbitrary constants. Now we will analyze the situation here that was analyzed in case 1 okay so choosing $c_2=0$ what do we obtain, we obtain $x=c_1 A_1 e^{\lambda_1 t}$ and $y=c_1 B_1 e^{\lambda_1 t}$.

Now let us assume that $c_1 > 0$ then what will happen when we assume $c_1 > 0$ then these two equations $B_1 x = A_1 y$. So, in this solution $c_1 > 0$ in this case $B_1 x = A_1 y$ this gives you half line path okay and since λ_1 is negative and t goes to infinity okay x goes to 0 and y goes to 0. So, that means the half line path $B_1 x = A_1 y$ enters 00 as t goes to infinity, and when we take $c_1 < 0$ we get the other half line path given by the line $B_1 x = A_1 y$.

So, this solution $x=c_1 A_1 e^{\lambda_1 t}$ $y=c_1 B_1 e^{\lambda_1 t}$ represents two half line paths okay which approach an enter 00 as t goes to $+\infty$, because λ_1 is negative and the line is given by $B_1 x = A_1 y$. SO they enter 00 with the slope $y = B_1/A_1 x$ the slope of the line is B_1/A_1 .

(Refer Slide Time: 05:10)

If we choose $c_1 = 0$, we obtain the solutions

$$x = c_2 A_2 e^{\lambda_2 t},$$

$$y = c_2 B_2 e^{\lambda_2 t}.$$

(4)

*if $c_2 > 0$
 $B_2 x = A_2 y$
 $c_2 < 0$
 $x \rightarrow 0, y \rightarrow -\infty$*

There are two half line paths, which approach and enter $(0,0)$ as $t \rightarrow +\infty$ and two other half-line paths which approach and enter $(0,0)$ as $t \rightarrow -\infty$.

All other paths are non-rectilinear paths which do not approach $(0,0)$ as $t \rightarrow +\infty$ or as $t \rightarrow -\infty$ but which become asymptotic to one or another of the four half-line paths as $t \rightarrow +\infty$ and as $t \rightarrow -\infty$. Thus, the critical point $(0,0)$ is a saddle point and it is unstable as shown in the fig.1. *$c_1 \neq 0, c_2 \neq 0$*

Now when we take $c_1=0$ $x=c_2 A_2 e^{\lambda_2 t}$ and $y=c_2 B_2 e^{\lambda_2 t}$, this also gives two half line paths which are given by $B_2 x = A_2 y$, if you take $c_2=0$ then the

half line path is given by $B_2x=A_2y$ when $c_2 < 0$ then we get the other half line path given by the equation $B_2x=A_2y$. But since $\lambda_2 > 0$ here as t goes to $-\infty$ x and y goes to 0 x goes to 0 y goes to 0 and t goes to $-\infty$.

So these two half line paths enter 00 when t goes to $-\infty$. Now let us take $c_1 \neq 0$ $c_2 \neq 0$ when $c_1 \neq 0$, $c_2 \neq 0$ then what do we get.

(Refer Slide Time: 06:22)

Proof: Suppose $\lambda_1 < 0 < \lambda_2$. The general solution of the system is given by

$$\begin{aligned} x &= c_1 A_1 e^{\lambda_1 t} + c_2 A_2 e^{\lambda_2 t}, \\ y &= c_1 B_1 e^{\lambda_1 t} + c_2 B_2 e^{\lambda_2 t}, \end{aligned} \tag{2}$$

where A_1, B_1, A_2 and B_2 are definite constants and $A_1 B_2 \neq A_2 B_1$, and where c_1 and c_2 are arbitrary constants.

Choosing $c_2 = 0$, we obtain the solutions

$$\begin{aligned} x &= c_1 A_1 e^{\lambda_1 t}, \\ y &= c_1 B_1 e^{\lambda_1 t}. \end{aligned} \tag{3}$$

Handwritten notes:
 $c_1 > 0 \Rightarrow x = A_1 t, y = \frac{B_1}{A_1} t$
 $c_1 < 0 \Rightarrow y = \frac{B_1}{A_1} t$
 $\frac{y}{x} = \frac{c_1 B_1 e^{\lambda_1 t} + c_2 B_2 e^{\lambda_2 t}}{c_1 A_1 e^{\lambda_1 t} + c_2 A_2 e^{\lambda_2 t}} = \frac{\left(\frac{B_1}{A_1}\right) e^{(\lambda_1 - \lambda_2)t} + \frac{B_2}{A_2}}{\left(\frac{A_1}{c_2}\right) e^{(\lambda_1 - \lambda_2)t} + A_2}$
 $\lim_{t \rightarrow \infty} \frac{y}{x} = \frac{B_2}{A_2}$

