**Lecture - 30**  
**Green's Function and its Application- I**

Hello friends, welcome to this lecture. In this lecture, we will discuss the method of green functions to solve the non-homogenous boundary value problem with the help of Green's function. First of all, we should discuss the what is Green's function and what are the properties of green function and how to construct the Green's function and then with the help of Green's function how we can solve the-- how we can handle the non-homogenous boundary value problem.

In some case, we can get the solution in close form and in some cases we will get the solution in terms of say some kind of equation which is known as integral equation, so we will consider all these things in this lecture and the lecture afterward. So first let us start the first theorem.

**(Refer Slide Time: 01:23)**

Green functions

**Theorem** Let the homogeneous problem

$$p_0(x)y'' + p_1(x)y' + p_2(x)y = 0 \quad (35)$$

with

$$\begin{cases} l_1[y] = a_0y(\alpha) + a_1y'(\alpha) + b_0y(\beta) + b_1y'(\beta) = 0 \\ l_2[y] = c_0y(\alpha) + c_1y'(\alpha) + d_0y(\beta) + d_1y'(\beta) = 0 \end{cases} \quad (36)$$

have only the trivial solution. Then Green function exists for (35),(36) and there exists a unique solution  $y(x)$  of the nonhomogeneous problem

$$\begin{cases} p_0(x)y'' + p_1(x)y' + p_2(x)y = r(x) \\ l_1[y] = a_0y(\alpha) + a_1y'(\alpha) + b_0y(\beta) + b_1y'(\beta) = 0 \\ l_2[y] = c_0y(\alpha) + c_1y'(\alpha) + d_0y(\beta) + d_1y'(\beta) = 0 \end{cases}$$

Let us that the homogenous problem that is  $p_0(x)y'' + p_1(x)y' + p_2(x)y = 0$  along with the two boundary condition  $l_1[y]$  that is  $a_0y(\alpha) + a_1y'(\alpha) + b_0y(\beta) + b_1y'(\beta) = 0$  and  $l_2[y]$  that is  $c_0y(\alpha) + c_1y'(\alpha) + d_0y(\beta) + d_1y'(\beta) = 0$ . So here we have a homogenous equation with two set of boundary conditions and

here we are assuming that this  $l_1$  and  $l_2$  are not linearly dependent boundary condition. So it means that this  $a_1, b_1$  is not a scalar multiple of  $c_1, d_1$ .

And here we assume that this homogenous problem along with the boundary conditions has a trivial solution then Green function exists for this set of equation and there exists a unique solution for the non-homogenous problem  $p(x)y'' + p_1(x)y' + p_2(x)y = r(x)$  with this homogenous boundary conditions. So idea is that here we have homogenous equation along with homogenous boundary condition.

And if this has trivial solution then Green function exists and with the help of Green function we can find out a unique solution of the non-homogenous problem this along with the boundary condition and unique solution is given by the following formula that is  $y_p = \int_{\alpha}^{\beta} G(x,t)r(t)dt$ . Here  $\alpha, \beta$  is the interval in which we are finding the solution.

**(Refer Slide Time: 02:56)**

can be represented by

$$y_p = \int_{\alpha}^{\beta} G(x,t)r(t)dt,$$

where  $G(x,t)$  is a Green function for the problem (35), (36).

So this means that your homogenous problem is given in terms of this  $\alpha, \beta$  here. So here I am denoting the unknown function is  $y$  and it is function of  $x$  and  $x$  is lying between  $\alpha$  and  $\beta$ . So here we will try to prove this later on but first we discuss the property of this equation. So here  $y_p = \int_{\alpha}^{\beta} G(x,t)r(t)dt$ . So if we know this function  $G(x,t)$  which is known as Green functions for the problem 35 and 36. So if we know the Green function then we can find out the solution of the non-homogenous problem that is going to be unique.

(Refer Slide Time: 03:57)

Properties of Green Function

- ✓(i)  $G(x, t)$  is continuous in  $[\alpha, \beta] \times [\alpha, \beta]$ .
- (ii)  $\partial G(x, t)/\partial x$  is continuous in each of the triangles  $\alpha \leq x \leq t \leq \beta$  and  $\alpha \leq t \leq x \leq \beta$ . Moreover,

$$\frac{\partial G}{\partial x}(t^+, t) - \frac{\partial G}{\partial x}(t^-, t) = \frac{1}{p_0(t)}$$

where

$$\frac{\partial G}{\partial x}(t^+, t) = \lim_{x \rightarrow t} \frac{\partial G}{\partial x}(x, t) \quad \text{and} \quad \frac{\partial G}{\partial x}(t^-, t) = \lim_{x \rightarrow t} \frac{\partial G}{\partial x}(x, t)$$

- (iii) For every  $t \in [\alpha, \beta]$ ,  $z(x) = G(x, t)$  is a solution of the differential equation (35) in each of the intervals  $[\alpha, t)$  and  $(t, \beta]$ .
- (iv) For every  $t \in [\alpha, \beta]$ ,  $z(x) = G(x, t)$  satisfies the boundary conditions (36).

