Lecture - 51
Laplace Equation - III

Hello friends. Welcome to my lecture on Laplace equation. This is third lecture on Laplace equation. We will be considering Laplace equation in spherical coordinates in this lecture.

(Refer Slide Time: 00:39)

Laplace equation in spherical co-ordinates:
 Let the spherical co-ordinates be (r, θ, ϕ) , then we have
 $x = r \cos \phi \sin \theta, y = r \sin \phi \sin \theta, z = r \cos \theta$

The Laplacian of a function $u(x, y, z)$ in spherical co-ordinates is

$$\nabla^2 u = u_{rr} + \frac{2}{r} u_r + \frac{1}{r^2} u_{\theta\theta} + \frac{\cot \theta}{r^2} u_\theta + \frac{1}{r^2 \sin^2 \theta} u_{\phi\phi} = 0. \quad (1)$$

We may also write the Laplacian of u as

$$\nabla^2 u = \frac{1}{r^2} \left[\frac{\partial}{\partial r} \left(r^2 \frac{\partial u}{\partial r} \right) + \frac{1}{\sin \theta} \frac{\partial}{\partial \theta} \left(\sin \theta \frac{\partial u}{\partial \theta} \right) + \frac{1}{\sin^2 \theta} \frac{\partial^2 u}{\partial \phi^2} \right] = 0.$$

Handwritten notes on the slide:
 Diagram: A 3D coordinate system with x, y, z axes. A point P(x, y, z) is shown in spherical coordinates (r, theta, phi). The origin is O. The radial distance is r. The polar angle from the z-axis is theta. The azimuthal angle from the x-axis in the xy-plane is phi. The orthogonal projection of P on the xy-plane is P-dash. Handwritten notes include: OP = r, z = r cos theta, OP = r sin theta, z = r sin theta cos phi, r = r sin theta phi.

We know that the spherical coordinates r, theta, phi are related to the Cartesian coordinates x, y, z by the questions $x=r \cos \phi \sin \theta$, $y=r \sin \phi \sin \theta$, $z=r \cos \theta$ where theta is the polar angle, phi the azimuthal angle. You can see suppose we take this point p here whose Cartesian coordinates are x, y, z and spherical polar coordinates are r, theta phi. Then, this is your orthogonal projection p dash, we join origin to p dash.

Then, this is r, draw lines through p dash parallel to x and y axis, then this is x, this is y, so oa is x, ob is y and oz this is c okay, so this is point c, this one okay so this is your oc is z and this angle is phi because phi is the azimuthal angle, this angle is theta okay. So then what we notice is that op is r okay so op is r therefore and this z axis makes angle theta with op so $z=r \cos \theta$.

Now when this is r cos theta, oc is r cos theta, this is r sin theta so this is also r sin theta. So op dash is r sin theta and therefore the components of op dash along x and y axis are r sin

theta cos phi and r sin theta sin phi. So this is x is r sin theta cos phi and y is r sin theta sin phi and then z is r cos theta and when we find the Laplacian of a function u x, y, z in its spherical coordinates what we notice is that del square u is u rr, u rr is second order partial derivative of u with respect to r as usual okay.

This is first derivative of u with respect to r so 2/r ur 1/r square, then this is second order partial derivative of u with respect to theta. Then, cot theta/r square first order derivative of u with respect to theta, then 1/r square sin square theta u phi phi, u phi phi is second order partial of u with respect to phi. We are taking this without proof because its proof is very, very lengthy.

So we may also write the Laplacian of u. Now you can see the terms u rr+2/r ur can be expressed as 1/r square times partial derivative with respect to r of r square del u/del r and then here the 2 terms 1/r square u theta theta+cot theta/r square u theta is nothing but 1/r square times 1/sin theta partial derivative with respect to theta of sin theta first derivative of u with respect to theta.

And the last term is 1/r square sin square theta u phi phi, so this equation can also be written in this form.

(Refer Slide Time: 04:46)

Case of axial symmetry:
 Sometimes we have a problem in which the potential is the same at similarly situated points in all the planes passing through a particular axis. If we take this axis as the z-axis, then u depends only on r and theta, and does not depend on phi. In such a case, the Laplace equation (1) reduces to

$$u_{rr} + \frac{2}{r}u_r + \frac{1}{r^2}u_{\theta\theta} + \frac{\cot \theta}{r^2}u_\theta = 0.$$

$\frac{\partial^2 u}{\partial \phi^2} = 0$

3

Now we will come across several problems where the potential will be same at similarly situated planes in all the planes passing through a particular axis. So if you take that axis as z axis then you will depend only on r and theta. It will not depend on phi, so in such a case the

second order partial derivative of u with respect to phi will be 0 and therefore Laplace equation 1 will reduce to $u r r+2/r u r+1/r^2 u \theta \theta+\cot \theta / r^2 u \theta=0$.

So we will have this equation, now let us study how to solve this Laplace equation by separation of variables method.