We have $x = c_1 A_1$ when $c_1 \neq 0$ and then $c_1 \neq 0$ then these two parts this solution 2 represents rectilinear paths because as t goes to $-\infty$ this part e to the power $\lambda_1 t$ goes to 0 but e to the power $\lambda_2 t$ goes to infinity. As λ_2 is positive. Similarly, for the case solution y e to the power $\lambda_1 t$ goes to 0 as t goes to infinity while e to the power $\lambda_2 t$ goes to infinity as t goes to infinity so one part goes to 0 while the other part goes to infinity.

And same is the situation when t goes to $-\infty$, when t goes to $-\infty$ e to the power $\lambda_1 t$ goes to infinity while e to the power $\lambda_2 t$ goes to 0 . So, the solution 2 represent rectilinear paths and do not approach to 00 or as t goes to $+\infty$ or $-\infty$. Let us look at y/x so y/x in this case is $c_1 B_1 e^{\lambda_1 t} + c_2 B_2 e^{\lambda_2 t} / c_1 A_1 e^{\lambda_1 t} + c_2 A_2 e^{\lambda_2 t}$.

Let us divide this numerator and denominator value to the power $\lambda_2 t$ so that we get C_1

B1 first let us divide /c2 and then we will divide by e to the power lambda 2t. So, what do we get, c1 B1 e to the power lambda 1-lambda 2 t+B2 and we divide by here we take also c1 A1/c2 and then e to the power lambda 1-lambda 2*t+A2. So, as 2 goes to infinity since lambda 1 < lambda 2 lambda1-lambda2 is negative.

So as t goes to infinity e to the power lambda1-lambda2 goes to 0 and therefore y/x=B2/A2 and therefore what we can say is that the rectilinear paths enter 00 with slope B2/A2.

(Refer Slide Time: 09:02)

If we choose $c_1 = 0$, we obtain the solutions

$$x = c_2 A_2 e^{\lambda_2 t},$$

$$y = c_2 B_2 e^{\lambda_2 t}.$$

(4)

*if $c_2 > 0$
 $B_2 x = A_2 y$
 $c_2 < 0$
 $x > 0, y < 0$
 $x < 0, y > 0$*

There are two half line paths, which approach and enter (0,0) as $t \rightarrow +\infty$ and two other half-line paths which approach and enter (0,0) as $t \rightarrow -\infty$. All other paths are non-rectilinear paths which do not approach (0,0) as $t \rightarrow +\infty$ or as $t \rightarrow -\infty$ but which become asymptotic to one or another of the four half-line paths as $t \rightarrow +\infty$ and as $t \rightarrow -\infty$. Thus, the critical point (0,0) is a saddle point and it is unstable as shown in the fig.1. *$c_1 \neq 0, c_2 \neq 0$*

So, we have there are two half line paths we can conclude that there are two half line paths which approach and enter 00 as t goes to infinity and two other half line paths which approach and enter 00 as t goes to -infinity. This is in the case where we have taken $c_2=0$ and this is +infinity. Two other half line path which enter 00 as t goes to -infinity. This is the case where we have taken $c_2=0$ and this is the case where we can take $c_1=0$.

All other paths are non-rectilinear paths that means when we have taken $c_1 \neq 0$ and $c_2 \neq 0$ which do not approach 00 as t goes to +infinity or t goes to -infinity. But which become asymptotic to one or another of the four half line paths. So, this means that these are non-rectilinear paths which do not approach to 00 as goes to infinity. This is what we have y/x y/x is the slope of any point xy on the rectilinear paths this is B2/A2.

Okay, so this means that the slope of the tangent to the rectilinear path approaches to B^2/A^2 that means the slope of the line $B^2x=A^2y$ $B^2x=A^2y$ this line has the slope B^2/A^2 . So, the non-rectilinear paths approach or become asymptotic to the rectilinear path $B^2x=A^2y$. So, they do not approach 00 as t goes to $+\infty$ or t goes to $-\infty$ but which asymptotic to one or another of the four half line paths as t goes to $+\infty$ or t goes to $-\infty$.