So let us first discuss the properties of Green functions. So here some properties of Green function, some property is that  $G(x, t)$  is continuous in  $[\alpha, \beta] \times [\alpha, \beta]$ . So here  $x$  is in  $[\alpha, \beta]$  and  $t$  is in  $[\alpha, \beta]$ . So  $G(x, t)$  is continuous in this rectangle. Now,  $\partial G/\partial x$  is continuous in each of the triangles that is  $x \leq t$  and  $t \leq x$ . And  $\alpha \leq t \leq \beta$ .

So it means that here it is basically continuous in each of the triangles. And it also at the diagonal term, let me write it here. This is say  $\alpha, \beta$  and this is  $\alpha, \beta$  here, so here we have this and then we have the triangles here. So we have two triangles. So in each of the triangles you can say that your  $\partial G/\partial x$  is continuous and at the diagonal term we have jump this continuity that is  $\partial G/\partial x(t^+, t) - \partial G/\partial x(t^-, t) = 1/p_0(t)$ .

So here we discuss the properties of Green function. So first property is that  $G(x, t)$  is continuous in this rectangle  $[\alpha, \beta] \times [\alpha, \beta]$ . So here let us say that here we have this axis represent the  $x$  and this represent the  $t$  here, so  $x$  is from  $[\alpha, \beta]$  and  $t$  is also from  $[\alpha, \beta]$ , so we are writing it here, so it is somewhere here so  $x$ -axis and  $t$ . So this represent  $\alpha$  and this represent your  $\beta$ .

So now what is given here that in this whole activity your  $G(x, t)$  is continuous. And also second property is that  $\partial G/\partial x$  is continuous in each of the triangles, the first triangle is  $\alpha \leq x \leq t \leq \beta$

$x < \text{or} = t$  that is this here. So here  $\frac{dg}{dx}$  is continuous in this triangle and also in this triangle that is  $\alpha < \text{or} = t < \text{or} = x$ . So here your this in this region your  $\frac{dg}{dx}$  is continuous. And when we look at when we look at the diagonal term of this triangle then rectangle then we have this jump discontinuity.

Means in each of the separate region  $\frac{dg}{dx}$  is continuous but at the diagonal it has a jump discontinuity; jump discontinuity is given by quantity one upon  $p_0 t$ . So it is given by  $\frac{dg}{dx}$  from  $t^+$ ,  $t - \frac{dg}{dx} \big|_{t=t^+} = 1$  upon  $p_0 t$ . So here, so it means that if you calculate the  $\frac{dg}{dx}$  here in this reason –  $\frac{dg}{dx}$  in this reason then it has the jump discontinuity of measure 1 upon  $p_0 t$ .

So here  $\frac{dg}{dx} \big|_{t^+}$  is defined as that limit extending to  $t$   $x$  is coming from the positive side of  $t$  that is  $x$  is coming from this region. So here your  $x$  is bigger than  $t$ . So  $\frac{dg}{dx} \big|_{t^+}$ ,  $t$  is the derivative of  $\frac{dg}{dx}$ , when  $x$  is reaching to this diagonal term. And  $\frac{dg}{dx} \big|_{t^-}$  is when you reaching towards the diagonal term from this region then this represent  $\frac{dg}{dx} \big|_{t^-}$ ,  $t$  is limit extending to  $t$  when  $x < t$   $\frac{dg}{dx} \big|_{t^-}$ .

So here one is  $\frac{dg}{dx}$ ,  $G(x,t)$  is continuous  $\frac{dg}{dx}$  continuous in this triangle and on the diagonal term it has a jump discontinuity and it is given by 1 upon  $p_0 t$  and next property is that for every element in  $\alpha$ ,  $\beta$  your  $z(x) = G(x,t)$  is a solution of the differential equation in each of the interval  $\alpha$ ,  $t$  and  $t$ ,  $\beta$ . So it means that  $G(x,t)$  is a solution of the differential equation and the region  $\alpha$   $t$  and  $t$ ,  $\beta$ .

So at  $t$  it may not be a solution here. For every  $t$  and  $\alpha$ ,  $\beta$   $z(x) = G(x,t)$  satisfies the boundary condition. So first of all it is the solution of the differential equation when  $t$  is not equal to  $x$  and it satisfy the boundary condition which we have provided along with the equation.

