Lecture – 54
One Dimensional Wave Equations and its Solutions- II

Hello friends, welcome to this lecture, in this lecture, we will continue a study of wave equation and if you recall in previous lecture, we have discussed the one-dimension wave equation and we discussed the D'Alembert's solution for one-dimension wave equation and now we continue our study from that onward. So, we have discussed the string problem infinite length and the solution is known as D'Alembert's solution.

(Refer Slide Time: 01:03)

Semi-infinite string

✱

Now consider the motion of a semi- infinite string $x \geq 0$ having one end fixed at the point $x = 0$. The conditions (10) are now given as follows

$$u = F(x), \frac{\partial u}{\partial t} = G(x), x \geq 0 \text{ at } t = 0 \quad (14a)$$

$$u = 0, \frac{\partial u}{\partial t} = 0, t \geq 0 \text{ at } x = 0. \quad (14b)$$

Here, we can not apply the D'Alembert solution directly as the expression $F(x - ct)$ will be meaningless if $t > x/c$ so solution (12) will not be applicable.

$$u(x,t) = \frac{1}{2} [F(x+ct) + F(x-ct)] + \frac{1}{2c} \int_{x-ct}^{x+ct} G(\xi) d\xi$$

Now, let us move semi-infinite string, so it means that now consider the motion of a semi-infinite string, so here x is lying between 0 to infinity, so $x \geq 0$ having one end fixed at the point $x = 0$, so it is like this, you have this point and from here, it is already fixed, so at $x = 0$, your string is fixed at point $x = 0$. Now, the condition; initial and boundary condition are given like this that the initial shape is given as $u = F$ of x and initial velocity $\frac{du}{dt}$ given as G of x at $x \geq 0$ at $t = 0$.

So, initial displacement and initial velocity is given by this and since one end is fixed at the $x = 0$, so here we will introduce boundary condition as well, so here at $x = 0$, your u is $= 0$ and $\frac{du}{dt}$

double t is also 0, so at this fixed point, the displacement as well as the velocity is 0, so at $t \geq 0$ and $x = 0$, so here this is fixed, so your position as well as velocity will remain 0 for all time $t \geq 0$ and if you look at here, we cannot apply the D'Alembert's solution directly.

Because if you remember your solution will be what; $u(x,t) = \frac{1}{2} [F(x+ct) + F(x-ct)] + \frac{1}{2c} \int_{x-ct}^{x+ct} G(\xi) d\xi$, and the problem is that here your F of x is defined for $x \geq 0$, so it means that argument of a F is positive only but and here if we take $x - ct$, now if $x - ct < 0$, then this will not be defined, so it means that I cannot use the solution; D'Alembert's solution for this semi-infinite string right now.

So, what we trying to see here; so let us modify our problem in a bit such that I can apply this D'Alembert's solution for this semi-infinite string also, so what we try to do; we extend our this part, the other half part in a way such that this problem; the consider problem is a particular part of this extended problem.

(Refer Slide Time: 03:28)

Suppose, we consider an infinite string subject to the initial conditions

$$u = Y(x), \quad \frac{\partial u}{\partial t} = V(x) \quad \text{at } t = 0,$$

where

$$Y(x) = \begin{cases} F(x), & x \geq 0; \\ -F(-x), & x < 0. \end{cases}$$

And

$$V(x) = \begin{cases} G(x), & x \geq 0; \\ -G(-x), & x < 0. \end{cases}$$

Then its displacement is given by

$$u = \frac{1}{2} \{ Y(x+ct) + Y(x-ct) \} + \frac{1}{2c} \int_{x-ct}^{x+ct} V(\xi) d\xi \quad (15)$$

So, here what we do, suppose we consider an infinite string subject to the initial condition. so, let us say that consider an infinite string where displacement is given as Y of x, initial velocity is given as V of x at $t = 0$, so here since it is an infinite string let us say that your Y of x is given as F of x as $x \geq 0$, so this is matching with your condition, which is already given as for this semi-infinite string problem.

