Lecture – 40
Charpit's Method- I

Hello friends, welcome to this lecture and in this lecture, we will continue our study of compatible system and if you recall in a previous lecture, we have discussed the definition of compatibility as follows.

(Refer Slide Time: 00:39)

$\checkmark [f, g] = 0 \Rightarrow \frac{\partial(f, g)}{\partial(x, y)} + p \frac{\partial(f, g)}{\partial(z, p)} + q \frac{\partial(f, g)}{\partial(z, q)} = 0$

$\checkmark f(x, y, z, p, q) = 0$
 $\checkmark g(x, y, z, p, q) = 0$

$\frac{\partial(f, g)}{\partial(p, q)} \neq 0, \quad \frac{dz = p dx + q dy}{z = z(x, y)}$

Here, we say that $f(x, y, z, p, q) = 0$ and $g(x, y, z, p, q) = 0$ are said to be compatible if every solution of first equation is a solution of second equation and vice versa and then we have considered a method of finding at least one solution in common that is you; let us assume that Jacobian of f, g with respect to p, q is nonzero and corresponding $dz = p dx + q dy$ is integrable to obtain; give a solution like $z = z(x, y)$.

And so, in fact this procedure is to find out the common solution they have, so this method is equally applicable in any 2 equations where they have one solution in common, so based on this in some book or in some literature, they define compatibility in this manner that f and g are compatible to each other, if they have at least one solution in common and the procedure listed here that Jacobian is nonzero.

And the $dz = pdx + qdy$ is integrable is the method to find out that common solution, so then we also discussed the procedure that in place of writing these 2 condition separately, can we simply look at the equation number ; equation f and g to say that whether they are that by f and g can be find out once common solution and that we have obtained in the following thing that if bracket fg is $= 0$ that is Jacobian of fg with respect to $xp + p$ times Jacobian of fg with respect to $zp +$ Jacobian of fg with respect to $yq + q$ Jacobian of fg with respect to zq .

If this quantity is $= 0$, then we are able to find out one common solution of f and g here, so here I am not saying that compatibility means what but I am giving you both the condition that in many of books, you say compatibility means every solution common and in some book, you will find out that they have at least one solution is common but this definition may be say, given in different, different but they give this procedure to find out that one common solution.

So, I am assuming that we are using this condition that bracket of fg is $= 0$ to say that they have at least one solution in common and the procedure that $dz = pdx + qdy$ is integrable to find out that common solution is that okay. So, now proceed further and see what we can further achieve.

(Refer Slide Time: 03:52)

Remark 2

The necessary and sufficient condition for two independent PDEs of the first order (1) and (2) to have an integral in common is $J = \partial(f, g) / \partial(p, q) \neq 0$ and $[f, g] = 0$.

Remark 3

Given a PDE of first order $f(x, y, z, p, q) = 0$ has integral in common with the equation $g(x, y, z, p, q) = 0$ if the function $g(x, y, z, p, q)$ satisfies the following homogeneous linear PDE of the first order:

$$\left(-\frac{\partial f}{\partial p}\right)\frac{\partial g}{\partial x} + \left(-\frac{\partial f}{\partial q}\right)\frac{\partial g}{\partial y} + \left(-p\frac{\partial f}{\partial p} - q\frac{\partial f}{\partial q}\right)\frac{\partial g}{\partial z} + \left(p\frac{\partial f}{\partial z} + \frac{\partial f}{\partial x}\right)\frac{\partial g}{\partial p} + \left(q\frac{\partial f}{\partial z} + \frac{\partial f}{\partial y}\right)\frac{\partial g}{\partial q} = 0$$

So, here the necessary and sufficient condition for 2 independent PDE of the first order 1 and 2 to how an integral in common is this that Jacobian is nonzero and the bracket is 0 and if you look

at the bracket fg is $= 0$ is already involving this condition that Jacobian is nonzero and basically this is an integrability condition that $dz = p dx + q dy$ is integrable to this, so basically I will assume that this is nothing but an integrability condition.

But in many books you will find this condition as a compatibility condition, so whatever you; if you look at compatibility means they have one solution in common, I agree that bracket $fg = 0$ is a compatibility condition but I will assume this bracket $fg = 0$ is a method to find out the common solution that f and g are having. So, next remark is that given a PDE of first order $f x y z p q = 0$ has integral in common with the equation $g x y z p q = 0$.