**(Refer Slide Time: 08:46)**

## Green's Function for Self-adjoint Linear Differential Equations

Let us consider the construction of Green's function for a second order differential equation of the form:

$$(\rho_0(x)y')' + p_2(x)y = 0, \quad (37)$$

where  $\rho_0(x) \neq 0$  on  $[a, b]$  and  $\rho_0(x) \in C^1[a, b]$  with boundary conditions

$$y(a) = y(b) = 0 \quad (38)$$

Let  $y_1(x)$  be a solution of (37) defined by the initial conditions

$$y_1(a) = 0, \quad y_1'(a) = \alpha \neq 0. \quad (39)$$

This solution need not necessarily satisfy the second boundary condition so assume  $y_1(b) \neq 0$ . But functions of the form  $C_1 y_1(x)$  are solution of (37) satisfying  $y(a) = 0$ , where  $C_1$  is an arbitrary constant.

So now let us now construct the Green function for self-adjoint Linear Differential Equation. And so let us consider the construction of Green's function for a second order differential equation of the form  $p_0(x)y'' + p_2(x)y = 0$ , where  $p_0(x)$  is non-zero on this interval  $A, B$  and  $p_0(x)$  is basically a  $C^1$  function means continuous differential function with the boundary condition that  $y(a) = y(b) = 0$ .

So basically it is a Sturm-Liouville problem which we are considering. So it is a self-adjoint problem along with boundary condition. We want to find out the Green function for this particular boundary value problem. So let  $y_1(x)$  be a solution of this equation (37) defined by the initial condition. We already know that if we have some initial condition then this is an initial value problem and it must have a same solution because your coefficients are continuous in this close interval  $A, B$ .

So by existence uniqueness of initial value problem this must have a solution, let us denote that solution as  $y_1(x)$  and it satisfy the initial condition  $y_1(a) = 0$  and  $y_1'(a) = \alpha$  where  $\alpha$  is some non-zero value. So this solution need not necessarily satisfy the second boundary condition that is here  $y_1(b)$  may not be 0 but if  $y_1(b) = 0$  then we have already solved our homogenous problem and we need not to consider for anything more.

So but here it may not always possible to have solution for which  $y_1(B) \neq 0$ . But any multiple of this  $y_1$  will have this property that  $c_1 y_1(x)$  be a solution of this equation that is Sturm-Liouville equation and it also satisfy the initial condition that is  $y(A) = 0$ . So any multiple of  $y_1$  will have this particular property.

**(Refer Slide Time: 10:52)**

Similarly we find the non zero solution  $y_2(x)$  of (37) such that:

$$y_2(b) = 0, \quad y_2'(b) \neq 0 \quad (40)$$

This same condition will be satisfied by  $C_2 y_2(x)$ .

We now find Green's function in the form

$$G(x, \xi) = \begin{cases} C_1 y_1(x), & \text{for } a \leq x < \xi; \\ C_2 y_2(x), & \text{for } \xi \leq x \leq b. \end{cases} \quad (41)$$

Since  $G(x, \xi)$  is continuous at  $x = \xi$ ,

$$C_1 y_1(\xi) = C_2 y_2(\xi). \quad \checkmark \quad \frac{\partial G}{\partial x} \Big|_{\xi^+} - \frac{\partial G}{\partial x} \Big|_{\xi^-} = \frac{1}{p(\xi)}$$

Moreover,

$$C_2 y_2'(\xi) - C_1 y_1'(\xi) = 1/p_0(\xi). \quad \checkmark$$

Now look at another solution  $y_2(x)$  which satisfy the equation and the other boundary condition that is  $y_2(B) = 0$ . Here we can assume that  $y_2'(B)$  is some non-zero value so that it is not a trivial solution, because if you take  $y_2(B) = 0$  and  $y_2'(B) = 0$  then we have only a trivial solution on the homogenous problem. So here we assume that  $y_2'(B) \neq 0$ . This same condition will be satisfied by any multiple of  $y_2$ .

So now we have, we propose our Green function in the following form that  $G(x, \xi) = C_1 y_1(x)$ , for  $x$  defined from  $a$  to  $\xi$  and it is  $C_2 y_2(x)$  when  $\xi$  is from  $x$ — $x$  is from  $\xi$  to  $b$ . So here we if you look at this you have  $x$  and you have  $\xi$  here and let us write it  $a$  to here this is  $x = \xi$  here. So  $x$  from  $A$  to  $\xi$  so from this here you have  $C_1 y_1(x)$  and here you have  $C_2 y_2(x)$  and you need to find out this  $C_1$  and  $C_2$  based on the properties of Green function which we have assumed here.