(Refer Slide Time: 05:35)

Spherical form:
 Let $u(r, \theta, \phi) = R(r)G(\theta)H(\phi)$ be the solution of (4). Then substituting in (1) and dividing by RGH , we get

$$\frac{1}{R} \left(r^2 \frac{d^2 R}{dr^2} + 2r \frac{dR}{dr} \right) + \frac{1}{G} \left(\frac{d^2 G}{d\theta^2} + \cot \theta \frac{dG}{d\theta} \right) + \frac{1}{H \sin^2 \theta} \frac{d^2 H}{d\phi^2} = 0.$$

Let us put

$$\frac{1}{R} \left(r^2 \frac{d^2 R}{dr^2} + 2r \frac{dR}{dr} \right) = n(n+1)$$

and

$$\frac{1}{G} \left(\frac{d^2 G}{d\theta^2} + \cot \theta \frac{dG}{d\theta} \right) = -m^2,$$

and

$$\frac{1}{H} \frac{d^2 H}{d\phi^2} = -k^2,$$

Handwritten notes in red ink on the slide include:
 $\frac{d^2 H}{d\phi^2} = -k^2 H$
 $\frac{d^2 G}{d\theta^2} + \cot \theta \frac{dG}{d\theta} = -m^2 G$
 $\frac{d^2 R}{dr^2} + \frac{2}{r} \frac{dR}{dr} = \frac{n(n+1)}{r^2} R$
 $H = H(\theta, \phi)$
 $H(\theta, \phi) = H(\theta)H(\phi)$
 $\frac{d^2 H}{d\phi^2} = -k^2 H$
 $\frac{d^2 G}{d\theta^2} + \cot \theta \frac{dG}{d\theta} = -m^2 G$
 $\frac{d^2 R}{dr^2} + \frac{2}{r} \frac{dR}{dr} = \frac{n(n+1)}{r^2} R$

NPTEL ONLINE CERTIFICATION COURSE

So let us assume the solution of the equation 1 to be product of R r G theta H phi. We are using separation of variable methods, so let us take R to be a function of r only, G to be a function of theta only, H to be a function of phi only and then substitute this u r, theta, phi=RGH into the equation 1 okay. So let this be the solution of equation 1, then substituting it into 1 and dividing by RGH.

You can easily verify that what we get is $1/R r^2 d^2 R/dr^2 + 2r dR/dr + 1/G d^2 G/d\theta^2 + \cot \theta dG/d\theta + 1/H \sin^2 \theta d^2 H/d\phi^2$. Now this equation can be written as you can multiply by $\sin^2 \theta$, so when you multiply by $\sin^2 \theta$ what you get, $\sin^2 \theta * 1/R r^2 d^2 R/dr^2 + 2r dR/dr + \sin^2 \theta / G * d^2 G/d\theta^2 + \cot \theta dG/d\theta = -1/H d^2 H/d\phi^2$.

Now you can see left hand side is the function of r and theta only, right hand side is the function of only phi. So this can be possible only when both are equal to a constant. So let us take this equal to a constant say k then what we will have $d^2 H/d\phi^2 = -kH$ so we will have $d^2 H/d\phi^2 = -kH$ or we will have $d^2 H/d\phi^2 + kH = 0$.

Now the boundary conditions that are given in the case of a physical problem, we shall see that the case $k=0$ is not possible and the case $k=\mu^2$ if you take $k=\mu^2$ you get H to be let us take $k=\mu^2$ then you will get $H=A \cos \mu \phi + B \sin \mu \phi$ okay, so like what I have written here $\frac{1}{H} \frac{d^2 H}{d\phi^2} = -\mu^2$ okay, so you take k to be μ^2 then you get the solution.

And for this solution what we will need that because the potential is a single valued function okay. So $H(\phi + 2\pi)$ should be $= H(\phi)$ and therefore what we will have here I have written μ but here it is m , so this μ or you can say m must be an integer.

(Refer Slide Time: 09:17)

Then,

$$R = Ar^n + Br^{-(n+1)}$$

and

$$H = C \cos m\phi + D \sin m\phi.$$

Since $H(\phi + 2\pi) = H(\phi)$, m must be an integer.

So let us see we will have $H = \text{some constant} \cdot \cos m\phi + D \sin m\phi$, if we take this $= -m^2$ okay so then what we will have this because of $H(\phi + 2\pi) = H(\phi)$, m must be taken as an integer. Now what happens when you take this as $-m^2$ okay $\frac{1}{H} \frac{d^2 H}{d\phi^2} = -m^2$ you take $\frac{1}{R} \frac{d^2 R}{dr^2} + 2r \frac{dR}{dr} = n(n+1)$, why we take it as $n(n+1)$ it will become clear later on.

(Refer Slide Time: 10:04)

Spherical form:

Let $u(r, \theta, \phi) = R(r)G(\theta)H(\phi)$ be the solution of (4). Then substituting it in (1) and dividing by RGH , we get

$$\frac{1}{R} \left(r^2 \frac{d^2 R}{dr^2} + 2r \frac{dR}{dr} \right) + \frac{1}{G} \left(\frac{d^2 G}{d\theta^2} + \cot \theta \frac{dG}{d\theta} \right) + \frac{1}{H \sin^2 \theta} \frac{d^2 H}{d\phi^2} = 0.$$

Let us put

$$\frac{1}{R} \left(r^2 \frac{d^2 R}{dr^2} + 2r \frac{dR}{dr} \right) = n(n+1)$$

and

$$\frac{1}{G} \frac{d^2 G}{d\theta^2} + \cot \theta \frac{dG}{d\theta} = -m^2,$$

Handwritten notes on slide:
 $\frac{d^2 H}{d\phi^2} - m^2 H = 0$
 $H(\phi) = A e^{m\phi} + B e^{-m\phi}$
 $H(\phi) = C \cos(m\phi) + D \sin(m\phi)$
 $\frac{d^2 R}{dr^2} + \frac{2}{r} \frac{dR}{dr} = \frac{n(n+1)}{r^2}$
 $\frac{d^2 G}{d\theta^2} + \cot \theta \frac{dG}{d\theta} = -m^2 G$
 $\frac{d^2 H}{d\phi^2} = m^2 H$
 $\frac{d^2 R}{dr^2} + \frac{2}{r} \frac{dR}{dr} = \frac{n(n+1)}{r^2}$
 $\frac{d^2 G}{d\theta^2} + \cot \theta \frac{dG}{d\theta} = -m^2 G$
 $\frac{d^2 H}{d\phi^2} = m^2 H$

