**Lecture - 45**  
**Classification and Characteristic Curves of Second Order PDEs**

Welcome to my lecture on Classification and Characteristic Curves of Second Order PDEs. So we will classify the second order PDE according to the sign of discriminant  $S^2 - 4RT$ . So, let us see how we define how we classify the second order PDE.

**(Refer Slide Time: 00:52)**

The classification of second order PDE depends on the form of the leading part of the equation consisting of the second order terms.

The type of the second order PDE (1) at a point  $(x_0, y_0)$  depends on the sign of the discriminant defined as

$$\Delta(x_0, y_0) = \begin{vmatrix} S & 2R \\ 2T & S \end{vmatrix} = S^2(x_0, y_0) - 4R(x_0, y_0)T(x_0, y_0).$$

If  $\Delta(x_0, y_0) > 0$ , the equation is called hyperbolic;  $\Delta(x_0, y_0) = 0$ , the equation is parabolic and  $\Delta(x_0, y_0) < 0$ , the equation is elliptic.

Note that the given PDE may be of one type at a specific point and of another type at some other point.

The classification of second order PDE depends on the form of the leading part of the equation consisting of the second order terms. And this leading part is  $Rr + Ss + Tt$ . Because this is the only part which consist of second order terms. Remaining is  $fx + yz + pq = 0$ . No second order term is involved here. So this part is called the leading part so the classification of second order PDE depends on the form of this  $Rr + Ss + Tt$  which is known as the leading part.

Or the principal part of the second order PDE. Now the type of second order PDE at a point  $x_0, y_0$  depends on the sign of the discriminant. It is defined as  $\Delta$  at  $x_0, y_0 = S^2 - 4RT$  that is  $S^2 - 4RT$  at the point. So,  $\Delta$  we calculate the values of  $S, R$  and  $T$  at the point  $x_0$  and  $y_0$  and then determine  $S^2 - 4RT$  at the point  $x_0$  and  $y_0$ . If this  $S^2 - 4RT$  at  $x_0, y_0$  is  $> 0$  then the equation will be called hyperbolic.

And if this is  $\Delta = 0$  it is called parabolic and if this is  $\Delta < 0$  we called it elliptic. The given PDE may be one type at a specific point and of another type at some other point. So it may happen that at  $x_0, y_0$  it is of hyperbolic type and at another point  $x_1, y_1$  it is parabolic type or it is elliptic type. So, the given may be of one type at a specific point and of another point at some other point.

**(Refer Slide Time: 02:52)**

For example, the Tricomi equation

$$u_{xx} + xu_{yy} = 0$$

is hyperbolic in the left half plane  $x < 0$ ; parabolic for  $x = 0$  and elliptic in right half plane  $x > 0$ , since  $\Delta = -4x$ .

A PDE is called hyperbolic ( or parabolic or elliptic) in a region  $\Omega$ , if the PDE is hyperbolic ( or parabolic or elliptic) at each point of  $\Omega$ .

The terminology hyperbolic, parabolic and elliptic chosen to classify PDEs reflects the analogy between the form of the discriminant  $S^2 - 4RT$ , for PDEs and the form of the discriminant  $S^2 - 4RT$ , which classifies conic sections given by

$$Rx^2 + Sxy + Ty^2 + ux + vy + w = 0$$

For example, let us consider this Tricomi equation  $u_{xx} + xu_{yy} = 0$ . So, if you compare this with this standard form  $Rx^2 + Sxy + Ty^2 + f(x, y) + p = 0$ . Here  $u_{xx}$  the coefficient of  $u_{xx}$  is 1 so  $R = 1$  and  $S = 0$  and  $T = x$ . So,  $\Delta$  which is  $S^2 - 4RT$  the discriminant will be  $\Delta = 0 - 4(1)(x) = -4x$ . So,  $\Delta$  is  $-4x$  so now you can see at the point at for any value of  $x$  in the left half plane let us say this is your  $Ox$  axis  $y$  axis so this is your left half plane.

So,  $x < 0$  and in the right half plane okay  $x > 0$  So, in the left half plane that is here  $x < 0$  and when  $x < 0$   $\Delta$  is positive so  $\Delta$  is positive in this side okay parabolic when  $x = 0$  that means on the  $y$  axis, that is on the okay this Tricomi equation is parabolic on  $y$  axis hyperbolic in the left side of the plane left half plane and elliptic in the right half plane. Because in the right half plane  $x > 0$  and when  $x > 0$   $\Delta$  is  $< 0$  okay.