If the function $g x y z p q$ satisfy the following homogeneous linear PDE of the first order that is $-fp gx + -fq gy - p fp - q fq * dz + p of z + fx gp + q fz + fy * gq$ is $= 0$ and in fact, this is nothing but if you have; we say that here f and g have one solution common means, the bracket fg is $= 0$ and when you expand this, then we can arrange like this.

(Refer Slide Time: 05:40)

$$\begin{aligned}
 \checkmark [f, g] = 0 &\Rightarrow \checkmark \left[\frac{\partial(f, g)}{\partial(x, y)} + p \frac{\partial^2(f, g)}{\partial(x, y)^2} + \frac{\partial(f, g)}{\partial(y, z)} + q \frac{\partial^2(f, g)}{\partial(y, z)^2} \right] = 0 \\
 fg = 0 &\Rightarrow g_x dx + f_y dy + g_z dz + g_p dp + g_q dq = 0 \\
 g_x dx + f_y dy + g_z dz + g_p dp + g_q dq &= 0 \\
 \checkmark \frac{\partial(f, g)}{\partial(x, y)} + \frac{\partial(f, g)}{\partial(y, z)} + \frac{\partial(f, g)}{\partial(p, q)} &= 0 \\
 -g(x, y, z, p, q) &= 0 \\
 \checkmark \left[\frac{\partial(f, g)}{\partial(p, q)} \neq 0 \right] & \left| \begin{array}{l} dz = p dx + q dy \\ z = z(x, y) \end{array} \right.
 \end{aligned}$$

Here, we can write it that dg is $= 0$ or we can say that $g_x dx + g_y dy + g_z dz + g_p dp + g_q dq = 0$, so when you expand this, then you can write g_x into this $+ g_y * this + g_z * and g_p$ and this is fresh and you can get it from this in fact, if you look at the coefficient of g_x will be what? Coefficient of g_x will be fp ; $-fp$, so that is what we have written, so this condition that g satisfy this homogeneous linear PDE of the first order, we can obtain by expanding this bracket fg is $= 0$.

And we can get that g will satisfy the following homogeneous linear PDE of the first order and this is very, very important remark and we will use this remark in Charpit method to find out the complete integral of a first order nonlinear first order PDE, so let us move ahead and look at the remark 4.

(Refer Slide Time: 06:50)

Remark 4

If the two functions f and g are independent on z , then the condition that f and g are compatible to each other i.e. $[f, g] = 0$ is simplified. The following expression, where ξ and η are any functions of x, y, p, q :

$$\checkmark (\xi, \eta) = \frac{\partial \xi}{\partial p} \frac{\partial \eta}{\partial x} - \frac{\partial \eta}{\partial p} \frac{\partial \xi}{\partial x} + \frac{\partial \xi}{\partial q} \frac{\partial \eta}{\partial y} - \frac{\partial \eta}{\partial q} \frac{\partial \xi}{\partial y} \checkmark$$

is called the parenthesis (ξ, η) . The conditions that the equations $f(x, y, p, q) = 0$ and $g(x, y, p, q) = 0$ be compatible is that the equation $(f, g) = 0$ is true.

And this remark 4 says that if the 2 function f and g are independent of z , it means that they are writing only f of x, y, p, q and g of x, y, p, q , then the expression that bracket $fg = 0$ is simplified and we can say that that can be written as only this and that parenthesis fg is $= 0$, where parenthesis fg is defined like this, parenthesis of ξ, η is $\frac{\partial \xi}{\partial p} \frac{\partial \eta}{\partial x} - \frac{\partial \eta}{\partial p} \frac{\partial \xi}{\partial x} + \frac{\partial \xi}{\partial q} \frac{\partial \eta}{\partial y} - \frac{\partial \eta}{\partial q} \frac{\partial \xi}{\partial y}$.

So, it means that here f and g both are independent of z , then we simply look at the parenthesis $fg = 0$, where parenthesis ξ, η is given by this expression, so it is just a case of the bracket $fg = 0$, when f and g are not involving any z . Now, let us consider one example based on this compatibility procedure.

