Lecture - 47
Review of Integral Transform- II

Hello Friends, Welcome to my lecture on review of integral transforms II, first we shall look at an application on Laplace transform to heat conduction equation.

(Refer Slide Time: 00:37)

Application of Laplace transform to heat conduction equation:

To determine the flow of heat in a semi-infinite solid, $x > 0$, when initially the solid is at zero temperature, and at $t=0$ the boundary $x=0$ is raised to a temperature u_0 and maintained at u_0 .

Here we have to solve this equation

$$c^2 u_{xx} = u_t$$

$u(x,0) = 0$, \neq initial condition
 $u(0,t) = u_0$, \neq boundary condition

$\int_0^\infty e^{-st} \left(\int_0^\infty e^{-sx^2} \frac{\partial^2 u}{\partial x^2} dx \right) dt = \int_0^\infty e^{-st} \frac{\partial u}{\partial t} dt$

$c^2 \frac{\partial^2}{\partial x^2} \left(\int_0^\infty e^{-st} u(x,t) dt \right) = \left[e^{-st} u(x,t) \right]_0^\infty - \int_0^\infty (-s) e^{-st} u(x,t) dt$

$c^2 \frac{\partial^2 \bar{u}}{\partial x^2} = -u(x,0) + s \bar{u} = s \bar{u}$

$\bar{u}(0,b) = \int_0^\infty e^{-bt} u(0,t) dt = u_0 \int_0^\infty e^{-bt} dt = u_0 \left(\frac{e^{-bt}}{-b} \right)$

$\bar{u}(x,b) = B e^{-x\sqrt{b}/c} \Rightarrow \bar{u}(0,b) = B$

$\frac{\partial^2 \bar{u}}{\partial x^2} = \frac{s}{c^2} \bar{u}$ or $m^2 = \frac{s}{c^2} \Rightarrow m = \pm \frac{\sqrt{s}}{c}$

$\bar{u}(x,b) = A e^{x\sqrt{b}/c} + B e^{-x\sqrt{b}/c}$

As $x \rightarrow \infty$, we must take $A=0$ so that temp remains finite

$\bar{u}(x,b) = B e^{-x\sqrt{b}/c} \Rightarrow \bar{u}(0,b) = B$

$u(x,t)$ temperature in the bar at a distance x and at time t

In the last lecture, we had discussed Laplace transforms. Here is the example on the application of Laplace transform to heat conduction equation. We are going to determine the flow of heat in a semi-infinite and solid when $x > 0$, when initially the solid is at 0 temperature in at $t=0$ and the boundary x is 0 and is raised to a temperature at u_0 and u_0 maintained at u_0 . So, let us assume that $u(x,t)$ denotes the semi-infinite solid at a distance x from one end.

Suppose this is one dimensional bar so here $x=0$. We have an element here x at a distance x , $x=0$ at time t , so we want to determine $u(x,t)$ at the temperature in the bar at a distance x , let me say this is end a and time t . So, we have to solve the first order or say second order differential equation $c^2 u_{xx}$ that is $c^2 u_{xx} = \frac{\partial^2 u}{\partial x^2} = \frac{\partial u}{\partial t}$. So, we have to determine the temperature distribution $u(x,t)$ in the bar.

Here we are giving the initial condition at $t=0$, the solid at 0 temperature so we have given $u_x=0$ for all x . okay At time $t=0$, temperature is 0 and the boundary condition is that $x=0$ is raised to a temperature at u_0 and maintained at u_0 so at $u(0,t)=u_0$ for all the time t okay. So, these are initial condition and we have this as a boundary condition. So, in order to solve this differential equation what we do is we multiply by e to the power st .

And both the sides of the equation and integrated over the interval 0 to infinity. So, what we have $c^2 \int_0^\infty e^{-st} dx = \text{this okay}$. Now since we are integrating x , x and t are independent variables so I can also write it as. Now, here this is a product of 2 functions. Let us integrate the by parts so $e^{-st} * \int \frac{\partial u}{\partial t} dx$ which is $u(x,t) - \int_0^\infty \frac{\partial}{\partial t} (e^{-st}) dx$ which is $-s$.

Now, let us denote, let us say that Laplace transform of $u(x,t)$ is $u(x,s)$. okay, so let us say that the this is the Laplace transform of $u(x,t)$ so we will have here $c^2 u(x,s) = u(x,0) + \int_0^\infty e^{-st} \frac{\partial u}{\partial t} dx$ as t goes to infinity $u(x,t) e^{-st}$ when t goes to infinity goes to 0. Okay this is positive $u(x,t) e^{-st}$ remains goes to 0 because $u(x,t)$ remains I mean finite. So, so this goes to 0 then when $t=0$.

What we get this is $e^{-st} u(x,0) - u(x,0) + s \int_0^\infty e^{-st} u(x,t) dx$ which is the function $u(x,s)$ we get sur. So, so you are given $u(x,0)=0$ so this $=s u(x,s)$ so what do we have or thus we have this one okay. Or we can say it can be regarded as an ordinary differential equation of second order where the variable is s and we are keeping x as constant.

So, this is of the form ordinary equation will be $m^2 - s/c^2 = 0$ if we regard it as ordinary differential equation of second order and $n = \pm \sqrt{s/c}$. Okay so we have $u(x,s) = A e^{-x \sqrt{s/c}} + B e^{x \sqrt{s/c}}$ will be some constant which will depend on s $x e^{-x \sqrt{s/c}} + B e^{x \sqrt{s/c}}$ now then x goes to infinity. We must take $A=0$ in order that $u(x,s)$ does not become infinite okay so to keep $u(x,s)$ finite okay, x tends to infinity.

We must take $A=0$ so that temperature remains finite. Okay So what we have $u(x,0)=B$ times e to the power $-x$ root of s/c . Now let us put $x=0$ means putting $x=0$, we get $u(0,s)=B$. Now let us find $u(0,s)$ so we have $u(0,s)=U_0$ here you put this is your Laplace transform $u(x,s)=\int_0^\infty e^{-st} u(x,t) dt$ put $x=0$ in this so we get $u(0,s)=\int_0^\infty e^{-st} u(0,t) dt$ okay $u(0,t)$ is u_0 .

So, this is u_0 times u_0 is constant so $\int_0^\infty e^{-st} dt$ okay and this is u_0 times e to the power $-st/s$ $\int_0^\infty dt$. So, if s is positive then st goes to infinity this will go to 0 so you will get u_0/s so we get $B=u_0/s$ and therefore what we have so $B=u_0/s$ and hence $u(x,s)=u_0/s * e$ to the power $-x$ root s/c okay so we get this.