So what we will have, you will have $1/R r^2 \frac{d^2 R}{dr^2} + 2r \frac{dR}{dr}$ is $n^2 + n + 1$, so we will get $n^2 + n + 1$ okay so $n^2 + n + 1 + 1/G \frac{d^2 G}{d\theta^2} + \cot \theta \frac{dG}{d\theta} + 1/H \frac{d^2 H}{d\phi^2}$ we have written $-m^2$, so we will have $-m^2 / \sin^2 \theta = 0$ okay. So this can be written as $\frac{d^2 G}{d\theta^2} + \cot \theta \frac{dG}{d\theta} + n^2 + n + 1 - m^2 / \sin^2 \theta = 0$ which is a Legendre's equation.

So we will discuss that later on and so let us see when we write this equation $= n^2 + n + 1$ what we get, now here the point is why we are not taking it as $+m^2$ square. If you take it as $+m^2$ square then what you will get, $\frac{d^2 H}{d\phi^2} = -m^2 H = 0$, instead of $-m^2$ square if you take $+m^2$ square here then what do we will get, so the solution will be $H(\phi) = A e^{m\phi} + B e^{-m\phi}$ because the auxiliary equation will have 2 real distinct roots $+m$.

Now here because we require that $H(\phi) = H(\phi)$ okay, so this cannot be fulfilled here $H(\phi) = H(\phi)$ and therefore taking $1/H \frac{d^2 H}{d\phi^2}$ to be positive m^2 square is not appropriate. Now let us look at this equation, $1/R r^2 \frac{d^2 R}{dr^2} + 2r \frac{dR}{dr}$ so this can be expressed as $r^2 \frac{d^2 R}{dr^2} + 2r \frac{dR}{dr} = n^2 + n + 1$ okay. So let us discuss how we solve this in the next slide.

(Refer Slide Time: 12:44)

Then,

$$R = Ar^n + Br^{-(n+1)}$$

and

$$H = C \cos m\phi + D \sin m\phi.$$

Since $H(\phi + 2\pi) = H(\phi)$, m must be an integer.

Handwritten notes:

$$r^2 \frac{d^2 R}{dr^2} + 2r \frac{dR}{dr} - (n+1)nR = 0$$

Let us put $r = e^z$

$$D(D-1)R + 2DR - n(n+1)R = 0$$

$$(D^2 - D + 2D - n(n+1))R = 0$$

$$(D^2 + D - n(n+1))R = 0$$

$$m^2 + m - n(n+1) = 0$$

$$(m^2 - n^2) + (m - n) = 0$$

$$(m-n)(m+n) + (m-n) = 0$$

$$(m-n)(m+n+1) = 0$$

$$m = n, -(n+1)$$

$$R(z) = Ae^{nz} + Be^{-(n+1)z}$$

$$= Ae^{n \ln r} + Be^{-(n+1) \ln r}$$

$$\Rightarrow R(r) = Ar^n + Br^{-(n+1)}$$

So $r^2 \frac{d^2 R}{dr^2} + 2r \frac{dR}{dr} - (n+1)nR = 0$ okay, so let us put $r = e^z$ to the power z , let us change the independent variable from r to z then what we will have $r^2 \frac{d^2 R}{dr^2}$ because this is Cauchy-Euler equation. So $r^2 \frac{d^2 R}{dr^2}$ will become $D(D-1)R + 2DR - n(n+1)R = 0$ or I can write it as $D^2 - D + 2D - n(n+1)$ operating on $R = 0$ and what we get then $D^2 + D - n(n+1)R = 0$ okay.

So in order to find the solution of this, now this is a linear differential equation with constant coefficients. So we write the auxiliary equation $m^2 + m - n(n+1) = 0$ and what we can do we can write it as $m^2 - n^2 + m - n = 0$. Now $m^2 - n^2$ and then what we will get $m-n$, only $m-n$ is left okay, so this is $(m-n)(m+n)$ and we have $m-n$ here, so taking $m-n$ common we get $m+n+1$ okay.

So there are 2 roots of the auxiliary equation $m=n$ and $-n+1$, so the general solution of this equation is $R(z) = A e^{nz} + B e^{-(n+1)z}$, let us say $A e^{m_1 z} + B e^{m_2 z}$, m_1 is say n so $A e^{nz} + B e^{-(n+1)z}$. Now $e^{nz} = r^n$ okay so this implies replacing z/r we get $A r^n + B r^{-(n+1)}$. So this is how we get value of r , H we have already seen, $H = C \cos m\phi + D \sin m\phi$.