Thus the critical point 00 is a saddle point and it is unstable as shown in the figure.

(Refer Slide Time: 10:50)

Fig 1

As shown in this figure this is your half line path as t goes to $+\infty$ and it goes to 00 so it enters 00 as t goes to $+\infty$. Now this is another half line paths those one as t goes to $-\infty$ okay it enters 00 and the directions are opposite. The directions are towards point 00 now here they are above from the origin and above from 00 . Now these paths are non-rectilinear paths and you can see that they become asymptotic to one of the two half line oaths this one.

These are asymptotic to half line paths and these are asymptotic too this half line path. So, they become asymptotic to one of the half line paths therefore this point at origin is a saddle point and these non-rectilinear paths do not approach 00 as t goes to $+\infty$ or $-\infty$.

(Refer Slide Time: 12:01)

Example: Let us consider

$$\frac{dx}{dt} = x, \quad \frac{dy}{dt} = -y.$$

*a=1, b=0
c=0, d=-1
 $\lambda^2 - (a+d)\lambda + (ad-bc) = 0$
 $\lambda^2 - 1 = 0$
 $\lambda = \pm 1$*

Then Eigen values are $\lambda = 1, -1$.

The roots are **real unequal and of opposite sign**.

\Rightarrow the critical point $(0,0)$ is a **saddle point** and it is **unstable**.

Now let us consider the example of $dx/dt=x$ $dy/dt=-y$ so $a=1$ $b=0$ $c=0$ and $d=-1$ so what do we have $\lambda^2 - a + d$ $a+d$ means $1-0$ so $0 * \lambda$ and then $+ad$ ad is $-1-bc$ okay. So, $\lambda^2 - 1 = 0$ and therefore $\lambda = \pm 1$ so Eigen values are $\lambda = 1, -1$ they are real unequal and of opposite sign. So, we have case two here and just now we have seen eigen values are real, unequal and of opposite sign. Then the critical point 00 is a saddle point and it is unstable.

(Refer Slide Time: 13:01)

This is the figure here we can see here the two half line paths are this is an half line path this is another half line path. This is other side of the half line path and this is one half line path this one and this is another half line path and these are non-rectilinear paths which become asymptotic to the two half line paths this one and this one goes to $+\infty$ or $-\infty$. Now here 00 is a saddle

point and it is unstable.

(Refer Slide Time: 13:29)

Case III:

Theorem: Let the roots λ_1 and λ_2 of the characteristic equation be real and equal. Then the critical point (0,0) of the linear system (1) is a node.

Proof: Let $\lambda_1 = \lambda_2 = \lambda < 0$. First, let us consider the case when $a = d \neq 0$, $b = c = 0$. Then the characteristic equation becomes

$$\lambda^2 - 2a\lambda + a^2 = 0$$

and hence $\lambda = a = a$. The system (1) becomes

$$\frac{dx}{dt} = \lambda x, \quad \frac{dy}{dt} = \lambda y$$

$$\Rightarrow x = c_1 e^{\lambda t}, y = c_2 e^{\lambda t}$$

Handwritten notes:

- $x_1 = c_1 e^{\lambda t}$
- $x_2 = c_2 e^{\lambda t}$
- $f = (a+d)\lambda + (ad-bc) \Rightarrow$
- $a = d \neq 0$
- $b = c = 0$
- $\lambda^2 - 2a\lambda + a^2 = 0$
- $(\lambda - a)^2 = 0$
- $\lambda = a = a$
- $\frac{dx}{dt} = ax + by$
- $\frac{dy}{dt} = cx + dy$
- (5)

Now let us consider the case 3 where we will assume lambda 1 and lambda 2 of the system are real and equal. So, let us say the roots of lambda 1 and lambda 2 of the characteristic equation be real and equal then we are going to show that the critical point 00 of the linear system is a node. So, let us begin with the situation where lambda 1 and lambda 2 are both equal to lambda and lambda is negative.

So, we are assuming that both roots of the characteristic equation are equal, real, equal and are negative. So, first let us consider the case when a=d now let us look at the characteristic equation characteristic equation is lambda square-a+d*lambda+ad-bc=0 okay for the equal roots we must have B2=4ac of the quadratic equation. So, that we can achieve in this case that is one case is a= d !=0 suppose if I write a=d is !=0 and bc=0.