So first property we have assumed that  $G(x, \xi)$  is continuous at  $x = \xi$  so on this diagonal it is continuous so it means that  $C_1 y_1(\xi) = C_2 y_2(\xi)$ . So if we come from the left or the right the value must be equal. So if  $C_1 y_1(\xi) = C_2 y_2(\xi)$  because here we are approaching from this side

and approaching from this side at  $x=\psi$  it must be equal. So  $C_1 y_1 \psi = C_2 y_2 \psi$ . That is from the continuity of  $G(x,t)$ .

Now we also assume that  $\frac{dg}{dx}$  is continuous in triangle but has a jump discontinuity in the diagonal term that is  $x=\psi$  here. So here we simply say that  $\frac{dg}{dx}$  at say  $\psi +$  -  $\frac{dg}{dx}$  at  $\psi - = 1$  upon the coefficient term that is  $p_0$  here, so this is. So  $\frac{dg}{dx}$  when  $\psi +$  so  $\psi +$  is the region  $x$  is bigger than  $\psi$  so it means that this represent this  $\psi +$  region. So  $C_2 y_2$  dash at point  $\psi$  so  $C_2 y_2 \psi - C_1 y_1 \psi = 1$  upon  $p_0 \psi$  here.

So we have these two conditions.

**(Refer Slide Time: 13:36)**

Rewriting the last two equations as a system of equation in  $C_1$  and  $C_2$ , we observe that

$$W[y_1(x), y_2(x)]|_{x=\xi} = W(\xi) \neq 0.$$

Which implies that

$$C_1 = \frac{y_2(\xi)}{p_0(\xi)W(\xi)}, \quad C_2 = \frac{y_1(\xi)}{p_0(\xi)W(\xi)} \quad (42)$$

Since  $y_1$  and  $y_2$  are solutions of  $Ly = 0$ , therefore, from Lagrange's identity  $y_1(p_0 y_2)' - y_2(p_0 y_1)' = \frac{d}{dx}[p_0 W(y_1, y_2)] = 0$ . Hence,  $[p_0 W(y_1(x), y_2(x))]|_{x=t} = p_0(t) W(t) = A$  for all  $t \in [a, b]$ . Here  $A$  is a constant. Hence, we get

$$G(x, \xi) = \begin{cases} \frac{y_1(x)y_2(\xi)}{p_0(\xi)W(\xi)} & a \leq x \leq \xi; \\ \frac{y_1(\xi)y_2(x)}{p_0(\xi)W(\xi)} & \xi \leq x \leq b. \end{cases}$$

*Handwritten notes in red:*  
 $y_1(a)=0, y_1(b) \neq 0$   
 $y_2(a) \neq 0, y_2(b)=0$   
 $A = W(t) + t \in [a, b]$   
 $G_1(x, \xi) = G_2(\xi, x)$

Now when you simplify these two thing to find out  $C_1$  and  $C_2$  because if you know  $C_1$  and  $C_2$  then our Green function is known to us. So now we already have rewriting the last two equations as a system of equation in  $C_1$  and  $C_2$ , we observe that this Wronskian of  $y_1$  and  $y_2$  that is  $y_1 y_2$  dash -  $y_2 y_1$  dash is basically Wronskian of  $y_1$  and  $y_2$  at the point  $x=\psi$  is non-zero  $y$  because here your  $y_1$  and  $y_2$  are linearly independent solution.

How we say that if you look at we have already assumed that  $y_A=0$  but  $y_B$  is not equal to 0. And we have this is  $y_1$  and we have assumed our  $y_2$   $B$  is something which is satisfying 0 value at point  $B$ . So  $y_1 B$  is non-zero and but  $y_2 B$  is 0, so from this we can say that  $y_1$  and  $y_2$  are linearly independent to each other. So it means that Wronskian is going to be non-zero and let us

call this Wronskian is  $w(\psi)$  here and with the help of this Wronskian we can find  $c_1$  as  $y_2(\psi)$  upon  $p_0(\psi) w(\psi)$  and  $c_2$  as  $y_1(\psi)$  upon  $p_0(\psi) w(\psi)$  would have  $\psi$ .

In fact, it is basically what, you can write it here as this equation you can write it here that  $c_1$ ,  $c_2 =$  here 0 and 1 upon  $p_0(\psi)$  here and here  $c_1 c_2$  means you can write it here  $y_1(\psi)$  and here it is  $-y_2(\psi)$ , here it is what  $-y_1(\psi)$  dash  $\psi$  here  $y_2(\psi)$  dash  $\psi$ . If we write down these two equation in terms of metrics equation  $e x = b$  kind of thing. So here from first equation we can write  $y_1(\psi) - y_2(\psi) c_1 c_2 = 0$ . And last equation can be written in this term  $-y_1(\psi) c_1 + c_2 y_2(\psi) c_2 = 1$  upon  $p_0(\psi)$ . So we can write down these things in terms of this.