(Refer Slide Time: 09:55)

$$\begin{aligned} \bar{u}(x,s) &= \frac{u_0}{s} e^{-x\sqrt{s/c}} \\ \mathcal{L}^{-1}(\bar{u}(x,s)) &= u_0 \mathcal{L}^{-1}\left(\frac{e^{-x\sqrt{s/c}}}{s}\right) \\ \Rightarrow u(x,t) &= u_0 \left(1 - \operatorname{erf}\left(\frac{x}{2c\sqrt{t}}\right)\right) \end{aligned} \qquad \begin{aligned} \bar{u}(x,s) &= \mathcal{L}(u(x,t)) \\ \text{So} \\ \mathcal{L}^{-1}(\bar{u}(x,s)) &= u(x,t) \end{aligned}$$

$$\begin{aligned} \text{Using } \mathcal{L}^{-1}\left(\frac{e^{-b\sqrt{s}}}{s}\right) &= 1 - \operatorname{erf}\left(\frac{b}{2\sqrt{x}}\right), \text{ we have} \\ u &= u_0 \left(1 - \operatorname{erf}\left(\frac{x}{2c\sqrt{t}}\right)\right). \end{aligned}$$

So we get $u(x,s)=u_0/s * e$ to the power $-x$ root s/c . Now let us take inverse Laplace transform of this so \mathcal{L}^{-1} of $u(x,s)=u_0 * \mathcal{L}^{-1}$ of $u_0/s * e^{-x\sqrt{s/c}}$. Now in the last lecture we have found inverse Laplace transform of e to the power $-B$ root $x/s=1-\operatorname{erf}$ function of $\sqrt{2}$ times root x . So, let us apply this result this result we have seen we have proved using the inversion formula in the Laplace transform.

And so this we can use and this will give you and let us note that $u(x,s)=\mathcal{L}$ transform of $u(x,t)$. So, \mathcal{L}^{-1} of $u(x,s)=u(x,t)$ and therefore this will give you $u(x,t)=u_0$. So, now let us compare here

we have root s*-B _ B is replaced by x/c here we can put t instead of x because here we had the function of x so we had this is=1- error function of in place of B we will put x/c.

So, we will have x/2 root c x over 2c root t. Inverse Laplace formula we take uxt in this formula it will give us this. So, this is the solution to the heat equation by using the Laplace transform.

(Refer Slide Time: 12:13)

Fourier Series: Let f be a periodic function of period 2π , which can be represented by a trigonometric series

$$f(x) = \frac{a_0}{2} + \sum_{n=1}^{\infty} (a_n \cos nx + b_n \sin nx) \quad (1)$$

If term by term integration of the series is allowed then we obtain the so called Euler formulas

$$a_k = \frac{1}{\pi} \int_{-\pi}^{\pi} f(x) \cos kx \, dx, \quad k = 0, 1, 2, \dots$$

and $b_k = \frac{1}{\pi} \int_{-\pi}^{\pi} f(x) \sin kx \, dx, \quad k = 1, 2, 3, \dots$ (2)

Now let us consider Fourier series, let f be a period function of period 2π which can be represented/a trigonometric series $fx=a_0/2+\sigma$ infinity to $n=1$ $a_n \cos nx+ b_n \sin nx$. If term/term of this series is allowed, term/term integration is allowed, then we obtain the so called Euler formula. We can see that because we have 1, $\cos x$, $\sin x$, $\cos 2x$, $\sin 2x$ they are all orthogonal functions/the interval- π π to π π , okay.

That means if you take any pair of any 2 functions/the interval of- π to π their product you take and integrate/- π to π , then this integral is always 0. So, what we have from this equation, when you multiply this equation/ $\cos nx$ when you multiply this equation/ $\cos nx$ and integrate/the interval- π to π , then what value will you get an will survive where n will be= m , then only we will get non 0 value here, otherwise it is all 0.

So, we get a_m is arbitrary, so we get $a_k=1/\pi, -\pi$ to π $fx \cos kx \, dx$. This includes this a_0 also. So we have $k=0, 1, 2$. So b_n s are given/the formula $b_k=1/\pi, -\pi$ to π $fx \sin kx \, dx$.

(Refer Slide Time: 13:44)

Note that because of the periodicity of the integrands, the interval of integration in (1) can be replaced by any other interval of length 2π , for instance, by the interval $0 \leq x \leq 2\pi$.

If f is continuous or merely piecewise continuous (continuous except for finitely many finite jumps in the interval of integration), the integrals in (2) exist and hence we may compute $a_k, k = 0, 1, 2, \dots$ and $b_k, k = 1, 2, 3, \dots$ and form the trigonometric series

$$\frac{a_0}{2} + a_1 \cos x + b_1 \sin x + \dots + a_n \cos nx + b_n \sin nx + \dots \quad (3)$$

This series is then called the Fourier series of f and its coefficients

$a_k, k = 0, 1, 2, \dots$ and $b_k, k = 1, 2, 3, \dots$ are called the Fourier coefficients of $f(x)$.

Now, note that because the periodicity of the integrands, you can see $f(x)$ is 2π periodic, $\cos kx$ is 2π periodic, $\sin kx$ is 2π periodic and here $f(x) \cdot \sin kx$ is 2π periodic. So, the interval of the integration can be changed from 0 to π to any interval of length 2π . For example, we can take the interval 0 to 2π . So, because of the periodicity the interval and integration can be replaced by any other interval of length 2π . For instance, $0 \leq x < 2\pi$.

If f is continuous or merely piecewise continuous, piecewise continuity meaning continuous except for finitely many jumps in the interval of integration, the integral of (2) will exist and hence can be evaluated. Hence we compute the values of a_k and b_k . And then form this trigonometric series $a_0/2 + a_1 \cos x + b_1 \sin x$ and so on. This is called the Fourier series of f and the coefficients of a_k and b_k are called the Fourier coefficients of f .

(Refer Slide Time: 14:52)

The following theorem gives sufficient conditions for the representation of a function by a Fourier series.

Theorem: If a periodic function $f(x)$ with period 2π is piecewise continuous in the interval $-\pi \leq x \leq \pi$ and has a left and right hand derivative at each point of that interval, then the corresponding Fourier series (3) with coefficients (2) is convergent. Its sum is $f(x)$, except at a point x_0 at which $f(x)$ is discontinuous and the sum of the series is the average of the left and right hand limits of $f(x)$ at x_0 .

Now the following theorem gives sufficient conditions for the representation of a function/a Fourier series. Now let us look at the question of the convergence of this Fourier series. When the Fourier series converge and if it converges whether it represents the function $f(x)$ or x_0 . So, this theorem gives us the sufficient conditions for the convergence of the Fourier series. If a periodic function $f(x)$ with a period 2π is piecewise continuous.

In the interval $-\pi$ to π and has a left and right hand derivative at each point of the interval, then the corresponding Fourier series (3) with coefficients (2) is convergent. This series is convergent and its coefficients are given by these formulas. These formulas are called as Euler's formulas. Its sum is $f(x)$. So, the sum of the series will be $f(x)$ at each point of continuity of f and at the point of discontinuity.