So, Y of x is $= F$ of x , when $x \geq 0$, now we are extending finding these Y of x as a odd extension of this function F of x , so Y of $x = -$ of $F -x$, when x is < 0 , so it means that when is < 0 , so $-x$ is positive, so $-$ of F of $-x$ is defined here, so we can say that here Y of x is an odd extension of this function F of x . Similarly, we can extend our function g of x in odd manner for the entire $-\infty$ to ∞ and we defined V of $x = G$ of x for $x > 0$ minus.

And $-$ of $G -$ of x , when x is < 0 , so now once we define your y_x and v_x for the entire infinite region, so it means that then I can apply D'Alembert's solution for this infinite string and our solution is given as $u = 1/2 y$ of $x + ct + y$ of $x - ct + 1$ upon $2c x - ct$ to $x + ct V \xi d \xi$, now our claim is that with the expression Y and V given as follows, this will act as a solution of the semi-infinite problem also.

(Refer Slide Time: 05:29)

so that when $x = 0$

$$u = \frac{1}{2} \{ Y(ct) + Y(-ct) \} + \frac{1}{2c} \int_{-ct}^{ct} V(\xi) d\xi \quad (16)$$

and

$$\frac{\partial u}{\partial t} = \frac{1}{2} c \{ Y'(ct) - Y'(-ct) \} + \frac{1}{2} \{ V(ct) + V(-ct) \}$$

From the definitions of Y and V , both these functions are identically zero for all values of t and therefore the function (16) satisfies the condition (14b) as well as the differential equation (8) and also satisfies the condition (14a).

$Y(-x) = -Y(x)$
 $-Y'(-x) = -Y'(x)$

So, we need to see it will satisfy all the initial and boundary conditions that we have to look at here. So, here look at; at $x = 0$, so at $x = 0$, your u_{xt} will be what; $u_{xt} = 1$ upon $2 Y$ of $ct + Y$ of $-ct + 1$ upon $2c - ct$ to $ct V \xi d \xi$ and $\frac{\partial u}{\partial t}$ you can calculate $1/2c y$ dash $ct - y$ dash $-ct + 1/2 V ct + V$ of $-ct$. Now, as we have defined the function Y as odd function it means that Y of $-x$ is $-$ of Y of x , so this quality will be 0.

Similarly, V_{xi} is also defined in an odd manner, so it means that this integral is going to be your 0, similarly you can say that this $y \text{ dash } ct - y \text{ dash } -ct$ here, I am assuming that $Y \text{ of } -x = - \text{ of } Y \text{ of } x$, so when you differentiated your, what you will get? $Y \text{ dash of } -x, -1$ here = - of $Y \text{ of } x$; $Y \text{ dash } x$. So, using this, this quantity is 0 and this quantity is 0, so it means that $u_{xt}; u_0; t$ is going to be 0 and $\text{dou } u / \text{dou } t$ at $x = 0$ is going to be 0.

And also that if you look at your solution, which is defined as 15, it will also satisfy the initial condition that is $u \text{ of } xt \text{ is } = F \text{ of } x; u \text{ of } x0 = F \text{ of } x$ for $x \geq 0$, so it will also satisfy the initial condition as well as the initial velocity here. So, it means that the solution given by this equation number 15 will satisfy all the initial condition and the boundary condition given at $x = 0$ and so we can take the solution given in 15 as the solution of semi-infinite problem.

(Refer Slide Time: 07:39)

In particular, if string is released from rest so that initial velocity G , and hence, V , is identically zero, we find the corresponding solution is

$$u = \begin{cases} \frac{1}{2}[F(x+ct) + F(x-ct)], & x \geq ct; \\ \frac{1}{2}[F(x+ct) - F(x-ct)], & x \leq ct. \end{cases}$$

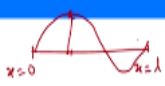

And in this way our D'Alembert's solution is still applicable for semi-infinite problem as well, now in particular if a string is released from rest, so that initial velocity G is taken a 0 and if initial velocity G is 0, so V is also coming to be 0 and your solution u is defined as $1/2 F \text{ of } x + ct + F \text{ of } x - ct$, when $x \geq$ or $= ct$, so argument $x - ct$ is positive, $x + ct$ is positive, so I can define u_{xt} as this.