So, at different points in the  $xy$  plane the nature of the Partial differential Equation is different. A PDE is called hyperbolic or parabolic or elliptic in a region  $\omega$  of the  $xy$  plane if the PDE is hyperbolic or parabolic or elliptic at each point of  $\omega$ . The terminology hyperbolic, parabolic and elliptic chosen to classify PDEs reflects the analogy. Between the form of the discriminant  $S^2 - 4RT$  for the PDEs and the form of the discriminant  $S^2 - 4RT$ .

Which classifies the conic sections. You know that conic sections are given by the second-degree equation  $Rx^2 + Sxy + Ty^2 + ux + vy + w = 0$ . And we say that this conic section represents hyperbola if  $S^2 - 4RT > 0$  and it represents parabola if  $S^2 - 4RT = 0$  and it represents ellipse if  $S^2 - 4RT < 0$ . So, by analogy okay of the given PDE of second order the given PDE as hyperbolic, parabolic or elliptic according as  $S^2 - 4RT > 0$ ,  $= 0$  or  $< 0$ .

**(Refer Slide Time: 06:23)**

The above conic section represents a hyperbola, parabola or ellipse respectively according as  $S^2 - 4RT > 0$ ,  $= 0$  or  $< 0$ . There is no other significance to the terminology. The terms hyperbolic, parabolic and elliptic are simply three convenient names to classify PDEs.

The above conic section represents a hyperbola, parabola or ellipse respectively according as  $S^2 - 4RT > 0$ ,  $= 0$  or  $< 0$ . So, this is the region why we have called the given PDE of second order as hyperbolic parabolic and elliptic. The terms hyperbolic parabolic and elliptic are simply the 3 convenient names to classify PDEs. There is no other significance to this terminology.

**(Refer Slide Time: 06:55)**

Consider the second order PDE

$$Rr + Ss + Tt + f(x, y, z, p, q) = 0 \quad (1)$$

where R, S and T are functions of  $x$  and  $y$  only. The Cauchy's problem consists of the problem of determining the solution of (1) such that on a given space curve  $\Gamma$  it takes on prescribed values of  $z$  and  $\frac{\partial z}{\partial n}$ , where  $n$  is the distance measured along the normal to the curve.

Corresponding to (1), consider the  $\lambda$ -quadratic

$$R\lambda^2 + S\lambda + T = 0 \quad (2)$$

Consider the second order PDE  $Rr + Ss + Tt + f(x, y, z, p, q) = 0$  where R, S and T are functions of  $x$  and  $y$  only. The Cauchy's problem consists of the problem of determining the solution of second order PDE such that on a given space curve  $\Gamma$  it takes on prescribed values of  $z$  and the partial derivative of  $z$  where  $n$  is the distance measured along the normal to the curve corresponding to this equation (1) we know that  $\lambda$  quadratic is given by  $R\lambda^2 + S\lambda + T = 0$ .

**(Refer Slide Time: 07:33)**

If  $S^2 - 4RT > 0$  (i.e. if (1) is hyperbolic), then (2) has two distinct real roots

$\lambda_1$  and  $\lambda_2$ , say, so that we have two characteristic equations

$$\frac{dy}{dx} + \lambda_1(x, y) = 0 \quad \text{and} \quad \frac{dy}{dx} + \lambda_2(x, y) = 0.$$

Solving these equations, we get two families of characteristic curves or simply characteristics of the second order PDE (1).

If  $S^2 - 4RT > 0$  then just now we have seen the equation (1) is hyperbolic and in this case what happens is that the  $\lambda$  quadratic  $R\lambda^2 + S\lambda + T = 0$  has 2 distinct real roots say  $\lambda_1$  and  $\lambda_2$  and so that we have 2 characteristic equations  $dy/dx + \lambda_1(x, y) = 0$  and  $dy/dx + \lambda_2(x, y) = 0$ . Now Solving these characteristic equations, we get 2 families of

characteristic curves or we call them as simply characteristics of the second order PDE given by equation 1.

**(Refer Slide Time: 08:17)**

If  $S^2 - 4RT = 0$  (i.e. if (1) is parabolic), then (2) has two equal roots  $\lambda$  and  $\lambda$  so that we get only one characteristic equation

$$\frac{dy}{dx} + \lambda(x, y) = 0.$$

On solving this equation, we obtain only one family of characteristics.

Now if  $S^2 - 4RT < 0$  (i.e. if (1) is elliptic), then (2) has complex roots.