Its sum will be equal to the average of left hand and the right hand limits, so at the point of x_0 . So $f(x_0^+)$ and $f(x_0^-)/2$. So, these conditions are known as (Dini) (15:55) conditions and almost every function $f(x)$ of period 2π can be represented by Fourier series that we come across applications.

(Refer Slide Time: 16:11)

Example: Consider the function

$$f(x) = \begin{cases} -k, & \text{when } -\pi < x < 0 \\ k, & \text{when } 0 < x < \pi \end{cases},$$

and

$$f(x + 2\pi) = f(x).$$

$$\begin{aligned} a_0 &= \frac{1}{\pi} \int_{-\pi}^{\pi} f(x) dx = 0 \\ a_n &= \frac{1}{\pi} \int_{-\pi}^{\pi} f(x) \cos nx dx = 0, \quad \forall n=1, 2, \dots \\ b_n &= \frac{1}{\pi} \int_{-\pi}^{\pi} f(x) \sin nx dx \\ &= \frac{2}{\pi} \int_0^{\pi} f(x) \sin nx dx = \frac{2k}{\pi} \int_0^{\pi} \sin nx dx = \frac{2k}{\pi} \left(-\frac{\cos nx}{n} \right)_0^{\pi} = \frac{2k}{\pi} \left(\frac{1 - \cos n\pi}{n} \right) \\ &= \frac{2k}{\pi} \left(\frac{1 - (-1)^n}{n} \right) = \begin{cases} 0, & n \text{ is even integer} \\ \frac{4k}{n\pi}, & n \text{ is odd integer} \end{cases} \quad n = 2m-1 \\ \frac{a_0}{2} + \sum_{n=1}^{\infty} (a_n \cos nx + b_n \sin nx) &= \sum_{n=1}^{\infty} b_n \sin nx = \sum_{m=1}^{\infty} \frac{4k}{(2m-1)\pi} \sin (2m-1)x \end{aligned}$$

So consider the function $f(x) = -k$ when $-\pi < x < 0$ and $f(x) = k$ where $0 < x < \pi$. Now let us see the graph of this function. See $-\pi$ to 0 it is $-k$. Let us take k positive and draw the graph like this. And then, from 0 to π it is k . Okay. And then it is extended to π periodicity like this. So, you can see that, this is an odd function okay $f(x)$ is an odd function here that is $f(-x) = -f(x)$, we can see that. If we look at the Euler's formula, Euler's formula for a_k , $a_0 = \frac{1}{\pi} \int_{-\pi}^{\pi} f(x) dx$.

Since $f(x)$ is an odd function, $\int_{-\pi}^{\pi} f(x) dx$ will be 0 . So $a_0 = 0$, and then the value of $a_n = \frac{1}{\pi} \int_{-\pi}^{\pi} f(x) \cos nx dx$. Since f is an odd function $\cos nx$ is even function, their product is an odd function, and therefore this integral will be 0 and this is 0 for all $n=1, 2, 3$ and so on. So now, let us look at the formula for b_n . $b_n = \frac{1}{\pi} \int_{-\pi}^{\pi} f(x) \sin nx dx$. So here $f(x)$ is odd function and $\sin nx$ is odd function.

So, their product is even. So I can write $\frac{2}{\pi} \int_0^{\pi} f(x) \sin nx dx$. Now interval 0 to π $f(x) = k$. So we can write it as $\frac{2k}{\pi} \int_0^{\pi} \sin nx dx$. And this will be $\frac{2k}{\pi} \int_0^{\pi} \sin nx dx$. $\int_0^{\pi} \sin nx dx$ will be $-\frac{\cos nx}{n}$ so 0 to π , we will get $-\frac{\cos n\pi}{n} + \frac{\cos 0}{n} = \frac{1 - \cos n\pi}{n}$. So this is therefore $= \frac{2k}{\pi} \frac{1 - \cos n\pi}{n}$. So this is equal to if n is even, this will be $1 - 1$ so 0 , if n is even integer and this will be 2 if n is odd. So it is $\frac{4k}{n\pi}$ when n is odd integer.

So, we can now write the Fourier series for the function f . Our Fourier series is, $\frac{a_0}{2} + \sum_{n=1}^{\infty} (a_n \cos nx + b_n \sin nx)$. So this is given a_0 is 0 , a_n are 0 , so $\sum_{n=1}^{\infty} b_n \sin nx$.

$b_n \sin nx$. B_n is $=4k/\pi$ when n is odd integer. So, replacing $n/2m-1$, where m will take values $0,1,2$ and so on. So, we will get $\sum_{m=1}^{\infty} \frac{4k}{2m-1} \sin(2m-1)x$.

Or I can write it as $4k/\pi$, as $4k/\pi$ is a constant $\sum_{n=1}^{\infty} \frac{\sin(2n-1)x}{2n-1}$. This is the Fourier series for the function f . And its sum is $=fx$ over the points of continuities and the points of discontinuities at the average of left hand and right hand limits.

(Refer Slide Time: 21:26)

Hence the Fourier series of f is given by

$$f(x) = \frac{4k}{\pi} \sum_{k=1}^{\infty} \frac{\sin(2k-1)x}{2k-1}, \quad \text{for } -\pi < x < 0 \text{ and } 0 < x < \pi. \quad (4)$$

At $x = 0, \pm\pi$, the sum of the series is the average of the left and right hand limits of $f(x)$.

If we take $x = \frac{\pi}{2}$, then from (4)

$$f\left(\frac{\pi}{2}\right) = \frac{4k}{\pi} \sum_{k=1}^{\infty} \frac{\sin(2k-1)\frac{\pi}{2}}{2k-1}$$

and so

$$1 - \frac{1}{3} + \frac{1}{5} - \frac{1}{7} + \dots = \frac{\pi}{4}$$

So the Fourier series is given by $-\pi < x < 0$ because f is continuous here and $0 < x < \pi$ where also the function is continuous. The discontinuity points you can see in the interval $-\pi$ to π the discontinuities occur at $-\pi$, 0 and π . So, the sum of the series here is the average of left hand and the right limits of fx . Now let us look at the particular case suppose if I take $x = \pi/2$. At $x = \pi/2$ what do we notice at $x = \pi/2$.

Function is continuous and it takes value k okay and so since function is continuous fx will be this series okay. So, we will have $f(\pi/2) = 4k/\pi \sum_{k=1}^{\infty} \frac{\sin(2k-1)\pi/2}{2k-1}$. So, then what do you see is that $f(\pi/2) = k = 4k/\pi \sum_{n=1}^{\infty} \frac{\sin(2n-1)\pi/2}{2n-1}$.

