Lecture - 24
Stability of Linear Systems- III

Hello friends welcome to my next lecture on stability of linear systems. Let us consider the linear system as we said.

(Refer Slide Time: 00:35)

Let us consider linear system

$$\begin{aligned}\frac{dx}{dt} &= ax + by, \\ \frac{dy}{dt} &= cx + dy.\end{aligned}\tag{1}$$

$\frac{dx}{dt}=ax+by$ $\frac{dy}{dt}=cx+dy$

(Refer Slide Time: 00:39)

Case IV:

Theorem: The roots λ_1 and λ_2 of the characteristic equation

$$\lambda^2 - (a + d)\lambda + (ad - bc) = 0 \quad (*)$$

are conjugate complex with real part not zero (i.e. not purely imaginary).

Then the critical point (0,0) of the linear system (1) is a spiral point.

Proof: Let $\lambda_1 = \alpha + i\beta$ and $\lambda_2 = \alpha - i\beta$, where $\alpha, \beta \in \mathfrak{R} - \{0\}$. Then, the general solution of the system (1) is given by

$$\begin{aligned} x &= e^{\alpha t} [c_1 (A_1 \cos \beta t - A_2 \sin \beta t) + c_2 (A_2 \cos \beta t + A_1 \sin \beta t)], \\ y &= e^{\alpha t} [c_1 (B_1 \cos \beta t - B_2 \sin \beta t) + c_2 (B_2 \cos \beta t + B_1 \sin \beta t)], \end{aligned} \quad (2)$$

where A_1, A_2, B_1 and B_2 are definite constants and c_1 and c_2 are arbitrary constants.

Now we are going to discuss the fourth here the roots λ_1 and λ_2 of the characteristic equation are conjugate complex with real parts $\neq 0$ that means the roots are not purely imaginary. So let us consider this case here we shall see that the critical point (0,0) of the linear system is a spiral point. So, let us see how we get this situation suppose $\lambda_1 = \alpha + i\beta$ and $\lambda_2 = \alpha - i\beta$.

Where α and β are both non-zero real numbers that is $\alpha, \beta \in \mathfrak{R} - \{0\}$ and then the general solution of the linear system (1) is given by $x = e^{\alpha t} [c_1 (A_1 \cos \beta t - A_2 \sin \beta t) + c_2 (A_2 \cos \beta t + A_1 \sin \beta t)]$ and $y = e^{\alpha t} [c_1 (B_1 \cos \beta t - B_2 \sin \beta t) + c_2 (B_2 \cos \beta t + B_1 \sin \beta t)]$ and A_1, A_2, B_1 and B_2 are definite constants and c_1 and c_2 are arbitrary constants.

(Refer Slide Time: 01:52)

Let $\alpha < 0$. Then from (4) we have $\lim_{t \rightarrow +\infty} x = 0$, $\lim_{t \rightarrow +\infty} y = 0$. Hence, all paths defined by (2) approach (0,0) as $t \rightarrow +\infty$. Now, (2) can be expressed as

$$\begin{aligned} x &= e^{\alpha t} [c_3 \cos \beta t + c_4 \sin \beta t], \\ y &= e^{\alpha t} [c_5 \cos \beta t + c_6 \sin \beta t], \end{aligned} \quad (3)$$

where $c_3 = c_1 A_1 + c_2 A_2$, $c_4 = c_2 A_1 - c_1 A_2$, $c_5 = c_1 B_1 + c_2 B_2$, and $c_6 = c_2 B_1 - c_1 B_2$.

Let c_1, c_2 be real. Then, we may write the solution (3) as

$$\begin{aligned} x &= K_1 e^{\alpha t} \cos(\beta t + \phi_1), \\ y &= K_2 e^{\alpha t} \cos(\beta t + \phi_2), \end{aligned}$$

o

First, we consider the case when the real parts of the roots λ_1 and λ_2 are negative then we can see from the equation then we see from here that when α is negative x and y both go to 0 as t goes to $+\infty$. So, then from (2) we see that the limit of x as t goes to $+\infty$ is 0 and the limit of y as t goes to $+\infty$ is 0 and therefore all paths defined by (2) approach (0,0) as t goes to $+\infty$.