(Refer Slide Time: 08:04)

Example 4

Show that the equation $z = px + qy$ is compatible with any equation $f(x, y, z, p, q) = 0$ that is homogeneous in $x, y,$ and z . Solve the simultaneous equations $z = px + qy$ and $2xy(p^2 + q^2) = z(y p + x q)$.

solution. Consider the pde $f(x, y, z, p, q)$

$$f(\alpha x, \alpha y, \alpha z, \alpha p, \alpha q) = \alpha^n f(x, y, z, p, q)$$

$$x k_x + y k_y + z k_z = n f$$

and denote

$$f(x, y, z, p, q) = 0$$

$$g(x, y, z, p, q) := px + qy - z$$

Now to show that f and g are compatible we have to show that

$$[f, g] = 0. \quad \checkmark$$

Here

$$[f, g] = \frac{\partial(f, g)}{\partial(x, p)} + p \frac{\partial(f, g)}{\partial(z, p)} + \frac{\partial(f, g)}{\partial(y, q)} + q \frac{\partial(f, g)}{\partial(z, q)}$$

So, here we say that show that the equations $z = px + qy$ is compatible with any equation f of $x, y, z, p, q = 0$ that is homogeneous in x, y and z and once we show that they are compatible to each other, we try to find out the 2 equations, $z = px + qy$ and $2xy p^2 + q^2 = z y p + x q$ and we want to find out the common solution they have. So, here I just want to note that the homogeneous equation in x, y, z is we say that any equations say, f of x, y, z, p, q , we are talking about.

We say that f of x, y, z, p, q is homogeneous in terms of x, y and z , if we replace x, y, z by $\alpha x, \alpha y, \alpha z$, then we will should get $\alpha^n f$ of x, y, z, p, q and in this case we say that your equation f is homogeneous in terms of x, y, z of the degree n , where n is the power of α here. So, here by this we can find out the degree and they also have very important relations that is if f is homogeneous in x, y and z , then we have this relation that f of $x, y, z, p, q = n$ times f .

Here, n is the degree of the; n is the power of this α , so we call this as degree of the homogeneity. So, here with this information, now let us see that if f satisfy this condition, then it is compatible with $z = px + qy$, so now let us assume this equation f of $x, y, z, p, q = 0$ and another equation, g of x, y, z, p, q as $px + qy - z$ and we want to show that they are compatible to each other, so let us look at the bracket fg and we try to show that this bracket fg is $= 0$.

Now, look at the bracket fg here, it is what? Dou of fg upon dou fg dou xp + p times Jacobian of fg with respect to zp + Jacobian of fg with respect to yq + q times Jacobian of fg with respect to zq.

(Refer Slide Time: 10:39)

$$\begin{aligned}
 [f, g] &= \begin{vmatrix} f_x & f_p \\ g_x & g_p \end{vmatrix} + p \begin{vmatrix} f_z & f_p \\ g_z & g_p \end{vmatrix} + \begin{vmatrix} f_y & f_q \\ g_y & g_q \end{vmatrix} + q \begin{vmatrix} f_z & f_q \\ g_z & g_q \end{vmatrix} = px + qy - z \\
 \text{or} \\
 [f, g] &= \begin{vmatrix} f_x & f_p \\ p & x \end{vmatrix} + p \begin{vmatrix} f_z & f_p \\ -1 & x \end{vmatrix} + \begin{vmatrix} f_y & f_q \\ q & y \end{vmatrix} + q \begin{vmatrix} f_z & f_q \\ -1 & y \end{vmatrix} \\
 &= xf_x - pf_p + p(xf_z + f_p) + yf_y - qf_q + q(yf_z + f_q) \\
 &= xf_x + yf_y + px f_z + qy f_z \\
 &= xf_x + yf_y + (px + qy) f_z = x f_x + y f_y + z f_z = \nabla f \cdot \nabla g = n \cdot \nabla f \\
 &= \nabla f \cdot \nabla g = 0
 \end{aligned}$$

Now, let us simplify this further, so I can write, Jacobian of fg with respect to xp as this fx fp gp + p times fz fp gz gp fy fp gy gq + q times fz fq gz gq, now, here we already know that g x y z p q is = px + qy - z, let me see whether it is correct, it is what? Px + qy - z, okay, so this is the bracket fg. Now, let us simplify, since we do not have any expression for f, we simply know the properties of f that it is homogeneous in terms of x y and z, that is all, nothing is given neither the degree is given nor the exact formulation is given.

So, here let us use this expression for g only, so let us calculate g of x; g of x is = p, g of y is = q, q of p = x, g of q = y and g of z = -1, so using this let us again calculate bracket of fg, so fx fp now in place of gx let us; gx is p here, so let me write it here, gp is x here, let me write it x here + p times fz fp gz is -1 that is given here and gp is x, which is already calculated here + fy fy, now gy is what?