This k will cancel with k and we will have $\sum_{n=1}^{\infty} \frac{\sin(2n-1)\pi/2}{2n-1} = \pi/4$, Okay and $\sin(2n-1)\pi/2 = \sum_{n=1}^{\infty} \frac{1}{2n-1}$. So this is $\pi/4$ then we

get $1-1/3 + 1/5 - 1/7$ and so on $= \pi/4$. So, by using the Fourier series we can also find the sum of series of cosine terms in some particular cases. Now let us discuss Fourier series of functions having arbitrary period.

(Refer Slide Time: 23:55)

Fourier series of functions having arbitrary period:

In applications, periodic functions rarely have period 2π . Therefore in order to find the Fourier series of a periodic function $f(t)$ with period, say T , we use the change of scale. We introduce a new variable x such that $f(t)$ as

a function of x , has period 2π . Let us define $t = \frac{T}{2\pi} x$ then $x = \pm \pi$

corresponds to $t = \pm \frac{T}{2}$ and $f(t) = f\left(\frac{T}{2\pi} x\right) = \phi(x)$, say.

Then $\phi(x + 2\pi) = \phi(x)$. So we can find the Fourier coefficients for the function ϕ by the Euler's formulas

$$a_k = \frac{1}{\pi} \int_{-\pi}^{\pi} \phi(x) \cos kx dx, k = 0, 1, 2, \dots$$

In applications periodic functions rarely have period 2π therefore in order to find the Fourier series of a periodic function $f(t)$ with period say T , we use the change of the scale. We introduce a new variable x such that $f(t)$ as a function of x has period 2π . So, let us define $T = T/2 \pi * x$, then x will take value $+\pi$ T will take values $+T/2$. So $f(t) = f(t/2\pi * x)$ which is the function of x let us call it as $\phi(x)$.

Then becomes the 2π periodic function, you can easily check that $\phi(x + 2\pi) = \phi(x)$ and this is $f(t)$ upon $2\pi + T$. Since f is periodic with period T this will be f of Tx upon 2π and which is $\phi(x)$. So, ϕ is the periodic function with period 2π and so we can find the Euler's formula for the function ϕ by writing Euler's formula for the function ϕ . We can determine the coefficients of the Fourier series for the function ϕ $a_k = 1/\pi \int_{-\pi}^{\pi} \phi(x) \cos kx dx$ $k=0, 1, 2$ and so on.

(Refer Slide Time: 25:28)

and
$$b_k = \frac{1}{\pi} \int_{-\pi}^{\pi} \phi(x) \sin kx \, dx, k = 1, 2, \dots$$

or
$$a_k = \frac{1}{\pi} \int_{-\pi}^{\pi} f\left(\frac{T}{2\pi}x\right) \cos kx \, dx, k = 0, 1, 2, \dots$$

and
$$b_k = \frac{1}{\pi} \int_{-\pi}^{\pi} f\left(\frac{T}{2\pi}x\right) \sin kx \, dx, k = 1, 2, \dots$$

Now, since $x = \frac{2\pi}{T}t$, we have $dx = \frac{2\pi}{T}dt$ hence

And When $b_k = 1/\pi \int_{-\pi}^{\pi} \phi(x) \sin kx \, dx$, $k = 1, 2$ and so on and now here $a_k =$ let us put the value of

(Refer Slide Time: 25:42)

and
$$b_k = \frac{1}{\pi} \int_{-\pi}^{\pi} \phi(x) \sin kx \, dx, k = 1, 2, \dots$$

or
$$a_k = \frac{1}{\pi} \int_{-\pi}^{\pi} f\left(\frac{T}{2\pi}x\right) \cos kx \, dx, k = 0, 1, 2, \dots$$

and
$$b_k = \frac{1}{\pi} \int_{-\pi}^{\pi} f\left(\frac{T}{2\pi}x\right) \sin kx \, dx, k = 1, 2, \dots$$

Now, since $x = \frac{2\pi}{T}t$, we have $dx = \frac{2\pi}{T}dt$ hence

Let us replace $\pi x/FT/2\pi$ then we will get $a_k = 1/\pi \int_{-T/2}^{T/2} f(x) \cos kx \, dx$, $k = 0, 1, 2$ and so on and here $b_k = 1/\pi \int_{-T/2}^{T/2} f(x) \sin kx \, dx$, $k = 1, 2$ and so on. Now since $x = 2\pi t/T$ let us the value of $x = 2\pi t/T$ then this f becomes f_t . So, and $\sin kx$ and k will be t will be $x = 2\pi t/T$. so $dx = 2\pi/T dt$ and the limits of integration will change from $-\pi$ to $-T/2$ to $T/2$ and we will have these formulas.

(Refer Slide Time: 26:34)

$$a_k = \frac{2}{T} \int_{-T/2}^{T/2} f(t) \cos \frac{2\pi kt}{T} dt, k=0,1,2, \dots \quad (5)$$

and
$$b_k = \frac{2}{T} \int_{-T/2}^{T/2} f(t) \sin \frac{2\pi kt}{T} dt, k=1,2, \dots$$

The Fourier series of $f(t)$ becomes

$$\frac{a_0}{2} + \sum_{n=1}^{\infty} \left(a_n \cos \frac{2\pi nt}{T} + b_n \sin \frac{2\pi nt}{T} \right)$$

The interval of integration in (5) may be replaced by any interval of length T for instance $0 \leq t \leq T$.

$a_k = 2/T \int_{-T/2}^{T/2} f(t) \cos 2\pi kt/T, k=0,1,2$ and so on $b_k = 2/T \int_{-T/2}^{T/2} f(t) \sin 2\pi kt/T, k=1,2$ and so on. The Fourier series of $f(t)$ now becomes $a_0/2 + \sum_{k=1}^{\infty} a_k \cos 2\pi kt/T + b_k \sin 2\pi kt/T$, which was Fourier series from the function $f(t)$.

(Refer Slide Time: 27:09)

and
$$b_k = \frac{1}{\pi} \int_{-\pi}^{\pi} \phi(x) \sin kx dx, k=1,2, \dots$$

or
$$a_k = \frac{1}{\pi} \int_{-\pi}^{\pi} f\left(\frac{T}{2\pi}x\right) \cos kx dx, k=0,1,2, \dots$$

and
$$b_k = \frac{1}{\pi} \int_{-\pi}^{\pi} f\left(\frac{T}{2\pi}x\right) \sin kx dx, k=1,2, \dots$$

Handwritten notes in red:
 $\frac{a_0}{2} + \sum_{k=1}^{\infty} \left[\frac{a_k \cos kx + b_k \sin kx}{k} \right]$
 $\frac{a_0}{2} + \sum_{k=1}^{\infty} \left[\frac{a_k \cos \frac{2\pi kt}{T} + b_k \sin \frac{2\pi kt}{T}}{k} \right]$

Now, since $x = \frac{2\pi}{T}t$, we have $dx = \frac{2\pi}{T}dt$ hence

Is $a_0/2 + \sum_{k=1}^{\infty} a_k \cos nx + b_k \sin nx$ these are Fourier functions $f(t)$ of the series. So, let us put $x = 2\pi T/t$ to get the Fourier function of the s . So, $a_0/2 + \sum_{k=1}^{\infty} a_k \cos 2\pi kt/T + b_k \sin 2\pi kt/T$.