Now we can write the equations (2) by collecting the coefficients of $\cos \beta t$ and $\sin \beta t$ in x and y and they can be expressed in this form $x = e^{\alpha t} [c_3 \cos \beta t + c_4 \sin \beta t]$ and $y = e^{\alpha t} [c_5 \cos \beta t + c_6 \sin \beta t]$ and when you do this that is you collect the coefficients of $\cos \beta t$ and $\sin \beta t$ it turns out that the values of c_3, c_4, c_5 and c_6 .

Are given by $c_3 = c_1 A_1 + c_2 A_2$, $c_4 = c_2 A_1 - c_1 A_2$, $c_5 = c_1 B_1 + c_2 B_2$ and $c_6 = c_2 B_1 - c_1 B_2$. Now let us assume that c_1 and c_2 be real numbers then this representation of x and y can be further written in this form $x = K_1 e^{\alpha t} \cos(\beta t + \phi_1)$ and $y = K_2 e^{\alpha t} \cos(\beta t + \phi_2)$.

(Refer Slide Time: 03:47)

where $K_1 = \sqrt{c_3^2 + c_4^2}$, $K_2 = \sqrt{c_5^2 + c_6^2}$ and ϕ_1 and ϕ_2 are defined by

$$\cos \phi_1 = \frac{c_3}{K_1}, \cos \phi_2 = \frac{c_5}{K_2},$$

$$\sin \phi_1 = -\frac{c_4}{K_1} \text{ and } \sin \phi_2 = -\frac{c_6}{K_2}.$$

And while doing this it is easy to see that K_1 is under root c_3 square + c_4 square and k_2 is under root c_5 square + c_6 square and ϕ_1 and ϕ_2 are defined by the equations $\cos \phi_1 = c_3/K_1$ $\cos \phi_2 = c_5/K_2$ $\sin \phi_1 = -c_4/K_1$ and $\sin \phi_2 = -c_6/K_2$

(Refer Slide Time: 04:09)

Now, let us consider

$$\frac{y}{x} = \frac{K_2 e^{at} \cos(\beta t + \phi_2)}{K_1 e^{at} \cos(\beta t + \phi_1)}$$

Suppose $K = K_2/K_1$ and $\phi_3 = \phi_1 - \phi_2$ then

$$\begin{aligned} \frac{y}{x} &= \frac{K \cos(\beta t + \phi_1 - \phi_3)}{\cos(\beta t + \phi_1)} \\ &= K \left\{ \frac{\cos(\beta t + \phi_1) \cos \phi_3 + \sin(\beta t + \phi_1) \sin \phi_3}{\cos(\beta t + \phi_1)} \right\} \\ &= K \{ \cos \phi_3 + \tan(\beta t + \phi_1) \sin \phi_3 \}, \end{aligned} \quad (4)$$

Provided $\cos(\beta t + \phi_1) \neq 0$.

Now let us consider the ratio of y and x so let us consider y/x y is K_2 times e to the power αt $\cos(\beta t + \phi_2)$ and x is K_1 times e to the power $\alpha t \cos(\beta t + \phi_1)$ so when we divide y/x e to the power αt will get cancelled and so k will let us if you note $K_2/K_1 = K$ then y/x will be $K \cos(\beta t + \phi_1 - \phi_3)$ let us take difference of ϕ_1 and ϕ_2 to be ϕ_3 .

So, then $\phi_2 = \phi_1 - \phi_3$ you will have $K \cos(\beta t + \phi_1 - \phi_3)$ over $\cos(\beta t + \phi_1)$. Let us

expand $\cos(\beta t + \phi_1 - \phi_3)$ we will have $\cos(\beta t + \phi_1) \cos \phi_3$ and $+\sin(\beta t + \phi_1) \sin \phi_3$ and $-\cos(\beta t + \phi_1) \sin \phi_3$ and $+\sin(\beta t + \phi_1) \cos \phi_3$. So, when we divide by $\cos(\beta t + \phi_1)$ assuming that $\cos(\beta t + \phi_1) \neq 0$ what do we get y/x we will get as $k \tan(\beta t + \phi_1) \sin \phi_3$.