Now, if you look at the determinant of this is basically the Wronskian up 1 and  $y_2$  at the point  $\psi$  and we have assumed that since  $y_1$  and  $y_2$  are linearly dependent so this Wronskian is going to be non-zero throughout the interval. So with the help of Wronskian we can write down this solution  $c_1$  and  $c_2$  and here we have to note down one thing that this the denominator this  $p_0(\psi) w(\psi)$  is going to be a constant value.

For that we utilize the Lagrange's Identity and we note that  $y_1$  and  $y_2$  are solution of  $ly=0$ . And therefore from Lagrange's Identity  $y_1 p_0 y_2 - y_2 p_0 y_1$  dash whole dash =  $d/dt p_0 w y_1 y_2$ . Now we already know that  $y_1 y_2$  is basically solution of this so this is going to be 0 here. So we can write that  $p_0 w y_1 y_2$  is basically a constant value. So  $p_0 w y_1 y_2$  at any point  $x=t$  which I denote as  $w(t)$  is going to be a constant value.

So that is what, so if using this constant value, I can write  $p_0 w = A$ , so for all values of  $x$ . So here whether you write  $p_0(\psi) w(\psi)$  or you simply write any constant  $A$ . So here any constant means the value given at  $w$  at  $t$ . So  $w$  at  $t$  is given a some constant. So here either you write this or you simply replace this quantity by constant  $A$  where  $A$  is basically Wronskian of  $t$  at any point  $t$  in this interval  $A$  to  $B$ . Is that okay? So  $G(x, \psi)$  is not known to us.

So it satisfies all the properties of Green function. And moreover this also satisfy one very important property that is  $G(x, \psi) = g(\psi, x)$ . So here when you interchange the rule of  $x$  and  $\psi$  then we have symmetric. So  $G(x, \psi) = g(\psi, x)$ , so here it is a symmetric. And this symmetricity is

coming from the fact that we are considering the self-adjoint second order linear differential equation. So because of self-adjointness the Green function coming out to be a symmetrical function. If we consider non-self-adjoint or any type of equation, then this symmetricity may not be preserved.

**(Refer Slide Time: 18:27)**

**Note 1**

The solutions  $y_1(x)$  and  $y_2(x)$  of equation (37) that we have chosen are linearly independent by virtue of the assumption that  $y_1(b) \neq 0$

**Note 2**

The BVP for a second order equation of the form

$$y''(x) + p_1(x)y'(x) + p_2(x)y(x) = 0 \quad (44)$$

$$y(a) = A, \quad y(b) = B \quad (45)$$

reduces to (37) as follows

- (1) Equation (44) can be reduced to the self adjoint form by multiplying  $p(x) = e^{\int p_1(x) dx}$  in (44).

So now here this is one some remark, first remark is that solution  $y_1$  and  $y_2$  of equation 37 which we have chosen are linearly independent by because we have assumed that  $y_1(b) \neq 0$  and  $y_2(b) = 0$ . So that we have already noted down. Now second remark which we wanted to note it here, that we have given the method of constructing the Green function for self-adjoint equation.

But if it is not self-adjoint then we have already discussed that how a given linear ordinary differential equation can be converted into a self-adjoint linear ordinary differential equation. And again I am repeating that if we have equation  $y'' + p_1(x)y' + p_2(x)y = 0$  here purposefully I am denoting the coefficient of  $y'$  as  $p_1$ . And along with the boundary condition  $y(a) = A$  and  $y(b) = B$ .

Here also I am assuming that we have a non-homogenous boundary condition. So first thing is that how to retain the self-adjointness of this equation and that we can do by multiplying function

e to the integration of  $p_1 x dx$ . If you multiply this, then this 44 can be converted into self-adjoint form. And now look at the non-homogenous boundary condition.

**(Refer Slide Time: 19:51)**

(2) The conditions (45) reduces to zero conditions by a linear change of variables

$$z'(x) = y'(x) - \frac{B-A}{b-a} \quad z''(x) = y''(x)$$

$$z(x) = y(x) - \frac{B-A}{b-a}(x-a) - A \quad \checkmark$$

The linearity of (44) is preserved to this change but unlike equation  $Ly = 0$ , we now obtain the non-homogeneous equation  $Lz = f(x)$  where

$$f(x) = - \left[ A + \frac{B-A}{b-a}(x-a) \right] p_2(x) - \frac{B-A}{b-a} p_1(x) \quad \checkmark$$

$$y'' + p_1(x)y' + p_2(x)y = 0$$

$$z'' + p_1(x) \left[ z'(x) + \frac{B-A}{b-a} \right] + p_2(x) \left[ z(x) + \frac{B-A}{b-a}(x-a) - A \right] = 0$$