(Refer Slide Time: 28:01)

$$a_k = \frac{2}{T} \int_{-T/2}^{T/2} f(t) \cos \frac{2\pi kt}{T} dt, k=0,1,2, \dots \quad (5)$$

and

$$b_k = \frac{2}{T} \int_{-T/2}^{T/2} f(t) \sin \frac{2\pi kt}{T} dt, k=1,2, \dots$$

The Fourier series of $f(t)$ becomes

$$\frac{a_0}{2} + \sum_{n=1}^{\infty} \left(a_n \cos \frac{2\pi nt}{T} + b_n \sin \frac{2\pi nt}{T} \right)$$

The interval of integration in (5) may be replaced by any interval of length T for instance $0 \leq t \leq T$.

We can find the periodic function for any Fourier series with period T . so this is the Fourier series the interval of integration here again since a period $T \cos 2\pi kt/T$ is also period T . So, the integrant of periodic function with period T so we can change the interval of integration from $-T/2$ to $T/2$ any interval of length T for example 0 to T . So, in place of $T/2$ to $-T/2$ we can also write integral over 0 to T in the Eulers formula for f_t .

(Refer Slide Time: 28:40)

Example: Let

$$f(t) = \begin{cases} 0, & \text{when } -2 < t < -1 \\ k, & \text{when } -1 < t < 1 \\ 0, & \text{when } 1 < t < 2 \end{cases}$$

and $T = 4$, then the Fourier series of f is given by

$$f(t) = \frac{k}{2} + \frac{2k}{\pi} \left(\cos \frac{\pi t}{2} - \frac{1}{3} \cos \frac{3\pi t}{2} + \frac{1}{5} \cos \frac{5\pi t}{2} - \dots \right)$$

Handwritten notes:

- $f(t) = \frac{a_0}{2} + \sum_{n=1}^{\infty} \left(a_n \cos \frac{2\pi nt}{T} + b_n \sin \frac{2\pi nt}{T} \right)$
- f is an even function
- $f(t+4) = f(t)$
- $b_n = \frac{2}{T} \int_{-T/2}^{T/2} f(t) \sin \frac{2\pi nt}{T} dt = 0, \forall n=1,2, \dots$
- $a_0 = \frac{2}{T} \int_{-T/2}^{T/2} f(t) dt = \frac{2}{4} \int_{-1}^1 k dt = \frac{k}{2}$
- $a_n = \frac{2}{T} \int_{-T/2}^{T/2} f(t) \cos \frac{2\pi nt}{T} dt = \frac{2}{4} \int_{-1}^1 k \cos \frac{2\pi nt}{4} dt = \frac{k}{2} \int_{-1}^1 \cos \frac{\pi nt}{2} dt = k \left(\frac{\sin \pi n t}{\pi n} \right) \Big|_{-1}^1 = k \left(\frac{\sin \pi n - \sin(-\pi n)}{\pi n} \right) = k \left(\frac{0 - 0}{\pi n} \right) = 0$

Now let us say for example function for $0-2 < t < -1 < k$ $1-t < 1 < t < t$ let us draw the graph of this s. so here this is $-1, -2$. So, from -2 to -1 the function is 0 and when -1 to 1 , it takes the value of k and from 1 to 2 also it is 0 this one okay. You can see here and then $T=4$ okay so it is the periodic

function with period 4 $f(t+4)=f(t)$ that is given to us. So, if you look at the graph of this function over -2 to 2 we see that the function f is an even function.

When f is an even function if we look at the Eulers formula for $b_n = \frac{1}{\pi} \int_{-\pi}^{\pi} f(t) \sin nt dt$ this is in the case of 2π periodic function but we have a T periodic function then b_n we have to write as $\frac{2}{T} \int_{-T/2}^{T/2} f(t) \sin \frac{2\pi kt}{T} dt$. Let us use this formula, let us use $b_n = \frac{2}{T} \int_{-T/2}^{T/2} f(t) \sin \frac{2\pi nt}{T} dt$. Let us use this formula for b_n why I am writing this formula for b_n first because you will see that $b_n = 0$ for all n .

Since f is an even function and $\sin \frac{nt}{T}$ is an odd function. So, the product in an odd function is therefore $\int_{-T/2}^{T/2} f(t) \sin \frac{2\pi nt}{T} dt = 0$, these 0 for all n . so we need to calculate only a_0 and a_n . $a_0 = \frac{2}{T} \int_{-T/2}^{T/2} f(t) dt$. So $T=4$ $\frac{2}{4} \int_{-2}^{2} f(t) dt$. Since f is an even function I can write it as $2 \int_0^2 f(t) dt$. so that means $\frac{4}{4} \int_0^2 f(t) dt$ and then this is $\frac{4}{4} \int_0^2 f(t) dt = \int_0^2 f(t) dt$.

So, we have $\int_0^1 k dt$ and so this is k and $\int_1^2 0 dt$ so we have 0 So it is k . Similarly, we can find $a_n = \frac{2}{T} \int_{-T/2}^{T/2} f(t) \cos \frac{2\pi nt}{T} dt$ this is again $T=4$ so $\frac{2}{4}$ and integral is over -2 to 2 $\int_{-2}^2 f(t) \cos \frac{2\pi nt}{4} dt$ f is an even function \cos is also an even function. So, we get $\int_{-2}^2 f(t) \cos \frac{2\pi nt}{4} dt = 2 \int_0^2 f(t) \cos \frac{2\pi nt}{4} dt$ Over 0 to 1 function is k and over 1 to 2 function is 0 .

So, we can write $\int_0^1 k \cos \frac{\pi nt}{2} dt$ and this is $k \int_0^1 \cos \frac{\pi nt}{2} dt$ upon n $\frac{\pi n}{2}$ and their limits are 0 to 1 , So we get $T=0$ $\sin \frac{\pi nt}{2} / \frac{\pi n}{2}$ but when $t=0$ we get $\sin \frac{\pi n}{2}$ so we get $\frac{2k}{\pi n} \sin \frac{\pi n}{2}$. So when $n=1$ we get $\sin \frac{\pi}{2}$ so this is $\frac{2k}{\pi}$. When $n=2$ $\sin \pi = 0$ so this is 0 when n is even when n is odd say $1, 3, 5, 7$ we will get $\sin \frac{3\pi}{2}$ is -1 so -1 to the power $n-1$ when n is odd this is multiplied by $\frac{2k}{\pi}$ that is $\frac{2k}{\pi n}$.