(Refer Slide Time: 05:19)

Since the trigonometric functions occurring in (4) are periodic, it follows

that $\lim_{t \rightarrow \infty} \frac{y}{x}$ does not exist and hence the paths do not enter $(0,0)$. Instead,

the paths approach $(0,0)$ in a spiral-like manner, winding around $(0,0)$ an infinite number of times as $t \rightarrow +\infty$.

Hence, the critical point $(0,0)$ is a spiral-point and it is asymptotically stable as shown in fig.1.

If $\alpha > 0$, the solution is the same except that the path approach $(0,0)$ as $t \rightarrow -\infty$, the spiral point $(0,0)$ is unstable and the arrows in fig.1 are reversed.

Now the trigonometric functions occurring in 4 you can see here the functions are trigonometric functions they are periodic $\cos \phi_3$ is periodic, $\sin \phi_3$ is periodic $\cos(\beta t + \phi_1)$ is also periodic. So, since the trigonometric functions occurring in 4 are periodic followed that limit $t \rightarrow \infty$ y/x does not exist okay so here as t tends to infinity does not exist.

And so what we get hence the paths do not enter $0,0$ instead the paths approach $0,0$ in a spiral manner winding around $0,0$ an infinite number of times as t goes to $+\infty$ and hence the critical point $0,0$ is a spiral point and it is asymptotically stable as shown in the figure 1

(Refer Slide Time: 06:09)

Fig.1

You can see here they are binding around 0,0 in a spiral like manner and approaching 0,0 in a spiral like manner by binding around 0,0 infinite number of times. Now 0,0 is a spiral point and it is asymptotically stable if $\alpha > 0$ if the real parts of the roots of λ are < 0 and $\beta \neq 0$ which is $\alpha > 0$ then the solution we get the same solution that means we again have 0,0 a spiral point.

That is the path approach 0,0 as t goes to $-\infty$ and the spiral point 0,0 is unstable because the arrows now are reversed. So, when $\alpha > 0$ again we get the same situation but the arrows will now be in the opposite direction so we have this.

(Refer Slide Time: 07:03)

Example: Let us consider the linear system

$$\frac{dx}{dt} = 2x + 4y, \quad \frac{dy}{dt} = -2x + 6y.$$

Then Eigen values are $\lambda = 4 \pm 2i$.

The roots are **conjugate complex but not purely imaginary.**

\Rightarrow the critical point (0,0) is a **spiral point** and it is **unstable**.

$\alpha = 4, \beta = 2$
 $\alpha, \beta \in \mathbb{R} - \{0\}$
 Since $\alpha > 0$
 (positive) spiral point

$$A = \begin{bmatrix} 2 & 4 \\ -2 & 6 \end{bmatrix}$$

$$|A - \lambda I| = \begin{vmatrix} 2-\lambda & 4 \\ -2 & 6-\lambda \end{vmatrix} = 0$$

$$\Rightarrow (2-\lambda)(6-\lambda) + 8 = 0$$

$$(2-\lambda)(6-\lambda) + 8 = 0$$

$$\lambda^2 - 8\lambda + 20 = 0$$

$$\lambda = \frac{8 \pm \sqrt{64 - 80}}{2}$$

$$= \frac{8 \pm \sqrt{64 - 80}}{2}$$

$$= \frac{8 \pm 4i}{2} = 4 \pm 2i$$

And now consider the linear system an example over this $dx/dy=2x+4y$ $dy/dt=-2x+6y$ so here $A=\begin{pmatrix} 2 & 4 \\ -2 & 6 \end{pmatrix}$ and so the characteristic equation Determinant $A - \lambda I = \begin{vmatrix} 2-\lambda & 4 \\ -2 & 6-\lambda \end{vmatrix} = 0$ and this gives you $(2-\lambda)(6-\lambda) - 8 = 0$ or I can say this is $12 - 6\lambda - 2\lambda + \lambda^2 - 8 = 0$. So, I can say this is $\lambda^2 - 8\lambda + 20 = 0$.

So, what do we get $\lambda = -b$ and let us apply that formula $\lambda = -b \pm \sqrt{b^2 - 4ac}$ so $8 \pm \sqrt{64 - 80}$ so we can get $8 \pm \sqrt{-16}$ so $4 \pm 2i$ so you will get $4 \pm 2i$ so eigen values are $\lambda = 4 \pm 2i$. so they are conjugate complex where alpha is 4 beta is 2. So, alpha and beta both belong to $\mathbb{R} \setminus \{0\}$ they are non-0-real numbers.