That can be rectified by a linear change of variable that is if we assume  $z = yx - b - c$  upon  $b - A * x - A - A$ , then this  $z$  has  $a$ , infact what we have done here, we have considered  $z$  of  $x = y$  of  $x + ax + b$ , sorry I have to use some other variable because  $a$  and  $b$  are already given here. So let us assume this as say  $\alpha$  and  $\beta$ .  $\alpha, \beta$  I am not taking. So here let us say that  $\alpha x + \beta$ . We need to find out  $\alpha, \beta$  such that  $z$  of  $a = 0$  and  $z$  of  $b = 0$ .

So using this you can find out  $\alpha$  and  $\beta$ . So if you look at this  $z = y$  of  $a = a + \alpha a + \beta a - b = 0$ , so  $\beta = b + \alpha a - b - \beta a$ . So by using this you can find out the value of  $\alpha$  and  $\beta$  here. That is what I have written here. That you can find out  $\alpha, \beta$  and it is given by this. So  $z$  of  $x = y$  of  $x - b - a$  upon  $B - a$  divided by  $b - a$   $x - a$ , so if you use this, then we can change our boundary condition to homogeneous boundary condition.

But if you do this then our problem will also change. So problem initially it is given as  $ly = 0$ , is now changed to something like  $lz = f$  of  $x$ . so how we can look at here.  $z$  of  $x$  is given by this. So you can write down  $z$  of  $x$  as  $y$  dash  $x$  - some quantity let us say this \* this is simply 1, so you will get this quantity that is  $b - A / b - a$ . And if you look at  $z$  double dash  $x$ , then we have  $y$  double dash  $x$ . Is it okay?

Then using these values, if you put it back then what you will get. Let me write it here. So your equation is basically what equation is this,  $y'' + p_1 x y' + p_2 x y = 0$ . I'm just using the values of  $y''$ . So  $y''$  is  $z'' + p_1 x$ . Now  $y'$  is basically this so it is  $z' + p_1 x$ . So  $y$  is basically this  $z + p_1 x^2/2 + y_0$ . I think this will be + here. So here we have this.

And if you simplify what you will get. You will get here  $z'' + p_1 x z' + p_2 x z = 0$ . So this term we are taking  $+ p_2 x z$ , and what left we are receptive they are, so here we have this quantity, first thing is this that  $p_2 x$  when you shift it there, then we have a negative sign so here  $p_2$  within bracket we have  $B-a/b-a$  and  $x-a$  so this is  $-a$ , right. So we are taking this term along with these two terms. So  $-p_2$  \* within bracket what you have.

And  $-p_1 x$  we are considering now this term,  $p_1 x B-a$  upon  $b-a$ . So that is what we have written. So it means that now our problem is. This is what, this is  $Lz$  and we call this quantity as some function of  $x$ . So now by changing the non-homogenous boundary condition to homogenous boundary condition, we have used this transformation but this transformation changes the boundary condition to homogenous boundary condition but it also changes the homogenous equation to a non-homogenous equation.

So here what we have done is that we have considered the homogeneous equation with non-homogenous boundary condition. When we do this change, then we have non-homogeneous equation with homogeneous boundary condition. That is what we have seen here. So now we should know how to solve this non-homogenous equation with homogeneous boundary condition.

## Example

### Example 22

Find the Green function of the problem  $y'' + y = 0$ ,  $y(0) = y(\pi/2) = 0$ . Then, solve the boundary value problem

$$y'' + y = 1 + x, \quad y(0) = y(\pi/2) = 1. \quad (46)$$

**Solution:** General solution of the given problem is

$$y(x) = c_0 \cos x + c_1 \sin x. \quad \checkmark$$

Now,  $y(0) = y(\pi/2) = 0$  implies that  $y(x) = 0$ . Hence, Green function exists.  
Consider

$$G(x, t) = \begin{cases} A \cos x + B \sin x, & 0 \leq x \leq t; \\ C \cos x + D \sin x, & t \leq x \leq \pi/2. \end{cases} \quad (47)$$

So now let us consider one simple example based on whatever we have just presented. So find the Green function of the problem  $y'' + y = 0$  at the boundary condition  $y = y(\pi/2) = 0$  and then we want to solve the non-homogeneous problem that is  $y'' + y = 1 + x$  and non-homogeneous boundary condition as well that is  $y(0) = 1$  and  $y(\pi/2) = 1$ . So we start with homogeneous problem and with the help of Green function we try to solve the non-homogeneous equation along with non-homogeneous boundary condition here.