(Refer Slide Time: 15:43)

Thus we have

$$\frac{d^2G}{d\theta^2} + \cot \theta \frac{dG}{d\theta} + \left(n(n+1) - \frac{m^2}{\sin^2 \theta} \right) G = 0$$

Let us recall the Legendre's equation

$$(1-x^2)y'' - 2xy' + n(n+1)y = 0.$$

Differentiating this equation m times by Leibniz rule, we get

$$(1-x^2)y_{m+2} - 2(m+1)xy_{m+1} + (n-m)(n+m+1)y_m = 0.$$

Now, let us put $\frac{d^m y}{dx^m} = u$, then we obtain

$$(1-x^2)u'' - 2(m+1)xu' + (n-m)(n+m+1)u = 0.$$

And then the remaining expression in theta gives us this differential equation. Now this differential equation is associated Legendre's equation, we can arrive at this equation using the Legendre's equation. Legendre's equation is given by $(1-x^2)y'' - 2xy' + n(n+1)y = 0$. Let us differentiate this equation m times by using the Leibniz rule. So when you use the Leibniz rule you get $(1-x^2)y_{m+2} - 2(m+1)xy_{m+1} + (n-m)(n+m+1)y_m = 0$.

And here when you put $\frac{d^m y}{dx^m}$ that is the mth derivative of $y=u$ but you get $(1-x^2)u'' - 2(m+1)xu' + (n-m)(n+m+1)u = 0$.

(Refer Slide Time: 16:37)

Next, let us put $G = (1-x^2)^{m/2}u$ in the above equation, then we get

$$(1-x^2)G'' - 2xG' + \left\{ n(n+1) - \frac{m^2}{(1-x^2)} \right\} G = 0.$$

Now, putting $x = \cos \theta$, we get

$$\frac{d^2G}{d\theta^2} + \cot \theta \frac{dG}{d\theta} + \left(n(n+1) - \frac{m^2}{\sin^2 \theta} \right) G = 0$$

and its solution is

$$G = P_n^m(\cos \theta) + FQ_n^m(\sin \theta).$$

Multiplying R, G and H we get a solution of Laplace equation which is called as spherical harmonic.

Next, let us put $G = (1-x^2)^{m/2}u$ in the above equation. So we change from U to G okay by making the substitution in the above equation. Then, we get $(1-x^2)u'' - 2(m+1)xu' + (n-m)(n+m+1)u = 0$.

$\nabla^2 G = 0$ means $\frac{d^2 G}{dx^2} - 2x \frac{dG}{dx} + n(n+1)G = 0$.
 Now we put $x = \cos \theta$, so we change the independent variable from x to θ here and when you change the independent variable from x to θ you can verify what we get is $\frac{d^2 G}{d\theta^2} + \cot \theta \frac{dG}{d\theta} + n(n+1)G = 0$.

And this is now associated Legendre's equation, its solution is $G = P_n^m(\cos \theta) + Q_n^m(\sin \theta)$. So we have the values of R , G , and H all of them, let us multiple R , G , and H then we get a solution of Laplace equation which we call as spherical harmonic.

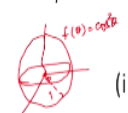

(Refer Slide Time: 17:54)

Example 1: Find the potential in the interior of a sphere of unit radius when the potential on the surface is $f(\theta) = \cos^2 \theta$.

Solution: Taking the origin at the centre of the sphere, we observe that the potential is the same at any point because it is independent of ϕ on the surface S . Hence, the Laplace equation reduces to

$$u_{rr} + \frac{2}{r}u_r + \frac{1}{r^2}u_{\theta\theta} + \frac{\cot \theta}{r^2}u_\theta = 0. \quad (i)$$

Let us put $u = R(r)G(\theta)$, then

$$\frac{1}{R} \left(r^2 \frac{d^2 R}{dr^2} + 2r \frac{dR}{dr} \right) = -\frac{1}{G} \left(\frac{d^2 G}{d\theta^2} + \cot \theta \frac{dG}{d\theta} \right) = k \text{ (a constant) .}$$

IT KOOKEE | NPTEL ONLINE CERTIFICATION COURSE | 8

Now let us discuss a problem, find the potential in the interior of a sphere of unit radius when the potential on the surface is $\cos^2 \theta$. So if you take the surface the center of the sphere at the origin okay let us take the center of the sphere as the origin okay we observe that here $f(\theta) = \cos^2 \theta$. The radius is unity okay, so we observe that the potential is same at any point because it is independent of ϕ okay on the surface.

On the surface, $f(\theta)$ is $\cos^2 \theta$, the potential is $\cos^2 \theta$, so the potential u will not depend on ϕ , hence the Laplace equation reduces to $u_{rr} + \frac{2}{r}u_r + \frac{1}{r^2}u_{\theta\theta} + \frac{\cot \theta}{r^2}u_\theta = 0$. Now we have to find solution of this equation. So let us take u to be a function of r and θ , so $u = R(r)G(\theta)$, you put it in this equation what we will get is $\frac{1}{R} \left(r^2 \frac{d^2 R}{dr^2} + 2r \frac{dR}{dr} \right) = -\frac{1}{G} \left(\frac{d^2 G}{d\theta^2} + \cot \theta \frac{dG}{d\theta} \right)$.

Now this quantity on the left depends on R the independent variable R only, the right hand side depends on theta only, both are equal so they must be equal to a constant. So they are equal to a constant let us say k okay.