Gy is q here and gq is y here, let me write it here + q fz fq and gz; gz is -1 and gq is y, so now let us simplify this, it is what; x fx, so this is x fx - p fp, we have simplified this + p times, it is what; x fz + fp, so this is the expression plus, here we write y fy - q fq + q times y fz + fq, so we

have simply written down. Now, we can simply say that $x^2 + y^2 = z^2$, let us write it like this; $x^2 + y^2 = z^2$.

Now, here you can see that this px , here this will be cancelled out from this and similarly, qy will be cancelled out like this, so what we will have is $px^2 + qy^2 = z^2$, so this term is left and this term is left, so we are writing here, $x^2 + y^2 + px^2 + qy^2 = z^2$, now if you look at, if we take out this z^2 common, then we have $px + qy$ and we already know the value of $px + qy$ in terms of z and we can write this as $x^2 + y^2 + z^2 = z^2$.

And we know that if f is homogeneous in terms of x, y and z , then this expression is nothing but n times f , now we already have that the expression f of $x, y, z = px + qy$, this value is coming out to be 0 , so n is 0 , so we have this value is 0 . So, what we have shown here, we have calculated the bracket fg and we have say using the property of homogeneity, this value is coming out to be 0 . So, it means that any equation which is homogeneous in terms of x, y, z .

And $px + qy = z^2$ are compatible to each other, now once they are compatible to each other then we can find out the common solution and to find out the common solution, we need to know what are the value of p and q , so here for that we have simply taking expression for f of x, y, z that is $2xy + p^2 + q^2 = z^2$. Now, here if you look at this is homogeneous equation in terms of x, y and z , how we can check?

(Refer Slide Time: 14:33)

Example 4

Show that the equation $z = px + qy$ is compatible with any equation $f(x, y, z, p, q) = 0$ that is homogeneous in $x, y,$ and z . Solve the simultaneous equations $z = px + qy$ and $2xy(p^2 + q^2) = z(yq + xp)$.

solution. Consider the pde $f(x, y, z, p, q)$

$$f(ax, ay, az, p, q) = \lambda f(x, y, z, p, q) = 0$$

and denote

$$g(x, y, z, p, q) := px + qy - z$$

Now to show that f and g are compatible we have to show that

$$[f, g] = 0. \quad \checkmark$$

Here

$$[f, g] = \frac{\partial(f, g)}{\partial(x, p)} + p \frac{\partial(f, g)}{\partial(z, p)} + \frac{\partial(f, g)}{\partial(y, q)} + q \frac{\partial(f, g)}{\partial(z, q)}$$

Handwritten notes:
 $\lambda f_x + \lambda y f_y + \lambda z f_z = \lambda f$
 $f(\lambda x, \lambda y, \lambda z, p, q) = \lambda^2 f(x, y, z, p, q)$
 $= \lambda^2 [2xy(p^2 + q^2)]$
 $= \lambda^2 f(x, y, z, p, q)$

You simply write this as f of $x, y, z, p, q =$ let me write it here $2xy p^2 + q^2 - z y p + x q$, now what you simply write in place of x , let us write $\lambda x, \lambda y, \lambda z, p, q$ and if you simplify what you will get? Here, you will get a λ^2 in common from 1st term $2xy p^2 + q^2$ and $-z y p + x q$; here if you write $\lambda z, \lambda y$, so again you can take out λ^2 and what you will get?

$z y p +$ here also from this one λ and from this one λ , so λ^2 you can take it out, so $x q$, right, so when you simplify this, then it is λ^2 times f of x, y, z, p, q , so we can say that this is a homogeneous equation in terms of x, y, z with degree 2, right. Now, you want to show that since we have already proved that if f is homogeneous with respect to x, y, z and $z = px + qy$, then they are compatible to each other.

(Refer Slide Time: 16:02)

$$z = px + qy$$

From the first equation, we have $q = \frac{(z-px)}{y}$, substituting into the second equation gives

$$p = \frac{z}{2x} \left(p = \frac{xz}{x^2 + y^2} \right) \quad f = \frac{z - px}{y}$$

Making use of the first value of p gives $q = \frac{z}{2y}$. Now from $z = px + qy$, we have

$$dz = p dx + q dy \quad dz = \frac{z}{2x} dx + \frac{z}{2y} dy$$

and this gives $\frac{2}{z} dz = \frac{1}{x} dx + \frac{1}{y} dy$ which implies that

$$z^2 = C_1 xy.$$

$$\frac{2 dz}{z} = \frac{dx}{x} + \frac{dy}{y}$$

$$\Rightarrow 2 \ln z = \ln x + \ln y + \ln C$$

$$\boxed{z^2 = C xy}$$

Now, we want to show that let us take a particular form of that is this and $z = px + qy$ compatible means we can find out one common solution, so let us try to find out one common solution here. So, here we have $z = px + qy$.