Then what I will get I will get lambda square-2 a lambda+a square=0 moreover we will have ad-bc which is=a square a is non-0 so ad-bc is non-0. Now these two roots of this equation are a each okay. So, the characteristic equation lambda square-a+d lambda+ad-bc=0 becomes lambda square-2a lambda+a square=0 and therefore lambda=a a=d. SO, the system of the co efficient are dx/dt=ax+by dy/dt=cx+dy.

So $a=\lambda$ and $b=0$ and I will get $\frac{dx}{dt}=\lambda x$ and here $c=0$ $d=\lambda$ so we have $\frac{dy}{dt}=\lambda y$ and we know how to find system the general solution of an equation of the type $\frac{dx}{dt}=\lambda x$, so the solution is you can write $\frac{dx}{x}=\lambda dt$ and you can integrate you will get $x=\text{some constant } c_1 e^{\lambda t}$, and similarly $\frac{dy}{dt}=\lambda y$ will give you other solution $y=c_2 e^{\lambda t}$.

(Refer Slide Time: 16:20)

Since $c_1 y = c_2 x$, the paths defined by (5) for the various values of c_1 and c_2 are half-line paths of all possible slopes. Further, since $\lambda < 0$, each of these half-lines approaches and enters $(0,0)$ as $t \rightarrow +\infty$. Hence the critical point is a node and it is asymptotically stable.

If $\lambda > 0$, we have the same situation except that the paths enter $(0,0)$ as $t \rightarrow -\infty$, the node $(0,0)$ is unstable and the arrows in fig.2 are all reversed.

This type of node is called *a star-shaped node*.

Now you can see from here we have $x=c_1 e^{\lambda t}$ and $y=c_2 e^{\lambda t}$ so what will you get you will get this equation $c_1 y=c_2 x$ okay $c_1 y=c_1 c_2 e^{\lambda t}$ which is $=c_2 x$ okay we will get this equation $c_1 y=c_2 x$ now the paths defined by 5 defined by this 5 $x=c_1 e^{\lambda t}$ $y=c_2 e^{\lambda t}$ for the various values of c_1 c_2 are half line paths of all possible slopes.

And slopes will be you can see slope will be you can take any point xy on the path then the slope of the line joining the point xy to the origin will be y/x which is $=c_2/c_1$ and so when c_1 and c_2 are arbitrary you can say that you will get half line paths of all possible slopes. Further since $\lambda < 0$ see here $\lambda < 0$ so as t goes to infinity of these half line paths approaches and enters 00 as t goes to $+\infty$.

And therefore we can say that the critical point is a node and also it is asymptotically stable. If λ is positive, we will have the same situation we will have the same equation $c_1 y=c_2 x$. So

we will have for various values of c_1 and c_2 we will have half line paths but because λ is positive these half line paths will enter 00 as t goes to-infinity and therefore point 00 is unstable.

The node at 00 is unstable and the arrows will be having opposite directions will all be reversed. Such type of node we will call as star shaped node.

(Refer Slide Time: 18:34)

Fig. 2 ◦

So you can see the situation here this is the case where we are taking λ to be negative. So all the it is a star shaped node here the directions are towards the center if you take λ to be positive these directions of arrows will be opposite to the directions here. So it is a star shaped figure so we call it as star shaped node.

(Refer Slide Time: 19:02)

Now, let us consider all other possibilities which lead to a double root.

Then the general solution of system (1) is given by

$$\begin{aligned} x &= c_1 A e^{\lambda t} + c_2 (A_1 t + A_2) e^{\lambda t}, \\ y &= c_1 B e^{\lambda t} + c_2 (B_1 t + B_2) e^{\lambda t}, \end{aligned} \quad (2)$$

where the A's and B's are definite constants and such that $\frac{B_1}{A_1} = \frac{B}{A}$ and

c_1 and c_2 are arbitrary constants. If we choose $c_2 = 0$,

$$\begin{aligned} x &= c_1 A e^{\lambda t}, \\ y &= c_1 B e^{\lambda t}. \end{aligned} \quad (3)$$

Then there are two half-line paths which approach and enter (0,0) as $t \rightarrow +\infty$ with slope B/A.