(Refer Slide Time: 19:39)

Taking, $k = n(n + 1)$, we get

$$\frac{d^2 G}{d\theta^2} + \cot \theta \frac{dG}{d\theta} + n(n + 1)G = 0 \quad \text{(ii)}$$

and

$$r^2 \frac{d^2 R}{dr^2} + 2r \frac{dR}{dr} - n(n + 1)R = 0 \quad \text{(iii)}$$

Putting $\cos \theta = v$ in (ii), we get

$$(1 - v^2) \frac{d^2 G}{dv^2} - 2v \frac{dG}{dv} + n(n + 1)G = 0$$

which is a Legendre's equation. Its solutions are $G = P_n(\cos \theta)$, $n = 0, 1, 2, \dots$

The solution of (iii) is $R = \left(Ar^n + \frac{B}{r^{n+1}} \right)$

IIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 9

Let us take $k=n^2+n+1$, by taking $k=n^2+n+1$ we know the equation this one $r^2 \frac{d^2 R}{dr^2} + 2r \frac{dR}{dr} - n^2 - n + 1 R = 0$ is a Cauchy-Euler equation whose solution we know that its solution is $Ar^n + \frac{B}{r^{n+1}}$. So that is the solution of this equation 3 we have already discussed and $\frac{d^2 G}{d\theta^2} + \cot \theta \frac{dG}{d\theta} + n^2 - n + 1 G = 0$ which we get the other equation that we get here okay.

That changes to this equation if you put $\cos \theta = v$ in this okay. So taking $\cos \theta = v$ this equation changes to so we are changing the independent variable from theta to v now. So $(1 - v^2) \frac{d^2 G}{dv^2} - 2v \frac{dG}{dv} + n^2 - n + 1 G = 0$ which is the Legendre equation okay. So which is the Legendre equation, its solutions are the Legendre polynomials $P_n(\cos \theta)$ where n takes values 0, 1, 2 and so on.

(Refer Slide Time: 20:55)

We therefore obtain

$$u(r, \theta) = \left(Ar^n + \frac{B}{r^{n+1}} \right) P_n(\cos \theta), \quad n = 0, 1, 2, \dots$$

For the solution to be finite at $r=0$, we must take $B=0$ and thus

$$u(r, \theta) = \sum_{n=0}^{\infty} A_n r^n P_n(\cos \theta),$$

On the boundary of the sphere, $u(1, \theta) = f(\theta) = \cos^2 \theta$

$$\cos^2 \theta = \sum_{n=0}^{\infty} A_n P_n(\cos \theta)$$

which is Fourier Legendre expansion of $\cos^2 \theta$. Hence

So we can obtain therefore the expression for $u(r, \theta)$, $u(r, \theta)$ is $r^n \cdot G(\theta)$ so Ar^n to the power $n+B/r$ to the power $n+1$ $P_n(\cos \theta)$ where $n=0, 1, 2$ and so on. Now because our region includes the origin $r=0$, r is 0 at the center of the sphere, so we want the solution to be finite and when we want u to be finite at $r=0$ we must take $B=0$ otherwise B is not 0 this u cannot be finite at $r=0$.

So we must take $B=0$ and therefore we have $u(r, \theta) = \sum_{n=0}^{\infty} A_n r^n P_n(\cos \theta)$. Now on the boundary of the sphere, we are given the potential to be $F(\theta)$ that is $\cos^2 \theta$. So taking $r=1$ in this equation what we get, $\cos^2 \theta = \sum_{n=0}^{\infty} A_n P_n(\cos \theta)$, which is Fourier Legendre expansion of $\cos^2 \theta$.

And we know that in the case of a Fourier Legendre expansion of a function $F(\theta)$ what we get is this formula.

(Refer Slide Time: 22:09)

Hence,
$$A_n = \left(n + \frac{1}{2}\right) \int_{-1}^1 f(x) P_n(x) dx, \quad \text{where } x = \cos \theta$$

$$= \left(n + \frac{1}{2}\right) \int_{-1}^1 x^2 P_n(x) dx$$

$$= \left(n + \frac{1}{2}\right) \int_{-1}^1 \left(\frac{2}{3} P_2(x) + \frac{1}{3} P_0(x)\right) P_n(x) dx$$

Using the orthogonality property of Legendre polynomials, we get $A_n = 0$, for all n except $n=0$ and 2 .

Handwritten notes:
 $f(x) = x^2 = \cos^2 \theta$ when $x = \cos \theta$
 $P_0(x) = 1$
 $P_2(x) = \frac{1}{2}(3x^2 - 1)$
 $x^2 = \frac{2P_2(x) + 1}{3}$
 $A_0 = \frac{1}{2} \cdot \frac{1}{3} \int_{-1}^1 P_0^2(x) dx = \frac{1}{2} \cdot \frac{1}{3} \cdot 2 = \frac{1}{3}$
 $A_2 = \frac{5}{2} \cdot \frac{1}{3} \int_{-1}^1 P_2^2(x) dx = \frac{5}{2} \cdot \frac{1}{3} \cdot \frac{2}{5} = \frac{1}{3}$
 $\int_{-1}^1 P_n(x) P_m(x) dx = \begin{cases} 0, & m \neq n \\ \frac{2}{2n+1}, & m=n \end{cases}$

IT KOOKEE | NPTEL ONLINE CERTIFICATION COURSE | 11

So constants A_n can be computed by the formula $n+1/2 \int_{-1}^1 f(x) P_n(x) dx$ where x is $\cos \theta$. Now we are given that on the boundary of θ is $\cos^2 \theta$ okay, so $f(x)$ is equal to now here $f(x)$ is what $f(x)$ becomes $\cos^2 \theta$ when $x = \cos \theta$ okay. So I should write $f(x)$ becomes $\cos^2 \theta$ let me write $f(x) = x^2$ okay so what I mean is that on the boundary the temperature is $\cos^2 \theta$.

So $f(x)$ becomes x^2 because when your $f(x)$ is x^2 $f(\cos \theta)$ becomes $\cos^2 \theta$. So $f(x)$ gives $\cos^2 \theta$ when $x = \cos \theta$ so this is x^2 actually, $f(x) = x^2$ which is $\cos^2 \theta$ okay. So $f(x) = x^2$ gives $\cos^2 \theta$ when x is $\cos \theta$. So this formula actually is for here we have $f(x)$ here okay and we have $\sum_{n=0}^{\infty} A_n P_n(x)$. So it is the formula for that, now here in place of x we have $\cos \theta$ so we need to write the corresponding formula in terms of x .