Hence, there are no real characteristics.

$$\frac{dy}{dx} + \lambda_1(x, y) = 0, \frac{dy}{dx} + \lambda_2(x, y) = 0$$

$\Rightarrow$  complex characteristics

If it so happens that  $S^2 - 4RT = 0$  then the equation 1 we defined as parabolic differential equation in that case what happens the lambda quadratic  $R\lambda^2 + S\lambda + T = 0$  has 2 equal roots okay let us call them as lambda and lambda so that we get only one characteristic equation  $dy/dx + \lambda xy = 0$ . When we solve this equation we get only one family of characteristics.

Now in the case  $S^2 - 4RT < 0$  the lambda quadratic  $R\lambda^2 + S\lambda + T = 0$  has 2 complex roots which are conjugate of each other then we notice that the characteristic equations are  $dy/dx + \lambda_1 xy = 0$   $dy/dx + \lambda_2 xy = 0$ . So, these are the characteristic equations in this case  $S^2 - 4RT < 0$   $\lambda_1 xy$  and  $\lambda_2 xy$  are complex roots so these 2 will give complex family of characteristics.

When we solve them we get complex characteristics. So, there are no real characteristics in this case.

**(Refer Slide Time: 09:50)**

**Example:** Let us consider the equation

$$y^2 r - x^2 t = 0.$$

$R = y^2, S = 0, T = -x^2$   
 $S^2 - 4RT = 0 - 4(y^2)(-x^2) = 4x^2y^2 > 0$  if  $x \neq 0$  and  $y \neq 0$   
 Hence the given PDE is elliptic everywhere except on the x-axis and the y-axis.

on x-axis,  $y=0$  hence  $S^2 - 4RT = 0$   
 the given PDE is parabolic.

on y-axis,  $x=0$  hence  $S^2 - 4RT = 0$   
 the given PDE is parabolic.

Consider the  $\lambda$  quadratic  $R\lambda^2 + S\lambda + T = 0$  then  $y^2\lambda^2 - x^2 = 0$   
 $\Rightarrow \lambda = \pm \frac{x}{y}$   
 $\lambda_1(x,y) = \frac{x}{y}, \lambda_2(x,y) = -\frac{x}{y}$

we have  $\frac{dy}{dx} + \lambda_1(x,y) = 0 \Rightarrow \frac{dy}{dx} - \frac{x}{y} = 0$   
 or  $y dy - x dx = 0$   
 $\frac{y^2}{2} - \frac{x^2}{2} = \frac{c_1}{2}$  or  $x^2 - y^2 = c_1^2$   
 Family of hyperbolas.

$\frac{dy}{dx} + \lambda_2(x,y) = 0 \Rightarrow \frac{dy}{dx} + \frac{x}{y} = 0$   
 $x dx + y dy = 0$   
 $\frac{x^2}{2} + \frac{y^2}{2} = \frac{c_2}{2}$   
 Family of circles.

Now let us consider the coefficient  $y^2 r - x^2 t = 0$  so comparing with the equation  $Rr + Ss + Tt + f(x, y, z, p, q) = 0$  you get  $R = y^2$ ,  $S = 0$ ,  $T = -x^2$ . So,  $S^2 - 4RT = 0$  so we get  $0 - 4(y^2)(-x^2) = 4x^2y^2 > 0$ . Okay. Hence the given PDE is elliptic everywhere okay except on the x-axis and the y-axis. So, it is  $> 0$  if  $x$  is not 0 and also  $y$  is not 0.

Okay, this means that, this is our x-axis and this is y-axis so on x-axis  $y = 0$  so,  $S^2 - 4RT = 0$ .

Okay this will come here so the given equation is PDE is, the given equation is parabolic. Okay same thing happens on y-axis on y-axis,  $x = 0$  hence  $S^2 - 4RT$  which is 4 times  $x^2 y^2$  so this is 0 so again the given PDE is parabolic. So on x-axis okay y-axis the given PDE is parabolic elsewhere.

Okay it is hyperbolic for all points in the xy-plane for all points in xy-plane other than those on the co-ordinate axis. The given PDE is hyperbolic. So, now let us consider the lambda quadratic which is  $R\lambda^2 + S\lambda + T = 0$ . Okay So, then since  $R = y^2$ ,  $S = 0$  so we have  $y^2\lambda^2 - x^2 = 0$ . So this gives you  $\lambda = \pm \frac{x}{y}$ . So, we have 2 characteristic equations.