(Refer Slide Time: 16:10)

$$z = px + qy$$

$$2xy(p^2 + q^2) = z(yq + px)$$

$$q = \frac{z - px}{y}$$

$$\frac{dz = p dx + q dy}{z = z(x, y)}$$

$$2xy \left(p^2 + \frac{(z - px)^2}{y^2} \right) = z \left(yq + \frac{(z - px)}{y} \right)$$

$$\frac{2xy \left(p^2 y^2 + (z - px)^2 \right)}{y^2} = \frac{z(y^2 q + z - px)}{y}$$

$$2x \left(p^2 y^2 + z^2 + p^2 x^2 - 2zpx \right) = z(y^2 q + z - px)$$

$$\checkmark \quad 2x \left(p^2 (y^2 + x^2) \right) - p(2x \times 2z x - z y^2 + z x) = -2x z^2 + z^2$$

And let me do it in a separate page, so here we have $z = px + qy$ and second equation is what? $2xy$, let me use here, it is $2xy p^2 + q^2 = z(yq + px)$, I hope I have written correctly; $yp + xq$, is that okay. Now, we already proved that it is a compatible to each other and we need to find out the common solution, it means that $dz = p dx + q dy$ is integrable to each other. Now, we already know that since bracket fg is 0.

So, it means that this has to be integrable because that is a condition we already proved, so it means that what we need to do here; we need to find out p and q from these 2 equation and put it here and then use our experience to solve this equation and to get this equation as z of x y and maybe one integration constant will also appear, so we can get that it is a one parameter family of solution.

So, now let us solve this, so for this, you simplify first equation as $z - px$ upon y , so we simply write down the value of q in terms of z p and x and y and put it in a second equation, so let us say $2xy p^2 + q^2$ is $z - px$ whole square $y^2 = z^2 y^2 + q^2$ is $z - px$ upon y here, so let me simple this as $z y^2 p^2 + z - px$ and here, we have y here. Now, here again we can write $2xy$, it is $p^2 y^2 + z - px$ whole square and we have y^2 .

Now, we can see y cancel and y , here y cancel, so here we can simplify further, we have $2x$, now inside it is $p^2 y^2 + z^2 + p^2 x^2 - 2z px = zy^2 p^2 + z - px$, it is given by this. Now, let us calculate the coefficient of p^2 here, so p^2 coefficient will be what? Here, it is what and to get $2x$ also common, so here, what you will get; here we will get y^2 and here we have x^2 , is there any other term?

No, we do not have any term, now let us calculate the coefficient of p here, so let me write it here, $-p$; what you will get here; $2x$ is here and here $2zx$ here, so let me write it, $2x * 2zx$, so that is what we have obtained here and here, if we look at the coefficient here; coefficient here is what? $-zy^2$ and $+zx$.

And the remaining is just a constant value, so which we can write it here as; what you will get? $2z^2$ is here, so I can write $-2x z^2$ and here I will get $+z^2$, so here we can get a expression for quadratic equation terms of p^2 and we can simplify for p using the theory of quadratic equation and you can get the value of p by solving this quadratic equation and we have equation as $p = z/2x$ and $p = xz/x^2 + y^2$.

I am leaving it to you, I in fact we have obtained a quadratic equation and then we can solve for p and you will have 2 values of p out of this, so I am saying that let us do this work and we have

obtained and we say that $p = z/2x$ is one value of p and another value is $p = xz$ upon $x^2 + y^2$. Now, once we have 2 values of p , then of course you will have 2 values of q as well, so let us solve for q .

Let us take the first value as $xz/2x$ then $q = z - px$; px is going to be $z/2$ divided by y , so it means q is going to be $z/2y$, so it means that we have now values of p and q , then look at your equation, $dz = pdx = qdy$, so let us say that $dz = pdx + qdy$ is here, then you simply write it dz and p is what? P is $z/2x dx$ and q is what? Q is your $z/2y dy$, so $z/2y dy$ and if you simplify this, it is what; dz/z in fact, you can take 2 here, then it is $dx/x + dy/y$ here.

And here, if you simplify this is what? This is; you can simplify you can write it $2\ln z = \ln x + \ln y + \ln c$, so we can write $z^2 = c \times xy$, I am using c_1 here, so you can write the one solution is $z^2 = c xy$, so once we have one value of p , you have another value for q , which we can obtain using the equation as well as this value and we have a common solution $z^2 = c xy$.