So first let us first find out the Green function. So to find out the Green function we have to look at the homogeneous equation along with homogeneous boundary condition and if you solve that, we have  $y(x) = c_0 \cos x + c_1 \sin x$ . and if you look at these boundary condition, then  $y(0) = y(\pi/2) = 0$ , we have only a trivial solution.

So it means that homogeneous problem with homogeneous boundary condition has only trivial solution so by the first theorem which we discussed in the beginning of the lecture that in this case we have Green function exist and with the help of Green function we can solve the non-homogeneous problem, okay. So, first we have Green function exists and now we want to find out the Green function.

Now please note down here that the homogeneous equation is given in self-adjoint form, so we can easily find out the  $G(x, t)$  with the procedure we have already discussed so  $G(x, t) = a \cos x + b$

$\sin x$  where  $x$  is  $<$  or  $=$  to  $t$ , look at this term only and  $c \cos x + d \sin t$  when  $t$  is  $<$  or  $=$   $x$ . So we have two reasons,  $x < \text{or } = t$  and  $t > \text{or } = x$ . So here we need to fix your  $a, b, c, d$  depending on the properties of this.

So here first you have that this  $a \cos x + b \sin x$  must satisfy the boundary condition given at the point  $x = 0$ . And  $c \cos x + d \sin x$  satisfy the boundary condition given at the point  $x = \pi/2$ . So here we already know that for each  $t$  from  $0$  to  $\pi$  by  $2$ ,  $y(x) = G(x, t)$  is a solution of the differential equation and satisfies the boundary condition so  $y(0) = 0$  implies that  $a = 0$  and  $y(\pi/2) = 0$  implies that  $d = 0$ .

So here if you look at this, in this domain  $x = 0$  is coming so the boundary so  $G(x, t)$  will satisfy the boundary condition at  $x=0$  by this function and  $G(x, t)$  will satisfy the other boundary condition defined at  $\pi/2$  by this function.

**(Refer Slide Time: 28:05)**

Since for each  $t \in [0, \pi/2]$ ,  $y(x) = G(x, t)$  is a solution of the differential equation and satisfies the boundary conditions. So,  $y(0) = 0$  implies that  $A = 0$  and  $y(\pi/2) = 0$  implies that  $D = 0$ . Thus (47) reduces to

$$G(x, t) = \begin{cases} B \sin x, & 0 \leq x \leq t; \\ C \cos x, & t \leq x \leq \pi/2. \end{cases} \quad (48)$$

Since Green function is continuous on  $[0, \pi/2]$  so, we have

$$B \sin t = C \cos t \quad x=t \quad -(C \sin t - B \cos t) = 0 \quad (49)$$

for each  $t \in [0, \pi/2]$  and by using  $\frac{\partial}{\partial x} G(x, t) \Big|_{x=t^-} = \frac{1}{p(t)}$ , we get

$$C \sin t + B \cos t = -1 \quad (50)$$

Solving (49) and (50), we get  $B = -\cos t$  and  $C = -\sin t$ . So, Green function becomes

$$G(x, t) = \begin{cases} -\cos t \sin x, & 0 \leq x \leq t; \\ -\sin t \cos x, & t \leq x \leq \pi/2. \end{cases}$$

So it means that you can find out that  $y(0) = 0$  implies that  $a = 0$  because this is the solution which contains the reason  $x = 0$ , so here we will get  $a = 0$ . And similarly  $y(\pi/2) = 0$  means your  $d = 0$ . So our  $G(x, t)$  is now reduced to this that is  $G(x, t) = b \sin x$  when  $x$  is lying between  $0$  to  $t$  and  $c \cos x$  when lying between  $t$  to  $\pi/2$ . So now we have to find out this  $b$  and  $c$ . So what we have utilized so far. We have utilized so far the  $G(x, t)$  is a solution of the differential equation.

So with the help of this we have constructed our  $G(x, t)$  and that  $G(x, t)$  satisfies the boundary condition. So with the help of boundary condition we have fixed our  $a$  and one of the constant. Now let us fix the other remaining constants  $b$  and  $c$ . and for that we have two conditions that  $G(x, t)$  is continuous and  $G(x, t)$  has a jump discontinuity. So let us say that since Green function is continuous on  $0$  to  $\pi/2$ .

So let us check the continuity at  $x = t$ , so it means that if we come from this reason or this reason, we will get the same value. So  $b \sin t$  has to be equal to  $c \cos t$ . And then the other condition that it has the jump discontinuity so it means that  $\frac{dg}{dx}$  from  $t^+$  to  $t^- = 1$  upon  $p t$ . So if you look at  $\frac{dg}{dx}$  from  $t^+$ , so  $t^+$  is this. So here you can see that  $-c \sin t$ , we are looking at  $x = t$ ,  $-b \cos t = 1$  upon  $p t$ ,  $p t$  is basically  $1$  here, so it is  $1$ .