So $n+1/2 \int_{-1}^1 x^2 P_n(x) dx$ and now what we do we remember that in the case of Legendre polynomials p and x , $p_0(x) = 1$ while $p_2(x)$ is $1/2 * 3x^2 - 1$. So we can express x^2 as $2/3 p_2(x) + 1/3 p_0(x)$ or we can write it as $2/3 p_2(x) + 1/3 p_0(x)$. So x^2 will be replaced by $2/3 P_2(x) + 1/3 P_0(x) * P_n(x)$. Now let us recall the orthogonality property of Legendre polynomials.

The orthogonality property is that $\int_{-1}^1 P_n(x) P_m(x) dx = 0$ whenever $m \neq n$ okay and this is $2/(2n+1)$ when $m=n$ okay. So applying that what will happen $\int_{-1}^1 P_n(x) P_2(x) dx$ will be 0 for all n other than 2 okay. So when $n=2$ integral over -1 to 1 $P_2(x) P_2(x) dx$ that is $P_2^2(x)$,

$P_2 x^2$ can be computed from here, it will be $\frac{2}{\sqrt{5}}$ okay and similarly -1 to 1 $P_0 x^n$ will be 0 for all $n \neq 0$.

And when $n=0$ we will have -1 to 1 P_0^2 and P_0^2 will be $\frac{2}{1}$ so it will be 2 okay. So using the orthogonality property of Legendre polynomials we get $A_n=0$ for all n except $n=0$ and 2. So let us find A_0 okay. We can find A_0 here. $A_0 = \frac{1}{2} \int_{-1}^1 P_0^2 dx$ so $\frac{1}{2}$ we are taking $n=0$, $n=0$ means we will have $\frac{1}{3} \int_{-1}^1 P_0^2 dx$. So this will be $\frac{1}{2} \cdot \frac{1}{3} \int_{-1}^1 P_0^2 dx = 2$ okay.

So we get $\frac{1}{3}$ and A_2 we can similarly find, A_2 will be $\frac{2}{\sqrt{5}}$ so $\frac{2}{\sqrt{5}} \int_{-1}^1 P_2^2 dx$, so this will be $\frac{2}{\sqrt{5}} \cdot \frac{2}{5} \int_{-1}^1 P_2^2 dx = \frac{2}{3}$. So we know the values of A_0 and A_2 and so we can write the expression for $u(r, \theta)$.

(Refer Slide Time: 27:00)

Now $A_0 = \frac{1}{3}, A_2 = \frac{2}{3}$.

Thus,

$$u(r, \theta) = \frac{1}{3} P_0(\cos \theta) + \frac{2}{3} r^2 P_2(\cos \theta) = \frac{1}{3} + r^2 \left(\cos^2 \theta - \frac{1}{3} \right),$$

in view of

$$P_0(x) = 1, P_2(x) = \frac{1}{2}(3x^2 - 1)$$

IT KOOKEE NPTEL ONLINE CERTIFICATION COURSE 12

So what will happen, we have $A_0=1/3, A_2=2/3$, $u(r, \theta)$ will then be $A_0 r^0 + A_2 r^2 P_2(\cos \theta)$ okay.

(Refer Slide Time: 27:15)

We therefore obtain

$$u(r, \theta) = \left(Ar^n + \frac{B}{r^{n+1}} \right) P_n(\cos \theta), \quad n = 0, 1, 2, \dots$$

For the solution to be finite at $r=0$, we must take $B=0$ and thus

$$u(r, \theta) = \sum_{n=0}^{\infty} A_n r^n P_n(\cos \theta), \quad u(r, \theta) = A_0 r^0 P_0(\cos \theta) + A_2 r^2 P_2(\cos \theta)$$

On the boundary of the sphere, $u(1, \theta) = f(\theta) = \cos^2 \theta = \frac{1}{3} P_0(\cos \theta) + \frac{2}{3} r^2 P_2(\cos \theta)$

$$\cos^2 \theta = \sum_{n=0}^{\infty} A_n P_n(\cos \theta)$$

which is Fourier Legendre expansion of $\cos^2 \theta$. Hence

We will have $u(r, \theta) = A_n r^n$ is 0 for all n except $n=0$ and 2 so we have $A_0 r^0 \cos \theta + A_2 r^2 P_2(\cos \theta)$. We have found $A_0=1/3$, $A_2=2/3$. So this will be $1/3 P_0 \cos \theta + 2/3 r^2 P_2 \cos \theta$ okay.

(Refer Slide Time: 27:59)

Now $A_0 = \frac{1}{3}, A_2 = \frac{2}{3}$.