(Refer Slide Time: 22:11)

Similarly, using the second value for p , gives $q = \frac{yz}{(x^2+y^2)}$ and this further implies:

$$\checkmark dz = \frac{yzdy}{(x^2+y^2)} + \frac{xzdx}{(x^2+y^2)}$$

On solving, we get:

$$dz = \frac{yzdy}{(x^2+y^2)} + \frac{xzdx}{(x^2+y^2)} \Rightarrow \frac{2dz}{z} = \frac{2(xdx + ydy)}{(x^2+y^2)}$$

$$\Rightarrow z^2 = C_2(x^2+y^2) \quad d(z^2) = d(x^2+y^2)$$

Handwritten notes:
 $p = \frac{xz}{x^2+y^2}$
 $q = \frac{z-px}{y} = z - \frac{x^2z}{x^2+y^2} = \frac{z(x^2+y^2 - x^2)}{x^2+y^2} = \frac{zy}{x^2+y^2}$

Now, we if we use the other value that is xz upon $x^2 + y^2$ as p , then you can write p as xz upon $x^2 + y^2$ and q is what; q is $z - px$ upon y ; $z - px$ upon y here, so let me write it here, $z - px$, so I can write it $x^2 z$ upon $x^2 + y^2$ divided by y and if you

simplify $zx^2 + zy^2 - x^2z$ divided by y times $x^2 + y^2$, right. So, $zx^2 + zy^2$ is cancel out here, so we have zy , y is also cancel out.

So, we have zy divided; sorry sorry, so here we will get zy upon $x^2 + y^2$, so that is a value of q , so q is zy upon $x^2 + y^2$, which we have written here, the q is zy upon $x^2 + y^2$. So, we have q , we have p , now let us simplify $dz = p$ means, p here xz upon $x^2 + y^2$ $dx + qdy$, so $yz dy$ upon $x^2 + y^2$. Now, let us; since we already know that it is integrable, the only thing is we have to make it in a form such that exact integration is possible.

So, here you can take out that z here, so we can write this as, you can take out z here, we can write $dz = yz dy$ upon $x^2 + y^2 + xz dx$ upon $x^2 + y^2$, then we can simply write, you can take that common and you can write dz upon z and then you multiply by 2, so it is $2x dx + y dy$ divided by $x^2 + y^2$, so this is what it is the derivative of z^2 and if you look at this is what derivative of $x^2 + y^2$.

So, we can simply say that you can write a $z^2 = \text{some constant } c \times x^2 + y^2$, so we can say that this is another common solution they have, if we use a value p as xz upon $x^2 + y^2$, so that is what we have achieved here. So, what we have shown here; we have shown here that any equation, which is homogeneous in x , y , and z is compatible with $z = px + qy$ and then we have taken a particular form of $f(x, y, z, p, q)$ that is $2xy p^2 + q^2 = z yp + q yp + xq$.

And we have found out the common solution they have and in this case, they have 2 common solutions which we have obtained by $z^2 = c_1 xy$ and $z^2 = c_2 \times x^2 + y^2$ square here.

(Refer Slide Time: 25:08)

Charpit Method

The general PDE of order one is denoted by

$$f(x, y, z, p, q) = 0 \quad (24)$$

The fundamental idea in this method is the introduction of second PDE of order one

$$g(x, y, z, p, q) = a \quad (25)$$

which contains an arbitrary constant a and satisfying the following conditions

(i) Equations (24) and (25) can be solved to give $p = p(x, y, z, a)$ and $q = q(x, y, z, a)$

(ii) The equation

$$dz = p(x, y, z, a)dx + q(x, y, z, a)dy \quad (26)$$

is integrable to obtain the two-parameter solution $F(x, y, z, p, a, b) = 0$.

So, now based on this, now let us define an important method that is Charpit method, so what we try to do here, our aim is to find out the complete solution of a first order non-linear PDE that is $f(x, y, z, p, q) = 0$, so here we want to find out a complete solution of this equation and how we obtain it following that using the concept of compatibility, so it means that if we are able to find out another say, PDE that is say, $g(x, y, z, p, q) = a$.

Here, a is some kind of parameter, so we say that if the fundamental idea in this method is the introduction of second PDE of order one that is $g(x, y, z, p, q) = a$, which contains an arbitrary constant a and satisfying the following condition, following condition is that, we can solve these 2 equations for p and q and of course since the equation of g which involve 1 parameter a , so p and q will also involve that parameter a .