We have  $\frac{dy}{dx} + \lambda_1(x,y) = 0$  which gives you taking  $\lambda_1(x,y) = \frac{x}{y}$ ,  $\lambda_2(x,y) = -\frac{x}{y}$  we get here  $\frac{dy}{dx} - \frac{x}{y} = 0$  or we can say  $y dy - x dx = 0$ . So, we get  $\frac{y^2}{2} - \frac{x^2}{2} = \frac{c_1}{2}$

we can take as  $c_1/2$  or you can say  $-c_1/2$  you take so  $Rx^2 - y^2 = \text{some constant } c_2$   
 okay now if you take other characteristic equation  $dy/dx + \lambda_2 x/y = 0$ . So, we have  $dy/dx$   
 here we have taken  $-x/y$  now we take  $\lambda_1 + x/y$  we have taken as  $-x/y$ .

So, this is  $x/y$  and  $\lambda_2 xy$  we can take as  $+x/y$ . So, this is  $+x/y = 0$  okay so  $x dx + y dy = 0$  gives  
 you  $x^2/2 + y^2/2 = \text{some constant } c_3/2$ . So, this gives you  $x^2 + y^2 = \text{some constant } c_3$ . So, now we get 2 characteristic family characteristic curves  
 one is given by  $x^2 - y^2 = c_2$  and one is given by  $x^2 + y^2 = c_3$  okay. So, this represents a family of hyperbolas and this represents family of circles.

So, the given PDE the characteristic curves are 2 families of, one is the family of hyperbolas and the other is the family of circles.

**(Refer Slide Time: 17:24)**

Hence, the characteristics are given by

$$x^2 + y^2 = c_1, \quad \text{and} \quad x^2 - y^2 = c_2$$

which are the required families of characteristics. Here these are the families of circles and hyperbolas respectively.

The characteristic of curves or characteristic are given are given by  $x^2 + y^2 = \text{some constant}$  and  $x^2 - y^2 = \text{some constant}$  which are the required families of characteristics. So these are the families of circles and hyperbolas.

**(Refer Slide Time: 17:41)**

**Example:** Let us consider the equation

$$4r + 5s + t + p + q - 2 = 0.$$

The  $\lambda$ -quadratic equation is  
 $R\lambda^2 + S\lambda + T = 0$   
 or  $4\lambda^2 + 5\lambda + 1 = 0$   
 $(4\lambda + 1)(\lambda + 1) = 0$   
 $\Rightarrow \lambda = -1, -\frac{1}{4}$

for  $\lambda = -\frac{1}{4}$ , we get  
 the other  $\frac{dy}{dx} + \lambda_2(x,y) = 0 \Rightarrow \frac{dy}{dx} - \frac{1}{4} = 0$   
 or  $4dy - dx = 0 \Rightarrow 4y - x = c_2$  (a family of straight lines)

Let us take  $\lambda(x,y) = -1$   
 then  $\frac{dy}{dx} + \lambda_1(x,y) = 0 \Rightarrow \frac{dy}{dx} - 1 = 0$   
 or  $dy - dx = 0 \Rightarrow y - x = c_1$  (a family of straight lines)

$R = 4, S = 5, T = 1$   
 $S^2 - 4RT = 25 - 16 = 9 > 0$   
 The given PDE is hyperbolic at all points of the  $xy$  plane

$R = 4, S = 5, T = 1$   
 $R - \gamma + S\lambda + T\lambda^2 + f(x,y,z,p,q) = 0$

Now, let us consider the equation  $4r + 5s + t + p + q - 2 = 0$ . So again let us compare, then what we have  $R = 4, S = 5, T = 1$ . So  $s^2 - 4RT$  here will be  $25 - 16$  that is  $9$  okay but it is strictly positive so the given equation is the given PDE is hyperbolic for all  $xy$  at all points of the  $xy$  plane. So, now let us write the lambda characteristic lambda quadratic equation  $R\lambda^2 + s\lambda + T = 0$ .

So in this case  $R$  is  $4$  so  $4\lambda^2 + 5\lambda + 1 = 0$  and its factors are  $4\lambda + 1 \cdot \lambda + 1$   $4\lambda^2 + \lambda + 1$ , yeah this gives you  $\lambda = -1$ , and  $-1/4$ . Let us take  $\lambda = -1$  okay the characteristic equations are  $dy/dx + \lambda_1(x,y) = 0$  so this gives you  $dy/dx - 1 = 0$  or  $dy - dx = 0$ .