Thus,

$$u(r, \theta) = \frac{1}{3} P_0(\cos \theta) + \frac{2}{3} r^2 P_2(\cos \theta) = \frac{1}{3} + r^2 \left(\cos^2 \theta - \frac{1}{3} \right),$$

in view of

$$P_0(x) = 1, P_2(x) = \frac{1}{2}(3x^2 - 1)$$

Handwritten notes:
 $P_0(x) = 1$
 $P_0(\cos \theta) = 1$
 $P_2(x) = \frac{1}{2}(3x^2 - 1)$
 $P_2(\cos \theta) = \frac{1}{2}(3\cos^2 \theta - 1)$

$$u(r, \theta) = \frac{1}{3} + \frac{2}{3} r^2 \left(\frac{3}{2} \cos^2 \theta - \frac{1}{2} \right)$$

$$= \frac{1}{3} + r^2 \cos^2 \theta - \frac{1}{3} r^2$$

$$= \frac{1}{3} + r^2 \left(\cos^2 \theta - \frac{1}{3} \right)$$

So let us go there we have $1/3 P_0 \cos \theta + 2/3 r^2 P_2 \cos \theta$ okay. Now we know $P_0(x)=1$ okay, so $P_0 \cos \theta$ is also 1, $P_0 \cos \theta$ is 1 and then we know $P_2(x)=1/2(3x^2-1)$, so $P_2 \cos \theta$ will be $1/2(3 \cos^2 \theta - 1)$. So let us put these values, so $u(r, \theta)$ will be $1/3 P_0 \cos \theta + 2/3 r^2 P_2 \cos \theta$ is $1/3 + 2/3 r^2 (1/2(3 \cos^2 \theta - 1))$. So what do we get $1/3 + r^2 \cos^2 \theta - 1/3 r^2$ if we multiple $2/3$ will cancel with $3/2$ we get $r^2 \cos^2 \theta$.

And then $\frac{2}{3}r^2$ we multiply to $-\frac{1}{2}$ so what do we get $\frac{2}{3}r^2$ will cancel will get $-\frac{1}{3}r^2$ square. So we get $\frac{1}{3}r^2 \cos^2 \theta - \frac{1}{3}$ okay in view of $P_0 x=1, P_2 x=1/2$ $3x^2-1$. So this is the solution to the given problem.

(Refer Slide Time: 29:47)

Example1: Find the gravitational potential of a uniform disc of mass M and radius a at any external point.

Solution: Let us take the centre of the disc as the origin and the normal there as the z -axis. Then, due to symmetry, the potential u at a point $P(r, \theta, \phi)$ will depend on r and θ only.

Hence, we have to solve the equation

$$u_{rr} + \frac{2}{r}u_r + \frac{1}{r^2}u_{\theta\theta} + \frac{\cot \theta}{r^2}u_{\theta} = 0.$$

Let us put $u(r, \theta) = R(r)G(\theta)$ then the solution of Laplace equation appropriate to the problem is

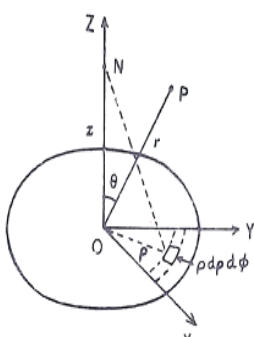

$$u(r, \theta) = \sum_{n=0}^{\infty} \left(A_n r^n + \frac{B_n}{r^{n+1}} \right) P_n(\cos \theta). \quad (iv)$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 13

Now let us find the gravitational potential of a uniform disc of mass M and radius a at any external point. So let us take the center of the disc as the origin and the normal there as the z -axis.

(Refer Slide Time: 30:03)

In order to obtain the coefficients A_n and B_n , let us obtain the potential of the disc at a point N on the Z -axis.

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 14

Let us look at this is the figure okay, so this is the disc and this is the center of the disc and this x is normal x line at the point is the z -axis. By symmetry the potential u at any point P r, θ, ϕ will depend on r and θ only because of the symmetry of the disc. So hence we

have to solve the equation $u_{rr} + \frac{2}{r}u_r + \frac{1}{r^2}u_{\theta\theta} + \cot\theta \frac{u}{r} = 0$.
 Again let us put $u(r, \theta) = R(r)G(\theta)$.

Then, the solution of the Laplace equation appropriate to the problem is given by $u(r, \theta) = \sum_{n=0}^{\infty} A_n r^n + B_n/r^{n+1} P_n(\cos\theta)$. Now in order to obtain the values of A_n and B_n let us obtain the potential of the disc at a point n on the z -axis. So for this what we do is we take a small element here at a distance ρ from the center and making this angle is let us say this element $\rho d\rho d\phi$ okay.

(Refer Slide Time: 31:19)

From the figure, the potential of an element $\rho d\rho d\phi$ of the disc at N

$$= \frac{GM}{\pi a^2} (\rho d\rho d\phi) \frac{1}{\sqrt{(z^2 + \rho^2)}}$$

Hence, the potential of the whole disc

$$= \frac{GM}{\pi a^2} \int_0^{2\pi} \int_0^a \frac{\rho d\rho d\phi}{\sqrt{(z^2 + \rho^2)}} = \frac{2GM}{a^2} \left[\sqrt{(z^2 + a^2)} - z \right]$$

IT KOOKEE | NPTEL ONLINE CERTIFICATION COURSE | 15

$\rho d\rho d\phi$ we take and then for this element what we will have the potential of an element $\rho, d\rho, d\phi$ of the disc at n at the point n okay will be $= GM/\pi a^2 \rho d\rho d\phi / \sqrt{z^2 + \rho^2}$, $\sqrt{z^2 + \rho^2}$ is the distance of the point okay this distance okay this distance is $\sqrt{z^2 + \rho^2}$ so we have $1/\sqrt{z^2 + \rho^2}$ because we know that potential is GMm/r okay.

So this is actually r or r is under $\sqrt{z^2 + \rho^2}$ and this gives you GMm/r so hence the potential of the whole disc is $GM/\pi a^2 \int_0^{2\pi} \int_0^a \rho d\rho d\phi / \sqrt{z^2 + \rho^2}$. Now this we can easily integrate and when you integrate what we get is $2GM/a^2 \left[\sqrt{z^2 + a^2} - z \right]$ okay.