And then once we have the value of p and q , then $dz = p(x, y, z, a)dx + q(x, y, z, a)dy$, a is integrable exactly, so when we find out the solution, then we have one parameter and we say that our solution is given as $f(x, y, z, p, x, y, z, a, b) = 0$ here and this is given as 2 parameter family of solution and we say that this solution as complete solution.

Charpit Method

Remark 5

The fundamental idea in Charpit's method is to determine an equation $g(x, y, z, p, q) = a$, containing an arbitrary constant a , such that equations (24) and (25) are compatible and can be solved to give explicit expressions for p, q in terms of x, y, z and the arbitrary constant a , that is $p = \phi(x, y, z, a)$, $q = \psi(x, y, z, a)$. The condition of compatibility requires that equation (26) is integrable.

$$dz = p dx + q dy$$

Remark 6

The main problem in Charpit's method is the determination of the second equation $g(x, y, z, p, q) = a$ with the property of compatibility with $f(x, y, z, p, q) = 0$. We shall show that this requirement leads to a set of simultaneous differential equations, from which g can be obtained.

So, here let me here the fundamental idea in charpit method is to determine an equation $g(x, y, z, p, q) = a$, so here, what we say that our main problem is how to find out differential equation; 2nd differential equation which has the following property that by which we can find out the expression for p and q and that the $dz = p dx + q dy$ is integrable and here it means that the another equation we need to find out that is $g(x, y, z, p, q) = a$ containing an arbitrary constant a , such that equation 24 and 25 are compatible to each other.

And can be solved to give explicit expression for p, q in terms of x, y, z and the arbitrary constant a that is $p = \phi(x, y, z, a)$ and $q = \psi(x, y, z, a)$ and the condition of compatible require that equation 26 is integrable that is $dz = p dx + q dy$ is integrable. So, idea is; are the problem is how to find out this one parameter equation of PDE, so that is the problem. So, the main problem in Charpit method is the determination of the second equation $g(x, y, z, p, q) = a$ having the property that it is compatible with $f(x, y, z, p, q) = 0$.

And we will; so that the g and f are compatible to each other will give you an idea how to find out this equation g and this is quite obvious if you remembered one of the remarks that g is compatible with f , if g satisfy certain homogeneous partial differential equation.

(Refer Slide Time: 28:58)

When such a given function g satisfying the above two conditions has been found, the solution of equation (26) containing two arbitrary constants will be a solution of equation (24). The condition (i) will be satisfied if $J = \frac{\partial(f,g)}{\partial(p,q)} \neq 0$. Assume that equation $[f, g] = 0$ is satisfied and equation (26) exists.

$$[f, g] = \begin{vmatrix} f_x & f_p \\ g_x & g_p \end{vmatrix} + p \begin{vmatrix} f_z & f_p \\ g_z & g_p \end{vmatrix} + \begin{vmatrix} f_y & f_q \\ g_y & g_q \end{vmatrix} + q \begin{vmatrix} f_z & f_q \\ g_z & g_q \end{vmatrix} = 0; \text{ or } \quad (27)$$

$$(-f_p)g_x + (-f_q)g_y + (-pf_p - qf_q)g_z + (pf_z + f_x)g_p + (qf_z + f_y)g_q = 0 \quad (28)$$

Now compare this with $dg = 0$, i.e.

$$g_x dx + g_y dy + g_z dz + g_p dp + g_q dq = 0$$

So, when such a given function f satisfying the above 2 condition has been found, it means that if we find out g such that g and f are compatible to each other and g is already having one parameter, then we can say that our solution of equation 26 is contained 2 arbitrary constants will be a solution of equation $f \times y \ z = a$ and the condition 1 will be what? Condition 1 means that f and g can be solvable in terms of p and q is equivalent that Jacobian fg with respect to pq is nonzero.

And that f and g are having one solution in common means $dz = pdx + qdy$ is integrable is simply say that we can say that our bracket $f g$ has to be 0, the value of fg has to be 0, now look at the bracket fg , it is $f_x f_p g_x g_p + p$ times determinant of $f_z f_p g_z g_p$ and so on, so this expression has to be = 0 and if we simplify I can write this expression that minuses $-f_p g_x + -f_q g_y - pf_p - q f_q g_z + pf_z + f_x g_p + qf_z + f_y g_q = 0$.