Since alpha is >0 the critical point $(0,0)$ is a spiral point and it is unstable. So, we get spiral point $(0,0)$ is a spiral point and unstable.

(Refer Slide Time: 09:17)

Case V:

Theorem: The roots λ_1 and λ_2 of the characteristic equation are purely imaginary. Then the critical point of system (1) is a center.

Proof: Let $\lambda_1 = \alpha + i\beta$ and $\lambda_2 = \alpha - i\beta$, where $\alpha = 0$ and β is a non zero real number. Then, the general solution of (1) is given by

$$x = K_1 \cos(\beta t + \phi_1),$$

$$y = K_2 \cos(\beta t + \phi_2),$$

where K_1, K_2, ϕ_1 and ϕ_2 are as defined in case (4).

$$\begin{aligned} \lambda_1 &= \alpha + i\beta \\ \lambda_2 &= \alpha - i\beta \end{aligned} \quad (5)$$

$\alpha=0$ Here $\lambda_1 = i\beta, \lambda_2 = -i\beta, \beta \neq 0$

The roots of λ_1 and λ_2 of the characteristic equation are purely imaginary here we will assume that λ_1 and λ_2 are purely imaginary that is their real part is 0. We had assumed λ_1 as $\alpha + i\beta$ and λ_2 to be $\alpha - i\beta$. So, here in this case in the case 5 we will have $\alpha=0$. So, here $\lambda_1 = i\beta$ and $\lambda_2 = -i\beta$ here beta is non-0.

So, let us say $\lambda_1 = \alpha + i\beta$ $\lambda_2 = \alpha - i\beta$ where alpha is 0 and beta is a non-zero-real number. Then the general solution of 1 we had written as if you can go to the previous

case this is the final form of the solution $x = K_1 e^{\alpha t} \cos(\beta t + \phi_1)$ $y = K_2 e^{\alpha t} \cos(\beta t + \phi_2)$. So, in this case since $\alpha = 0$ x will be $K_1 \cos(\beta t + \phi_1)$ and y will be $K_2 \cos(\beta t + \phi_2)$.

We have here $X = K_1 \cos(\beta t + \phi_1)$ and $y = K_2 \cos(\beta t + \phi_2)$ where K_1 K_2 ϕ_1 and ϕ_2 are as defined in case 4.

(Refer Slide Time: 10:50)

Since the trigonometric functions in (5) oscillate indefinitely between ± 1 as $t \rightarrow +\infty$ and as $t \rightarrow -\infty$, the path do not approach $(0,0)$ as $t \rightarrow +\infty$ or as $t \rightarrow -\infty$. Clearly, x and y are periodic functions of t hence the paths are closed curves surrounding $(0,0)$. In fact they are an infinite family of ellipses.

$$\begin{aligned}
 x &= c_3 \cos \beta t + c_4 \sin \beta t \\
 y &= c_5 \cos \beta t + c_6 \sin \beta t \\
 \begin{bmatrix} x \\ y \end{bmatrix} &= \begin{bmatrix} c_3 & c_4 \\ c_5 & c_6 \end{bmatrix} \begin{bmatrix} \cos \beta t \\ \sin \beta t \end{bmatrix} \\
 A &= \begin{bmatrix} c_3 & c_4 \\ c_5 & c_6 \end{bmatrix} \\
 |A| &= c_3 c_6 - c_4 c_5
 \end{aligned}$$

Okay now let us see since the trigonometric functions in 5 trigonometric function let us look at this because when you open this what you have $\cos \beta t$ then you have $\cos \phi_1 - \sin \beta t \sin \phi_1$ okay so $\cos \beta t$ and $\sin \beta t$ they are trigonometric functions and therefore they oscillate indefinitely between $+1$ and -1 as t goes to $+\infty$ and as t goes to $-\infty$ the paths do not approach $0,0$.

As t goes to $+\infty$ or as t goes to $-\infty$ x and y are periodic functions of t because $\cos \beta t$ $\sin \beta t$ they are periodic functions so clearly x and y are periodic functions of t and the paths are closed curves surrounding $0,0$ in fact that they are infinite family of ellipses. Now how they are they are in infinite family ellipses let us see that you see x and y we had come to this form of x and y from this situation.