(Refer Slide Time: 32:32)

When $z > a$, we have

$$\frac{2GM}{a^2} \left[z \left(1 + \frac{a^2}{z^2} \right)^{1/2} - z \right]$$

$$= \frac{2GM}{a^2} \left[\frac{1}{2} \frac{a^2}{z} - \frac{1}{2.4} \frac{a^4}{z^3} + \frac{1.3}{2.4.6} \frac{a^6}{z^5} - \dots \right] \quad (v)$$

On the Z-axis at N , $\theta=0$ and $r=z$ hence (iv) reduces to

$$u(r, \theta) = \sum_{n=0}^{\infty} \left(A_n z^n + \frac{B_n}{z^{n+1}} \right). \quad (vi)$$

16

Now what we have when z is $>a$, we have $2GM/a^2$ square $z \cdot 1 + a^2/z^2$ to the power $1/2$ z okay. Here we are integrating with respect to ρ okay yeah. So what we have let us look at this. This expression under root $z^2 + a^2$ if $z >a$ can be written as $z \sqrt{1 + a^2/z^2}$ and $1 + a^2/z^2$ to the power $1/2$ then we can write its binomial expansion and we get $2GM/a^2$ $1/2 a^2/z - 1/2 \cdot 1/4 a^4/z^3 + 1 \cdot 3/2 \cdot 1/4 \cdot 6 a^6/z^5 - \dots$ to the power $6/z$ to the power 5 and so on.

On the z -axis at the point n okay let us look at the figure at the point n $\theta=0$ and $z=r$ so $r=z$ okay this distance this is r okay which is z . So what we will have, so this solution reduces to $A_n z^n$ to the power n becomes r^n becomes z^n , B_n/z^{n+1} to the power $n+1$ and θ is 0 so P_n is always 1 and so $u(r, \theta)$ becomes this. Now comparing 5th and 6th, let us compare 5th and 6th, when you compare you see that $B_n=0$ when n is odd okay.

Because we have only odd powers of $1/z$ here in this expression okay. In this infinite series, only odd powers of z are present so when n is odd okay then $n+1$ will be even. So $B_n=0$ when n is odd okay, A_n is 0 for all n because there is no term in positive integral powers of z , so $A_n=0$ for all n and $B_n=0$ when n is odd okay.

(Refer Slide Time: 34:55)

Now, comparing (v) and (vi) we obtain

$$A_n = 0, \forall n \text{ and } B_n = 0, \text{ when } n \text{ is odd}$$

and

$$B_0 = GM, B_2 = -\frac{GMa^2}{4}, B_4 = \frac{1.3}{4.6} GMa^4$$

Hence for $r > a$,

$$u(r, \theta) = \frac{GM}{r} \left[1 - \frac{1}{4} \frac{a^2}{r^2} P_2(\cos \theta) + \frac{1.3}{4.6} \frac{a^4}{r^4} P_4(\cos \theta) - \dots \right]$$

o

 IIT KOOBKE
  NPTEL ONLINE CERTIFICATION COURSE
 17

And we can write the values of B0, B2, B4 from here by comparison okay. So we have B0 this, B2 this, B4 this and therefore for $r > a$ okay $r > a$ u r, theta is=this one u r, theta=GM/r 1- 1/4 a square/ r square P2 cos theta we can put the values of B0, B2, B4 in this expression okay.

(Refer Slide Time: 35:26)

Similarly, for $z < a$,

$$\frac{2GM}{a^2} \left((z^2 + a^2)^{1/2} - z \right) = \frac{2GM}{a^2} \left[a - z + \frac{1}{2} \frac{z^2}{a} - \frac{1}{2.4} \frac{z^4}{a^3} + \dots \right]$$

Again, comparing this with (vi), we get

$$B_n = 0, \forall n$$

$$A_0 = \frac{2GM}{a}, A_1 = -\frac{2GM}{a^2}, A_2 = \frac{GM}{a^3}, \dots$$

Hence the solution for $r < a$ is

$$u(r, \theta) = \frac{GM}{a} \left[2 - \frac{2r}{a} P_1(\cos \theta) + \frac{r^2}{a^2} P_2(\cos \theta) - \frac{1}{4} \frac{r^4}{a^4} P_4(\cos \theta) \dots \right]$$

 IIT KOOBKE
  NPTEL ONLINE CERTIFICATION COURSE
 18

Now when we have $z < a$ okay, when we have $z < a$ that is n is at a distance less than a from the center of this sphere then we will have $2GM/a$ square. Again look at this expression, $2GM/a$ square under root z square+a square-z so this time $z < a$ so we shall write a we will take outside the square root so a under root $1+z$ square/a square we shall consider. So a times under root $1+z$ square/a square, z/a is < 1 so we can again expand it to binomial expansion arrive here.

Again compare this with the equation 5 this equation okay because we are getting this expression at the point n . Now here what is happening is you can see we have $A_0 = A_0$ is the coefficient of z to the power 0. So A_0 is present there but A_1, A_2, A_3 they are all 0s because the positive integral powers of z are absent in that expression okay. So we have positive integral powers are there, negative integral powers are not there.

So $B_n = 0$ for all n , A_0 is $2GM/a$ A_1 is $-2GM/a$ square, A_2 is GM/a cube and so on so the solution for $r < a$ is $u(r, \theta) =$ this. So with this I would like to end my lecture. Thank you very much for your attention.