So, what do we get here $f(t)$ is $\frac{a_0}{2} + \sum_{n=1}^{\infty} a_n \cos \frac{2\pi nt}{T} + \sum_{n=1}^{\infty} b_n \sin \frac{2\pi nt}{T}$. So, $b_n = 0$ $a_0 = k$ and we get $\frac{k}{2}$ when we put the value of a_n from here to get this cosine series. So, $f(t)$ because f is a living function so $f(t)$ the Fourier series of f is even.

(Refer Slide Time: 35:21)

Fourier series of even and odd functions : The Fourier series of an even function $f(t)$ of period T is a "Fourier cosine series"

$$\frac{a_0}{2} + \sum_{n=1}^{\infty} \left(a_n \cos \frac{2\pi nt}{T} \right)$$

with $a_k = \frac{2}{T} \int_{-T/2}^{T/2} f(t) \cos \frac{2\pi kt}{T} dt, k = 0, 1, 2, \dots$

The Fourier series of an odd function of an odd function $f(t)$ of period T is a "Fourier sine series"

$$\sum_{n=1}^{\infty} b_n \sin \frac{2\pi nt}{T}$$

Now let us consider Fourier series of even and odd functions which we have already seen Fourier series of even function f of t is a Fourier Cosine Series $a_0/2 + \sum_{n=1}^{\infty} a_n \cos 2\pi nt/T$ with a_n is given by $2/T \int_{-T/2}^{T/2} f(t) \cos 2\pi kt/T dt$. And taking values 0 1 2 etc the Fourier series of an odd function $f(t)$ of period T is Fourier sine series $\sum_{n=1}^{\infty} b_n \sin 2\pi nt/T$ as we have seen earlier.

(Refer Slide Time: 35:55)

with $b_k = \frac{2}{T} \int_{-T/2}^{T/2} f(t) \sin \frac{2\pi kt}{T} dt, k = 1, 2, \dots$

Theorem: The Fourier coefficients of a sum $f_1 + f_2$ are the sums of the Fourier coefficients of f_1 and f_2 .

$$a_0 = \frac{2}{T} \int_{-T/2}^{T/2} (f_1 + f_2) dt = \frac{2}{T} \int_{-T/2}^{T/2} f_1 dt + \frac{2}{T} \int_{-T/2}^{T/2} f_2 dt$$

$$a_n = \frac{2}{T} \int_{-T/2}^{T/2} (f_1 + f_2) \cos \frac{2\pi nt}{T} dt = \frac{2}{T} \int_{-T/2}^{T/2} f_1 \cos \frac{2\pi nt}{T} dt + \frac{2}{T} \int_{-T/2}^{T/2} f_2 \cos \frac{2\pi nt}{T} dt$$

Where b_n are given by $2/T \int_{-T/2}^{T/2} f(t) \sin 2\pi kt/T dt$ and taking values 1 2 and so on the Fourier coefficients of sum $f_1 + f_2$ are the sums of the Fourier coefficients of f_1 and f_2 . It is very easy to see Suppose the Fourier sums of f_1 and f_2 are $a_0/2 + \sum_{n=1}^{\infty} a_n \cos 2\pi nt/T$.

Let us assume that $f_1 + f_2$ are periodic function with period T . So, here let us begin with a 0 A_0 is $\frac{2}{T} \int_{-T/2}^{T/2} (f_1 + f_2) dt$.

So, we can write it as $\frac{2}{T} \int_{-T/2}^{T/2} f_1(t) dt + \frac{2}{T} \int_{-T/2}^{T/2} f_2(t) dt$. So, the Fourier coefficient a_0 from the function $f_1 + f_2$ are the sum of coefficients of the function f_1 and f_2 . Similarly, we can write $a_n = \frac{2}{T} \int_{-T/2}^{T/2} (f_1 + f_2) \cos \frac{2\pi n t}{T} dt$. This becomes $\frac{2}{T} \int_{-T/2}^{T/2} f_1(t) \cos \frac{2\pi n t}{T} dt + \frac{2}{T} \int_{-T/2}^{T/2} f_2(t) \cos \frac{2\pi n t}{T} dt$. I will have formulae for f_1 coefficient of $\cos \frac{2\pi n t}{T}$ in the Fourier series of F and t .

And this is the coefficient of $\cos f$ in the coefficient of cosine terms in the series of the function f_2 . So, a_n is given by the sum of coefficients of f_1 and f_2 they are the 2 functions for cosine terms. Similarly we can show for b_n b_n are also sums of the corresponding Fourier coefficients of sin terms in f_1 and f_2 .

(Refer Slide Time: 38:49)

Half range expansions: In various physical and engineering problems we need to find the Fourier series of a function $f(t)$ which is defined on some finite interval, say $0 \leq t \leq l$. As it is immaterial whatever the function may be outside the range $0 \leq t \leq l$ so we extend the function to cover the range $-l \leq t \leq l$ so that the new function may be odd or even. The Fourier expansion of such a function of half the period, therefore, consists of sine or cosine terms only. Let $f_1(t)$ denote an odd periodic extension of f . Since $T = 2l$, the Fourier series of $f_1(t)$ is given by

$$\sum_{n=1}^{\infty} b_n \sin \frac{2\pi n t}{T}$$

or

$$\sum_{n=1}^{\infty} b_n \sin \frac{\pi n t}{l} \quad (6)$$

Now we see half range expansions in various physical and engineering problems we need to find the Fourier series of function $f(t)$ which is defined on some finite interval say $0 \leq t \leq l$ as it is immaterial. Whatever the function may be outside the range $0 \leq t \leq l$ so we extend the function to cover the interval $-l$ to l so that the new function may be odd or even. The Fourier expansion of such a function of half the period therefore consists of sin or cosine terms only.

Because if we extend it by taking odd function then we will get the Fourier series of function $f_1(t)$ consisting of sin terms. If we consider the even extension then the function will consist of cosine terms. So, let $f_1(t)$ denote an odd periodic extension of f since $T=2l$ the Fourier series of $f_1(t)$ is given as $\sum_{n=1}^{\infty} b_n \sin \frac{2\pi n t}{T}$ now here $T=2l$ so we get $\sum_{n=1}^{\infty} b_n \sin \frac{\pi n t}{l}$.