From this situation okay from here we came here now $\alpha = 0$ we have $x = c_2 \cos(\beta t + \phi_1)$ and $y = c_4 \sin(\beta t + \phi_2)$.

beta t y= c5 cos beta t+c6 sin beta t so let us go there. so here x= c3 cos beta t+c4 sin beta t and y=c5 cos beta t+c6 sin beta t. I can write the systems of equations as xy in the form of a matrix c3 c4 c5 c6 and we have cos beta t sin beta t okay so we have a system of equations.

And let me call this as the coefficient matrix of the system so A=c3 c4 c5 c6 determinant of A=c3 c6 -c4 c5.

(Refer Slide Time: 13:28)

Let $\alpha < 0$. Then from (4) we have $\lim_{t \rightarrow +\infty} x = 0$, $\lim_{t \rightarrow +\infty} y = 0$. Hence, all paths defined by (2) approach (0,0) as $t \rightarrow +\infty$. Now, (2) can be expressed as

$$x = e^{\alpha t} [c_3 \cos \beta t + c_4 \sin \beta t], \quad (3)$$

$$y = e^{\alpha t} [c_5 \cos \beta t + c_6 \sin \beta t],$$

where $c_3 = c_1 A_1 + c_2 A_2$, $c_4 = c_2 A_1 - c_1 A_2$, $c_5 = c_1 B_1 + c_2 B_2$, and $c_6 = c_2 B_1 - c_1 B_2$.

$$A_2 B_1 - A_1 B_2 \neq 0$$

$$A_2 B_1 \neq A_1 B_2$$

Let c_1, c_2 be real. Then, we may write the solution (3) as

$$x = K_1 e^{\alpha t} \cos(\beta t + \phi_1),$$

$$y = K_2 e^{\alpha t} \cos(\beta t + \phi_2),$$

Handwritten notes:
 $c_1, c_2 \in \mathbb{R}$
 $c_1^2 + c_2^2 > 0$
 $c_1^2 + c_2^2 = 0 \Rightarrow c_1 = c_2 = 0$
 $c_1 = c_2 = 0 \Rightarrow c_1^2 + c_2^2 = 0$
 $c_1^2 + c_2^2 > 0 \Rightarrow c_1, c_2 \neq 0$

$$A = \begin{bmatrix} c_3 & c_4 \\ c_5 & c_6 \end{bmatrix}$$

$$|A| = c_3 c_6 - c_4 c_5$$

$$|A| = (c_1 A_1 + c_2 A_2)(c_2 B_1 - c_1 B_2) - (c_2 A_1 - c_1 A_2)(c_1 B_1 + c_2 B_2)$$

$$= c_1 c_2 A_1 B_1 + c_2^2 A_2 B_1 - c_1^2 A_1 B_2 - c_1 c_2 A_2 B_2 - (c_1 c_2 A_1 B_1 + c_2^2 A_2 B_1 - c_1^2 A_1 B_2 - c_1 c_2 A_2 B_2)$$

Let us put the values of c3 c4 c5 c6 from here okay c3 c1 A1+c2 A2 or I can find here itself we have the matrix c3 c4 c5 see we have this matrix we have A=c3 c4 c5 c6 okay. So, determinant of AB found as c3 c6 -c4 c5 if you put the values of c3 c6 c4 c5. What do we get c3=c1 A1+c2 A2 c6=c2 B1-c1 B2- C4 is c2 A1-C1 A2 and c5 is c1 B1+c2 B2.

Let us multiply what do we get c1 c2 A1 B1 C2 square A2 B1 then we have C1 square A1 B2-C1 C2 A2 B2 and then we have c1 c2 A2 B2 we have- c1 square A2 B1 and then we have c2 square A1 B2 and we have -c1 c2 A2 B2 okay now what do we notice c1 c2 A1 b1 this is positive here it is negative -c1 c2 A1 B1. So, this will cancel with this okay.

And her we have -c1 c2 A2 B2 here we have+c1 c2 A2 B2 this gets cancelled with this what do we get then then A2 B1 times c2 square+c1 square okay we get A2 B1 times c2 square+c1 square and here A1 B2 times C1 square+c2square. So determinant if A is actually c1 square+c2

square*A2 B1-A1 B2 okay now let us look at the situation where determinant of A can be 0.