So, we can find  $y - x = \text{some constant } c_1$  okay so this is one familiar of straight lines Now for  $\lambda = -1/4$  we get the other characteristic equation as  $dy/dx + \lambda_2(x,y) = 0$  which gives you  $dy/dx - 1/4 = 0$  or  $4dy - dx = 0$ . So, this implies  $4y - x = \text{some constant } c_2$  which is family of straight lines. So, this is a family of straight lines  $y - x/c_1$  is a family of straight lines  $4y - x = c_2$  is as also a family of straight lines So in this case the characteristics are 2 families of straight lines

**(Refer Slide Time: 21:47)**

Hence, the characteristics are given by

$$4y - x = c_1, \quad \text{and} \quad y - x = c_2.$$

Thus, we get two families of straight lines.

So, this is what we have.

(Refer Slide Time: 21:51)

**Example:** Find the D'Alembert's solution of the Cauchy's problem:

$$z_{xx} = \frac{1}{c^2} z_{tt}, \quad (c > 0)$$

satisfying  $z(x,0) = f(x)$  and  $z_t(x,0) = g(x)$

where  $f(x)$  and  $g(x)$  are given functions representing the initial displacement and the initial velocity, respectively.

*The given PDE is hyperbolic. Here  $z_{xx} - \frac{1}{c^2} z_{tt} = 0$ . Therefore  $R=1, S=0, T=-\frac{1}{c^2}$ .  
 $S^2 - 4RT = 0 - 4 \cdot 1 \cdot (-\frac{1}{c^2}) = \frac{4}{c^2} > 0$   
 The  $\lambda$ -quadratic is given by  $R\lambda^2 + S\lambda + T = 0$   
 or  $\lambda^2 - \frac{1}{c^2} = 0$  we have  $\lambda = \pm \frac{1}{c}$   
 Let  $\lambda_1(x,y) = \frac{1}{c}$   
 &  $\lambda_2(x,y) = -\frac{1}{c}$   
 then  $\frac{dy}{dx} + \lambda(x,y) = 0$  we have  $\frac{dy}{dx} + \frac{1}{c} = 0$  or  $dx + c dy = 0 \Rightarrow x + ct = c_1$   
 $\frac{dy}{dx} - \frac{1}{c} = 0$  or  $dx - c dy = 0 \Rightarrow x - ct = c_2$*

*t = \frac{3\sigma}{2y^2}*  
*here (y=t)*

So, now let us go to the differential equation  $z_{xx} = 1/c^2 z_{tt}$ . So here  $z_{xx} - 1/c^2 z_{tt} = 0$ . We have the standard form of differential equation as  $Rr + Ss + Tt + Fxyzpq = 0$ . So, therefore  $R=1, S=0, T=-1/c^2$ . This is small  $c$ .  $S^2 - 4RT$  is what  $S$  is  $0 - 4R$  is  $1$  okay and  $T$  is  $-1/c^2$ .  $S^2 - 4RT = 4/c^2$  so this is  $> 0$ . So,  $S^2 - 4RT$  is  $> 0$ . Hence the given PDE okay the given PDE is hyperbolic for all  $xy$  for all the points  $xy$ .

Now let us find its characteristics we have  $\lambda$  to be quadratic is given  $R\lambda^2 + S\lambda + T = 0$  okay so  $r=1$  so we have  $\lambda^2 + S = 0$  and  $t = -1/c^2$ . So, we have

$\lambda = \pm 1/c$  okay let  $\lambda_1 xy = 1/c$  and  $\lambda_2 xy = -1/c$  then from  $dy/dx + \lambda_1 xy = 0$ . We have  $dy/dx + \lambda_1 xy = 1/c$  so  $1/c = 0$  or  $dx$ . We have to take  $x$  and  $t$  so that other variable  $y$  is to be replaced with  $T$ .

So, that we can do this I am taking this as  $T$  okay this  $T$  is  $\Delta z / \Delta y$  square in this standard form. Here it is given by small  $t$  here  $y = \text{small } t$   $t$  is the time this is actually one dimensional wave equation where  $t$  represents the time. So,  $y$  is  $t$  here so this is actually  $dx + c dt = 0$  So, this gives you  $x + ct$  as a constant so  $c_1$  other equation is  $dy$  is again  $dt / dx - 1 / c = 0$  or we can say  $dx - c dt = 0$ .

So this gives you  $x - ct = \text{some other constant } c_2$  So  $x + ct = c_1$  and  $x - ct = \text{some other constant } c_2$  They are the families of characteristics in the case of one dimensional wave equation  $\frac{\partial^2 z}{\partial x^2} = \frac{1}{C^2} \frac{\partial^2 z}{\partial t^2}$ . That is all in this lecture, thank you very much for your attention.