Now let us consider the other possibilities which will lead us to a double root that means where the quadratic equation the characteristic equation $\lambda^2 - a\lambda + ad - bc = 0$ gives us double root in those possibilities let us consider now. So, in those possibilities the general solution of the system we can write as $x = c_1 A e^{\lambda t} + c_2 (A_1 t + A_2) e^{\lambda t}$ and $y = c_1 B e^{\lambda t} + c_2 (B_1 t + B_2) e^{\lambda t}$.

Now A 's and B 's here are definite constants and they are such that $B_1/A_1 = B/A$. c_1 and c_2 are arbitrary constants. Now if you take $c_2 = 0$ here what do you get from here $x = c_1 A e^{\lambda t}$ and $y = c_1 B e^{\lambda t}$ okay now then there are two half line paths which approach and enter 00 as t goes to infinity.

We are taking λ to be negative, we have taken that $\lambda_1 = \lambda_2 = \lambda$ which is negative, so x and y both approach to 0 as t goes to $+\infty$ if you take $c_1 = 0$ we will get one half line path if you take $c_1 < 0$ we will get the other half line path both the half line path will approach and enter 00 as t goes to $+\infty$ and when you consider the other case. So there are two half line paths which approach and enter 00 as t goes to infinity.

And the slope is y/x means B/A.

(Refer Slide Time: 20:50)

If $c_2 \neq 0$, the general solution (2) represents non-rectilinear paths. Since $\lambda < 0$ we have $\lim_{t \rightarrow +\infty} x = 0$, $\lim_{t \rightarrow +\infty} y = 0$.

Thus, all the non-rectilinear paths approach $(0,0)$ as $t \rightarrow +\infty$. Further,

$$\frac{y}{x} = \frac{\frac{c_1 B}{c_2} + (B_2 + B_1 t)}{\frac{c_1 A}{c_2} + (A_2 + A_1 t)} \Rightarrow \lim_{t \rightarrow +\infty} \frac{y}{x} = \frac{B_1}{A_1} = \frac{B}{A}.$$

Hence, all the rectilinear paths enter $(0,0)$ with limiting slope B/A .

Thus all the paths (both rectilinear and non-rectilinear) enter $(0,0)$ as $t \rightarrow +\infty$ with slope B/A . Hence, the critical point $(0,0)$ is a node and it is asymptotically stable as shown in fig.3.

So, with the slope B/A if $c_2 \neq 0$ now let us consider this equation $c_2 \neq 0$ then the general solution 2 represents non-rectilinear paths if $c_2 \neq 0$ then the general solution is non-rectilinear paths and what we have since λ is negative all these non-rectilinear paths satisfy the equation limited as x t towards infinity is 0 and limit of y t tends to infinity.

So, all these non-rectilinear paths enter 00 as t goes to infinity further if you find y/x . Since c_2 is non-0 we can divide the numerator and denominator by c_2 and we get $c_1 B/c_2 + B_2 + B_1 t = c_1 A/c_2 + A_2 + A_1 T$ and when t goes to infinity we can see here we can divide the numerator and denominator further by t so that $c_1 B/c_2 t + B_2/t + B_1$ and here we will have $c_1 A/c_2 t$.

I mean to say this when you divide when you want to take the limit as t goes to infinity you write y/x as $c_1 B/C_2 t + B_2 y t + B_1$ and similarly in the denominator we write $c_1 A/c_2 t + A_2/t + A_1$ so as t goes to infinity we will have the limit as B_1/A_1 which is $=B/A$. Hence all the rectilinear paths enter 00 with slope B/A . Thus all the paths both rectilinear and non-rectilinear enter 00 as t goes to infinity with slope B/A .

In the case of rectilinear paths also we have seen that the slope is B/A . Hence the critical point B/A is unknown and it is asymptotically stable as shown in figure 3.

(Refer Slide Time: 23:02)

Fig. 3

As you can see these are non-rectilinear paths okay they are entering 00 with the slope of the line $Bx=Ay$ slope of the line $Bx=Ay$ is B/A okay this gives you $y = B/A * x$ and you can see $y = B/A$ becomes the tangent to the non-rectilinear paths while passing through the origin. So, these non-rectilinear paths approach and enter 00 with slope B/A and the slope of the half line path has B/A . So, this point 00 is a node and it is asymptotically stable.