Determinant of A can be 0 if $c_1^2 + c_2^2 = 0$ since c_1 and c_2 are real quantities we are taking okay if $c_1^2 + c_2^2 = 0$ then $c_1 = 0$ $c_2 = 0$. Since c_1 and c_2 belong to \mathbb{R} and then c_1 and c_2 are 0 what will happen c_1 and c_2 are 0 we will get $c_3 = 0$ $c_4 = 0$ $c_5 = 0$ $c_6 = 0$ okay so c_1 $c_2 = 0$ implies c_3 c_4 c_5 and c_6 all are 0 and which implies that $x = 0$ and $y = 0$ we get a trivial situation.

So, c_1^2 and c_2^2 cannot be 0 and $-A_1 B_2$ cannot be 0 okay this cannot be 0 because we know that $R = A_2 B_1$ is not $= A_1 B_2$ this is the condition of we have on $A_1 B_1 A_2 B_2$ okay. So, this is also not 0 so determinant of A cannot be $= 0$ that is what we get that from here okay now let us go there.

(Refer Slide Time: 18:27)

Since the trigonometric functions in (5) oscillate indefinitely between ± 1 as $t \rightarrow +\infty$ and as $t \rightarrow -\infty$, the path do not approach $(0,0)$ as $t \rightarrow +\infty$ or as $t \rightarrow -\infty$. Clearly, x and y are periodic functions of t hence the paths are closed curves surrounding $(0,0)$. In fact they are an infinite family of ellipses.

Handwritten notes showing the derivation of the ellipse equation. It starts with $x = c_3 \cos \beta t + c_4 \sin \beta t$ and $y = c_5 \cos \beta t + c_6 \sin \beta t$. A matrix $A = \begin{pmatrix} c_3 & c_4 \\ c_5 & c_6 \end{pmatrix}$ is defined, and its determinant $|A| = c_3 c_6 - c_4 c_5 \neq 0$ is noted. The ellipse equation is derived as $\frac{(c_6 x - c_4 y)^2}{\Delta^2} + \frac{(c_5 y - c_3 x)^2}{\Delta^2} = 1$, where $\Delta = c_3 c_6 - c_4 c_5$. Other notes include $b^2 = a^2 c^2$ and $c^2 = c_4^2 + c_3^2$.

Okay so determinant of A cannot be 0 this is what we have found okay. We can solve this equation by (18:32). So we get $\cos \beta t$ we have determinant of the matrix xy we replace first column of the function matrix column of constant so xy c_4 or c_6 /determinant of the coefficient matrix c_3 c_4 c_5 c_6 okay this is $\cos \beta t = c_6 x - c_4 y / \Delta$ let me call the determinant of the coefficient matrix determinant of A= let us call as Δ .

So, this is Δ and $\sin \beta t =$ similarly we will have determinant c_3 c_5 c_4 c_6 . Second column will be replaced by xy/Δ and you will get $c_3 y - c_5 x / \Delta$. Now we have the values $\cos \beta t$

sin beta t we want to determine the quotient of second degree in x and y that results on elimination of t from these two quotients so $\sin^2 t + \cos^2 t = 1$.

So, we have $c_6x - c_4y$ whole square/delta square + $c_3y - c_5x$ whole square/delta square = 1 okay or we can get c_6x or $-c_4y$ whole square + $c_3y - c_5x$ whole square = delta square when you square these expressions you will get a second-degree quotient in x and y. Now this second-degree equation x and y will result in ellipse the coefficient of x and y say that is b coefficient of x square is A.

Coefficient of y square is A then $B^2 - 4AC$ if it is < 0 then it will represent the ellipse. Let us look at the coefficient of xy that we get from here so $A^2 - B^2$ so $A^2 + B^2 - 2AB$ we have the coefficient of xy in the first expression is $-2c_4c_6$ okay here the coefficient of xy is $-2c_5c_3$ okay so $b = -2c_5c_3$ okay the coefficient of xy.

We are denoting by b so this is coefficient of b so coefficient of x square is what let us denote so $c_6^2 + c_5^2$ and the coefficient of y square we are denoting by c so c will be $c_4^2 + c_3^2$. Now let us find $b^2 - 4ac$ so then what will you get if we have equation 2 and xy I think we need to take 2 objects we need not take these two that is b is the coefficient of $2xy$.