So here, we simplify this bracket $fg = 0$ in a way such that we write in in terms of coefficient of g_x, g_y, g_z, g_p and g_q and now let us compare this equation number 28 with the following thing that $dz = 0$, here you have $g \times y \ z \ p \ q = a$, so if you find out the total derivative, then total derivative dg is coming to be 0 and when we expand it, we have the following thing that $g_x dx + g_y dy + g_z dz + g_p dp + g_q dq = 0$.

(Refer Slide Time: 31:12)

$$\frac{dx}{\frac{-\partial f}{\partial p}} = \frac{dy}{\frac{-\partial f}{\partial q}} = \frac{dz}{\frac{-p\partial f}{\partial p} - q\frac{\partial f}{\partial q}} = \frac{dp}{\frac{\partial f}{\partial x} + p\left(\frac{\partial f}{\partial z}\right)} = \frac{dq}{\frac{\partial f}{\partial y} + q\left(\frac{\partial f}{\partial z}\right)} \quad (29)$$

Equation (29) is known as Charpit's subsidiary equations which can also be written in the form

$$\frac{dx}{f_p} = \frac{dy}{f_q} = \frac{dz}{pf_p + qf_q} = \frac{dp}{-f_x - pf_z} = \frac{dq}{-f_y - qf_z} = dt \quad (30)$$

So, it means that if g is given like this then it must satisfy the equation number 28 and this equation and if we compare these 2 equations, then we have the following thing that dx upon $-fp$, if you look at compare here, dx upon $-fp$, dy upon $-fq$, dz upon $-pfp - qfq$, dp upon $pfz + fx$ and dq upon this quantity and we have a set of equations which is known as equation number 29 and we call this as Charpit subsidiary equation.

So, here managing this $-$ sign out and we have dx upon $fp + dy$ upon $fq =$; sorry, dx upon $fp = dy$ upon $fq = dz$ upon $pfp + qfq = dp$ upon $-fx - pfz = dq$ upon $-fy - qfz$ and these equations are known as Charpit subsidiary equation. Now, if you recall the Cauchy method of characteristics then if you equate this value as some dt , where t is some parametric; parameter, then it is; the equation which you have a obtained in Cauchy method characteristic, an equation what we have obtain right now as same.

The only thing is that they been have some initial condition here, we do not have any initial condition, so that is only difference we have now, so it means that when we solve this equation, so then we will get an expression for $g(x, y, z, p, q)$, here what we have seen that here, dx, dy, dz, dp basically, they will characterise the surface $g(x, y, z, p, q)$; $g(x, y, z) = a$; $g(x, y, z, p, q) = a$, so that is our idea how to solve this equation number 30 to find out the expression $g(x, y, z, p, q)$.

General strategy for Charpit method

- (i) Transfer all terms of the given equation to left-hand side and denote all expression by f .
- (ii) Write the Charpit auxiliary equation (30).
- (iii) Using the value of f in first step, calculate the value of f_x, f_y, f_z, f_p and f_q in step (ii) and put these in (30).
- (iv) Select two proper fractions so that the resulting integral may come out to be the simplest relation involving at least one of p and q .
- (v) The simplest relation of step (iv) is solved along with the given equation to determine p and q . By putting these values of p and q in $dz = pdx + qdy$ which on integration gives the required complete integral of the given equation.

When we solve this, we try to do some kind of integration and by which we have 1 parameter involved, so what we try to do here, we discuss the general strategy for Charpit method, so here transfer all terms of the given equation to left hand side and denote all expression for f , so here whatever equation we have, you just transfer everything into one side and denote that expression by f and write the Charpit auxiliary equation 30.

And using the value of f in first step calculated the value of f_x, f_y, f_z, f_p, f_q and put in equation number 30 and then this is very important step that select 2 proper fraction, so that the resulting integral may come out to be the simplest relation involving at least one of p and q , so here out of these set, they are 1, 2, 3, 4, 5 you choose at least 2, so that we can get expression; a simpler expression for p and q , right, p or q .

So, once we have an expression for p and q , use the equation, the simplest relation of step 4 is solved along the given equation to determine p and q , given equation means, f of $x y z p q = 0$, so once we have p , then of course since they have one solution in common then that must satisfy this given equation that is f of $x y z p q = 0$, so by this you find out the expression for q , so in this way we are able to find out both p and q .

And once we have the values of p and q put in $dz = pdx + qdy$ and solved for your integral and in this way we can find out the integral and that is the required complete integral of the equation, f

of $x y z p q = 0$ and this is the method, which we follow and we find the complete integral and here we will stop and in next lecture will apply this strategy of Charpit method to find out complete integral, so thank you for listening us, thank you.