(Refer Slide Time: 40:00)

where

$$b_n = \frac{2}{T} \int_{-T/2}^{T/2} f_1(t) \sin \frac{2\pi n t}{T} dt$$

$$= \frac{2}{l} \int_0^l f(t) \sin \frac{\pi n t}{l} dt \quad n=1,2,3,\dots$$

In the case of an even periodic extension $f_1(t)$ of $f(t)$, we have

$$a_n = \frac{2}{T} \int_{-T/2}^{T/2} f_1(t) \cos \frac{2\pi n t}{T} dt$$

$$= \frac{2}{l} \int_0^l f(t) \cos \frac{\pi n t}{l} dt.$$

$b_n = \frac{2}{l} \int_0^l f(t) \sin \frac{\pi n t}{l} dt$ so we can put the values of t we get $\frac{2}{l}$ integral over. Now $f_1(t)$ is an odd function sine is an odd function product is even so we can write it as $\sin \frac{\pi n t}{l}$ and this will be 0 to l here we will have $\frac{4}{l}$ and 0 to l by $\sin \frac{\pi n t}{l} dt$. Here in the case of living periodic extension $f_1(t)$ of $f(t)$ $f_1(t)$ is even cos sin is even so this has been $\frac{4}{l}$ and this means $t=12$ so $\frac{2}{l}$ 0 to T $f(t) \cos \frac{\pi n t}{l} dt$.

(Refer Slide Time: 40:54)

The Fourier series is given by

$$\frac{a_0}{2} + \sum_{n=1}^{\infty} a_n \cos \frac{n\pi t}{l} \quad (7)$$

The series (6) and (7) are called the half range sine and cosine series of f respectively.

Example: Let $f(t) = t, 0 < t < 2$.

Then the half range sine series of f is given by

$$f(t) = \frac{4}{\pi} \left(\sin \frac{\pi t}{2} - \frac{1}{2} \sin \frac{2\pi t}{2} + \frac{1}{3} \sin \frac{3\pi t}{2} - \dots \right) \text{ for } 0 < t < 2.$$

Fourier series is given by $\frac{a_0}{2} + \sum_{n=1}^{\infty} a_n \cos \frac{n\pi t}{l}$ the series 6 and 7 are called the half range sine and cosine series of f respectively. For example, if we take $f(t) = t, 0 < t < 2$ then the half range sine series of f is given we consider an odd periodic extension of $f(t)$ and then we consider an odd periodic function of t then the Fourier series of $f(t)$ will be considered and consist of only sin terms.

We can evaluate the values of b_n by this formulae coefficients of $\sin \frac{n\pi t}{l}$ here so $\sin \frac{n\pi t}{2}$ okay. So, the coefficient of $\sin \frac{n\pi t}{2}$ can be evaluated by this formula $\frac{2}{l} \int_0^l f(t) \sin \frac{n\pi t}{l} dt$. And we can easily show that the half range sine series of f is given by this.

(Refer Slide Time: 42:01)

and the half range cosine series of f is given by

$$1 - \frac{8}{\pi^2} \sum_{n=1}^{\infty} \frac{1}{(2n-1)^2} \cos \frac{(2n-1)\pi t}{2}, \quad 0 < t < 2.$$

And Similarly we can find the half range cosine series of f to get the half range cosine series of f we consider even periodic extension of f. And when we consider even periodic extension of f we apply this formula $a_n = \frac{2}{l} \int_0^l f(t) \cos \frac{n\pi t}{l} dt$ over l from 0 to l So let us see how we get this we can show one of the 2

(Refer Slide Time: 42:32)

$$\begin{aligned}
 a_n &= \frac{2}{l} \int_0^l f(t) \cos \frac{n\pi t}{l} dt \\
 &= \frac{2}{2} \int_0^2 f(t) \cos \frac{n\pi t}{2} dt \\
 &= \int_0^2 t \cos \frac{n\pi t}{2} dt \\
 &= \left(t \frac{\sin \frac{n\pi t}{2}}{\frac{n\pi}{2}} \right) \Big|_0^2 - \int_0^2 \frac{2}{n\pi} \sin \frac{n\pi t}{2} dt \\
 &= \frac{-2}{n\pi} \frac{2}{n\pi} \left(-\cos \frac{n\pi t}{2} \right) \Big|_0^2 \\
 &= -\frac{4}{n^2 \pi^2} (1 - \cos n\pi)
 \end{aligned}$$

and the half range cosine series of f is given by

$$1 - \frac{8}{\pi^2} \sum_{n=1}^{\infty} \frac{1}{(2n-1)^2} \cos \frac{(2n-1)\pi t}{2}, \quad 0 < t < 2.$$

So $a_n = \frac{2}{l} \int_0^l f(t) \cos \frac{n\pi t}{l} dt$ with this function defined about 0 to 2 so $l=2$ so we get 2 integral over 2 $f(t) \cos \frac{n\pi t}{2} dt$. And this is therefore 0 to 2 and the interval 0 to 2 $f(t)$ is defined as t so we can write it as $t \cos \frac{n\pi t}{2}$. Now we can integrate it by parts okay so we get t times $\frac{\sin \frac{n\pi t}{2}}{\frac{n\pi}{2}}$ over $n\pi$ from 0 to 2 and then $-\frac{2}{n\pi} \sin \frac{n\pi t}{2}$ and we get the derivative of t is 1 so $\frac{2}{n\pi} \sin \frac{n\pi t}{2} dt$.

Okay so when you put $T=2$ we get $\sin n\pi$ so that will be 0 when we put 0 that is 0 and we get $-\frac{2}{n\pi} \cos n\pi$ and integral of $\sin n\pi \frac{T}{2} = \frac{2}{n\pi}$ over $n\pi$ again and $-\cos$ and $\frac{2}{n\pi}$ from 0 to 2. Okay So we get $-\frac{4}{n^2 \pi^2} (1 - \cos n\pi)$ when n is even this will be 0 and when n is odd it will be $\frac{8}{n^2 \pi^2}$ okay So we can calculate the Fourier sin series for f.

(Refer Slide Time: 44:14)

Complex form of Fourier series: The Fourier series of a periodic function $f(t)$ of period T is given by

$$f(t) = \frac{a_0}{2} + \sum_{n=1}^{\infty} \left(a_n \cos \frac{2n\pi t}{T} + b_n \sin \frac{2n\pi t}{T} \right) \quad (8)$$

Since $\cos \theta = \frac{e^{i\theta} + e^{-i\theta}}{2}$ and $\sin \theta = \frac{e^{i\theta} - e^{-i\theta}}{2i}$

then (8) may be written as

$$f(t) = c_0 + \sum_{n=1}^{\infty} \left(c_n e^{2in\pi t/T} + c_{-n} e^{-2in\pi t/T} \right) = \sum_{n=-\infty}^{\infty} c_n e^{2in\pi t/T}, \quad (9)$$

This complex of the Fourier series of the function f : The Fourier series of a periodic function of period t is given by $a_0/2 + \sum_{n=1}^{\infty} n \cos 2\pi n \pi t / t + b_n \sin n \pi t / t$. Let us put $\cos \theta = \frac{e^{i\theta} + e^{-i\theta}}{2}$ and $\sin \theta = \frac{e^{i\theta} - e^{-i\theta}}{2i}$. Then the quotient 8 can be written like this so let us see how we get this.