So we can simplify this and write  $c \sin t + b \cos t = -1$ . This minus we are shifting here. So we are with equation 49 and equation 50. And with the help of this we can find out the constant  $b$  and  $c$ . So when we find out the constant  $b$  and  $c$  it is coming out to minus  $\cos t$  and minus  $\sin t$ . And with the help of  $b, c$  now we are able to write down the Green function that is  $G(x, t)$  is  $-\cos t \sin x$  from  $x$  from  $0$  to  $t$  and  $-\sin t \cos x$  when  $x$  is from  $t$  to  $\pi/2$ .

And you can see that your symmetricity is preserved here. So here it means that  $G(x, t)$  can be written as replaced by  $G(x, t)$ . Anyway. So now let us fix the boundary condition as well. So we have not fixed the boundary condition, so for fixing the boundary condition—

**(Refer Slide Time: 30:47)**

Now, consider  $z(x) = y(x) - 1$ ; then (46) becomes

$$z'' + z = x, \quad z(0) = z(\pi/2) = 0.$$

Now, solution of the above differential equation is

$$z(x) = \int_0^{\pi/2} G(x,t)f(t)dt = \int_0^x G(x,t)t dt + \int_x^{\pi/2} G(x,t)t dt$$

$$= -\cos x \int_0^x t \sin t dt - \sin x \int_x^{\pi/2} t \cos t dt.$$

On solving this, we get  $z(x) = x - \frac{\pi}{2} \sin x$ . Since,  $z(x) = y(x) - 1$ , so we have

$$y(x) = 1 + x - \frac{\pi}{2} \sin x.$$

$$y'' + y = 1 + x, \quad y(0) = 1, \quad y(\pi/2) = 1$$

So let us assume that  $z(x) = y(x) - 1$ . In fact, you can assume  $z(x) = \alpha x + \beta$  and you can simplify your  $\alpha$  and  $\beta$  and it is coming out that  $\alpha$  is coming out to be zero and  $\beta$  is  $=$  minus 1. So  $z(x) = y(x) - 1$ . Now with the help of this reduce your non-homogeneous problem that is  $y'' + y = 1 + x$  and these boundary conditions. So these boundary conditions are already fixed.

Now  $z(0) = 0$  and  $z(\pi/2) = 0$  and if you fix this then you have  $z'' + z = x$  and with this now if you look at the homogeneous boundary condition and a non-homogeneous equation. And we already know that the solution is given by  $z(x) = \int_0^{\pi/2} G(x,t)f(t)dt$ , where  $f(t)$  represents the right hand side of this equation and here your  $f(t)$  is basically  $t$ . so  $z(x) = \int_0^{\pi/2} G(x,t)t dt$ .

Now here, depending on the domain you have to use different values of  $G(x,t)$ . So you can simply write it,  $\int_0^x G(x,t)t dt + \int_x^{\pi/2} G(x,t)t dt$ . So we have to look at in this reason when here, sorry, I have to write  $\int_0^x$ . so let me write it here,  $\int_0^x$ . So here  $0 < t < x$  and  $x < t < \pi/2$ . So here you look at that  $t < x$ . So in this way  $t < x$  means  $x > t$ . So if you look at  $x > t$  means  $-\sin t \cos x$ . so here we use minus  $\sin t \cos x$ .

So here we are using this value. So  $G(x,t)$  is minus  $\sin t \cos x$ , here we are using it. And here in this way, your  $t$  is bigger than  $x$  means  $-\cos t \sin x$ . so this will be used here. So here we use this

part, minus  $\cos t \sin x$ . so  $-\cos t$  will go outside and  $\sin x$  is taken outside because integral is with respect to  $t$ . when you simplify you will get your solution  $z_x = x - \frac{\pi}{2} \sin x$ .

I am not doing this integration because it is simple integration. You can do it.

So once we have  $z$  of  $x$  then since we already know  $z_x = y_x - 1$ , so we can have our solution of the problem that is  $y_x = 1 + x - \frac{\pi}{2} \sin x$  and this is the solution of the problem by  $y'' + y = 1 + x$  with condition  $y(0) = 1$  and  $y(\frac{\pi}{2}) = 1$ . So what we have seen in this example is how to construct a Green function and with the help of green function how to solve a non-homogeneous equation with non-homogeneous boundary value problem.

So, here I will conclude our lecture and in next lecture we will discuss some more result on green function and discuss some more example based on this. So thank you for listening us. Thank you.