(Refer Slide Time: 23:46)

Example: Let us consider

$$\frac{dx}{dt} = -x, \quad \frac{dy}{dt} = -y.$$

Then Eigen values are $\lambda = -1, -1$.

The roots are **real and equal**.

\Rightarrow the critical point $(0,0)$ is a **node** and it is **asymptotically stable**.

$$A = \begin{bmatrix} a & b \\ c & d \end{bmatrix} = \begin{bmatrix} -1 & 0 \\ 0 & -1 \end{bmatrix}$$

$$|A - \lambda I| = \begin{vmatrix} -1 - \lambda & 0 \\ 0 & -1 - \lambda \end{vmatrix} = 0$$

$$\Rightarrow \lambda = -1, -1$$

Now let us take an example on this. Suppose we consider $dx/dt = -x$ $dy/dt = -y$ then the matrix here is $A = abcd$ so this is $-1 \ 0 \ 0 \ -1$ okay the equivalent of $A - \lambda I = 0$ will give you $-1 - \lambda \ 0 \ 0 \ -1 - \lambda$ so $\lambda = -1, -1$ okay so the eigen values are real and equal they have negative sign, the critical point 00 we have discussed right now the critical point 00 is a node and it is

asymptotically stable.

(Refer Slide Time: 24:37)

And this is the figure you can see you get the point 00 is a node and it is asymptotically stable this is the case of a star shaped node here we have a star shaped node like in the case this one, since we have star shaped node we have this assumption $a=d$ d is $\neq 0$ $b=c=0$. This is a special situation where we get a star shaped node root in this case are equal okay root in the other cases we discussed are also equal.

In this case we get a star shaped node and there we get a node which is not star shaped. SO, here you can see the example which we have taken here $a=d$ $a= -1$ okay and $b=c=0$ till we get a star shaped node okay. So, this node is a star shaped node and this is asymptotically stable the figure is this one.

(Refer Slide Time: 25:52)

Example: Let us consider

$$\frac{dx}{dt} = x, \quad \frac{dy}{dt} = y.$$

Then Eigen values are $\lambda = 1, 1$.

The roots are **real and equal**.

\Rightarrow the critical point $(0,0)$ is a **node** and it is **unstable**.

0

Now let us consider another example $dx/dt=x$ and $dy/dt=y$ so here again we will get $A=1 \ 0 \ 0 \ 1$ so this is unique matrix the eigen values are 1 1 okay so the eigen values are 1.1 they are real eigen values are equal okay. In this case you can see again $a=d \neq 0$ $a=d=1 \neq 0$ and b and c are 0 okay so we get the critical point is a node but remember here λ is positive λ is not negative λ is positive the roots are real and equal. So, it is a node but it is unstable.

(Refer Slide Time: 26:44)

<i>Nature of roots λ_1 and λ_2 of characteristic equation (*)</i>	<i>Nature of critical point $(0,0)$ of linear system (1)</i>	<i>Stability of critical point $(0,0)$</i>
Real, unequal, and of same sign	Node	Asymptotically stable if roots are negative; unstable if roots are positive
Real, unequal, and of opposite sign	Saddle point	Unstable
Real and equal	Node	Asymptotically stable if roots are negative; unstable if roots are positive

Now we have compiled the summations that we have so far regarding the Eigen values λ_1 λ_2 the nature of the critical point depending of the Eigen values and the stability of the critical point which can be unsolved from the nature of the root λ_1 and λ_2 . So, let us summaries what we have done so far so if the eigen values λ_1 and λ_2 of the

characteristic equation of the matrix A are real unequal and of the same sign.

Then the nature of the critical point of linear system is a node and it is asymptotically stable if roots are negative, unstable if roots are positive> now here if the eigen values of λ_1 and λ_2 are real and unequal and opposite sign then we have a saddle point and stability of the critical point is unstable. Here we have λ_1 and λ_2 are real and equal you will have a node in the case where λ is positive.

Okay we will have a star shaped node while in the case where λ is positive we will have unstable node so it is asymptotically stable if the roots are stable star shaped node if asymptotically stable if roots are negative again if the roots are positive they will again have a node but it will be unstable. So, with this I will conclude my lecture thank you very much for your attention.