(Refer Slide Time: 44:51)

$$\begin{aligned} f(t) &= \frac{a_0}{2} + \sum_{n=1}^{\infty} a_n \left(\frac{e^{i(2n\pi t/T)} + e^{-i(2n\pi t/T)}}{2} \right) + b_n \left(\frac{e^{i(2n\pi t/T)} - e^{-i(2n\pi t/T)}}{2i} \right) \\ &= \frac{a_0}{2} + \sum_{n=1}^{\infty} \left[\frac{1}{2} (a_n - ib_n) e^{2in\pi t/T} + \frac{(a_n + ib_n)}{2} e^{-2in\pi t/T} \right] \\ &= \frac{a_0}{2} + \sum_{n=1}^{\infty} (c_n e^{2in\pi t/T} + c_{-n} e^{-2in\pi t/T}) \\ &= \sum_{n=-\infty}^{\infty} c_n e^{2in\pi t/T} \end{aligned}$$

$c_0 = \frac{a_0}{2}$
 $c_n = \frac{a_n - ib_n}{2}$
 $c_{-n} = \frac{a_n + ib_n}{2}$

We write $f(t) = a_0/2 + \sum_{n=1}^{\infty} n \cos 2\pi n \pi t / t + b_n \sin n \pi t / t$. So, an e to the power $i\theta$ where θ is $2\pi n \pi t / T$ so $2\pi n \pi t / T + e$ raised to the power $-i 2\pi n \pi t / T$ and t / T . And then we have $b_n e$ raised to the power i times $2\pi n \pi t / T - e$ raised to the power $-i 2\pi n \pi t / T$ over $2i$ okay. So, this is what we have and then we collect the coefficient of e to the power $2i n \pi t / T + e$ to the power of $2i n \pi t / T$ okay,

We will get this form this will be $=a_0/2 + \sum_{n=1}^{\infty} 1/2$ and now 1 over i is $-i$ so $-ib_n$ e to the power $2\pi i n t/T$ okay. And then here whenever i is $-i$ we will get $a_n + ib_n/2$ e to the power $2\pi i n t/T$ with the negative sign okay. So if I write this as c_n and this as $-c_n$ so we get $a_0/2 + \sum_{n=1}^{\infty} c_n e^{2\pi i n t/T} + \sum_{n=1}^{\infty} -c_n e^{-2\pi i n t/T}$ okay. So let me write $c_0 = a_0/2$, $c_n = (a_n + ib_n)/2$ and $c_{-n} = (a_n - ib_n)/2$ okay. Let us see what we have defined.

$c_0 = a_0/2$, $c_n = (a_n + ib_n)/2$ and $c_{-n} = (a_n - ib_n)/2$ Let us choose like this this is $a_n - ib_n$ and this is $a_n + ib_n$. Then we will get here $c_n e^{2\pi i n t/T}$ and this will be $c_{-n} e^{-2\pi i n t/T}$ and we are able to write it as $\sum_{n=-\infty}^{\infty} c_n e^{2\pi i n t/T}$ with this choice where c_n s are given by this expression.

(Refer Slide Time: 48:02)

where,

$$c_0 = \frac{a_0}{2}, c_n = \frac{(a_n - ib_n)}{2} \text{ and } c_{-n} = \frac{(a_n + ib_n)}{2}$$

and hence
$$c_n = \frac{1}{T} \int_{-T/2}^{T/2} f(t) e^{-2\pi i n t/T} dt, n = 0, \pm 1, \pm 2, \dots \quad (10)$$

(9) is known as the complex form of the Fourier series of f and its coefficients are given by (10).

The complex form of Fourier series is useful in problems on electrical circuits having impressed periodic voltage.

n takes value $0, \pm 1, \pm 2$ and so on now this is known as the complex form of all the Fourier series of f okay and its Fourier coefficients are given by 9. So, this is known as the complex form of the Fourier series of f where c_n s are given by this expression This is useful in problems on electrical circuits having impressed periodic voltage.

(Refer Slide Time: 48:31)

Example: Find the complex form of the Fourier series of

$$f(x) = e^{-x}, \quad -1 < x < 1. \quad T=2$$

$$\begin{aligned}
 c_n &= \frac{1}{T} \int_{-T/2}^{T/2} f(t) e^{-2\pi i n t / T} dt \\
 &= \frac{1}{2} \int_{-1}^1 e^{-t} e^{-2\pi i n t / 2} dt = \frac{1}{2} \int_{-1}^1 e^{-t(1 + \pi i n)} dt \\
 &= \frac{1}{2} \left[\frac{e^{-t(1 + \pi i n)}}{-(1 + \pi i n)} \right]_{-1}^1 = \frac{1}{2} \left(\frac{e^{-(1 + \pi i n)}}{-(1 + \pi i n)} + \frac{e^{-(-1 + \pi i n)}}{1 + \pi i n} \right)
 \end{aligned}$$

This complex form of the Fourier series of f so here we need to find cns c_n as we have seen earlier $1/T - T/2$ to $T/2$ and we have $f(t) e^{-2\pi i n t / T}$ okay. So, $-2\pi i n t / T$ okay let us put together now $f(t) e^{-2\pi i n t / T}$ okay. So, we get 1 over 2 from -1 to 1 $T=2$ here and $f(t) e^{-2\pi i n t / T}$ okay. So, we get here is 1 over 2 then we integrate this by parts and when you integrate and evaluate this you will get the value of c_n .

The complex form of the Fourier series is this one $n=-\infty$ to ∞ $c_n e^{2\pi i n t / T}$ so what we do is this is $n=-\infty$ to ∞ $c_n e^{2\pi i n t / T}$. So, when you integrate /parts we will get e^{-t} and $e^{-2\pi i n t / T}$. We can write it like this instead of we can join this like this $2 \int_{-1}^1 e^{-t(1 + \pi i n)} dt$ okay. So we get 2 here $/2$ okay dt.

And then we can integrate so we get here $e^{-t(1 + \pi i n)}$ okay I can $/2$ so this is $1/2$ okay when we put the limits -1 to 1 so this is $1/2$ okay when we put the limits $e^{-t(1 + \pi i n)}$ and over $-(1 + \pi i n)$ and then we get $e^{-t(1 + \pi i n)}$ and this becomes $1/2$ okay so $1/2$ okay and then we simplify this and when you simplify this you get

(Refer Slide Time: 51:43)

Then

$$e^{-x} = \sum_{n=-\infty}^{\infty} (-1)^n \frac{(1 - in\pi) \sinh 1}{(1 + n^2 \pi^2)} e^{in\pi x}.$$

The representation of e^{-x} in the complex form of the Fourier series. With this I would like to end my lecture. Thank you very much for your attention.