I think we need not take these two so we have this one $c_4^2 + c_6^2 + c_5^2 + c_3^2$ whole square b square means $c_4^2 + c_6^2 + c_5^2 + c_3^2$ whole square - $c_6^2 + c_5^2 + c_4^2 + c_3^2$ and this will come out to be you can see $c_4^2 + c_6^2 + c_5^2 + c_3^2$ and then 2 times $c_3^2 + c_5^2 + c_4^2 + c_6^2$ and here what we will get $c_6^2 + c_5^2$ so do we get okay c_4^2 okay $c_4^2 + c_6^2$ square.

And then $c_5^2 + c_3^2$ and then $2c_3c_4c_5c_6$ and here what we will get $c_4^2 + c_6^2$ square this will cancel with this and we will get $c_4^2 + c_5^2$ okay and here we will get $c_3^2 + c_6^2$ square and here we will get $-c_3^2 + c_5^2$ so this will cancel with this okay and what we do get now so this is $-c_3^2 + c_4^2 + c_5^2$ I think we will get it here.

Okay this can be written as $-c_3^2 + c_5^2 - c_4^2 + c_5^2$ whole square and $c_3^2 + c_6^2 - c_4^2 + c_5^2$ is delta okay -delta square

and Δ is non-0 and this is <0 so this represents $x=c_3 \cos \beta t + c_4 \sin \beta t$ and $y=c_5 \cos \beta t + c_6 \sin \beta t$ which is the summation of the linear system they represent infinite family of ellipses

(Refer Slide Time: 24:59)

Fig. 2

So here we have a node but we have unstable node

(Refer Slide Time: 25:10)

Example: Let us consider

$$\frac{dx}{dt} = 3y, \quad \frac{dy}{dt} = -x.$$

Then Eigen values are $\lambda = \pm i\sqrt{3}$.

The roots are **purely imaginary**.

\Rightarrow the critical point $(0,0)$ is a **center** and it is **stable but not asymptotically stable**.

$$A = \begin{bmatrix} 0 & 3 \\ -1 & 0 \end{bmatrix}$$

$$|A - \lambda I| = \begin{vmatrix} -\lambda & 3 \\ -1 & -\lambda \end{vmatrix} = 0$$

$$\lambda^2 + 3 = 0$$

$$\lambda = \pm i\sqrt{3}$$

Okay we have a center we have a center out of this situation we have a center but it is stable but not asymptotically stable so we have this situation let us consider $dx/dt=3y$ $dy/dt=-x$ so here we can see the matrix A is $0 \ 3$ and $-1 \ 0$ a is 0 b is 3 c is -1 d is 0 so we get determinant of $A - \lambda I = -\lambda^2 - 3 = 0$ so we get $\lambda^2 + 3 = 0$ so $\lambda = \pm i\sqrt{3}$

root 3.

So, the roots are purely imaginary so the critical point $0,0$ as we have already just not discussed the critical point $0,0$ in the center it is stable but not asymptotically stable.

(Refer Slide Time: 26:14)

And this is the figure here okay you can see $0,0$ center and the it is stable but not asymptotically stable.

(Refer Slide Time: 26:28)

<i>Nature of roots λ_1 and λ_2 of characteristic equation (*)</i>	<i>Nature of critical point $(0,0)$ of linear system (1)</i>	<i>Stability of critical point $(0,0)$</i>
conjugate complex but not purely imaginary	Spiral point	Asymptotically stable if real part of roots is negative; unstable if real part of roots is positive
purely imaginary	Center	Stable but not asymptotically stable

So, let us consider the first the case where λ_1 and λ_2 are both conjugate complex roots but they are not purely imaginary that is $\alpha \neq 0$. We have seen that in this case $0,0$

is a spiral of point and we have seen that if α is negative then we had the stability point $0,0$ is asymptotically stable but if α is positive then point $0,0$ is unstable.

And just now we discussed the case that λ_1 and λ_2 are purely imaginary that is $\pm i\beta$ in that case we had the critical point $0,0$ as a center it is stable but not asymptotically stable.
Thank you very much for your attention.