But when $x <$ or $= ct$ then I can define as $F \text{ of } x + ct - F \text{ of } x - ct$, so here this is the small change you can say from the infinite string problem to semi-infinite problem. Now, let us move

to finite string, so what we have done? We have considered at first the infinite string and we obtained a solution which is known as D'Alembert's solution and then we consider a semi-infinite problem.

(Refer Slide Time: 08:49)

Finite String

In case of finite string of length l lying along the x -axis, $0 \leq x \leq l$, then initial conditions can be modified in the form

$$u = F(x), \quad \frac{\partial u}{\partial t} = G(x), \quad 0 \leq x \leq l \quad \text{at } t = 0,$$

$$u = 0, \quad \frac{\partial u}{\partial t} = 0, \quad t \geq 0 \quad \text{at } x = 0 \text{ and } x = l.$$

$u(0,t) = 0$
 $u(l,t) = 0$

and by similar method to the one above, it can be easily shown that the solution of the wave equation (8) satisfying these conditions is the expression (15),

It means that a string is fixed at one end and then we modify our solution of infinite string to get a solution for semi-infinite string, now let us do the similar thing for finite string case, so in case of finite string of length l , lying along the x axis where x is between 0 to l , so here, your string is now clamped at 2 and say it is $x = 0$ and $x = l$. So, here now you we want to see the vibration in this string, so here suppose initial condition is given as $u = F$ of x .

So, it means that initial shape is something like this, so this will represent the at this point your displacement from the initial condition is F of x , so at any point if you look at you can find out the displacement, let us say that initial displacement is given by $u = F$ of x and initial velocity is given by G of x and it is true for all x lying between 0 to l and $t = 0$, so initial displacement and initial velocity is given.

Now, since we assume that both the end are fixed line, right now for this particular problem, so it means that $u(0,t) = 0$ and $u(l,t) = 0$, so it means that $u(0,t) = 0$ and $u(l,t) = 0$ here, so it means that because here we assume that your ends point are fixed here, now we want to find out the solution for this finite string problem and we try to see that the solution obtained

for infinite string can be modified in a way that we can obtain a solution for this finite string as well.

(Refer Slide Time: 10:31)

where the function $Y(x)$ is defined by the relation

$$Y(x) = \begin{cases} F(x), & 0 \leq x \leq l; \\ -F(-x), & -l \leq x \leq 0. \end{cases}$$

$Y(x + 2rl) = Y(x)$ if $-l \leq x \leq l$ and $r = \pm 1, \pm 2, \dots$

i.e. $Y(x)$ is an odd periodic function of period $2l$ and the Fourier sine expression of such an odd function is

$$Y(x) = \sum_{m=0}^{\infty} F_m \sin\left(\frac{m\pi x}{l}\right)$$

$$Y(x + 2rl) = Y(x) \quad (17)$$

$$V(x) = \begin{cases} G(x) & 0 \leq x \leq l \\ -G(-x) & -l \leq x \leq 0 \end{cases}$$

Handwritten notes:
 $Y(x) \sin\left(\frac{m\pi x}{l}\right) dx = \int_0^l F_m \sin^2\left(\frac{m\pi x}{l}\right) dx$
 $\int_{-l}^l Y(x) \sin\left(\frac{m\pi x}{l}\right) dx = 2 \int_0^l F_m \sin^2\left(\frac{m\pi x}{l}\right) dx$

So, here we; as we discuss for semi-infinite string, let us modify our function Y of x as F of x lying between 0 to l and $-$ of F of $-x$ between $-l$ to 0 , so what we try to do here; we write it $-l$ to this l , so here your function is something some function is given, so at 0 , it is 0 only, so here some function is given. Now, you define in an odd manner, such that here you will get the similar thing here.

So, you define Y as a odd function; odd extension of F of x in $-l$ to 0 also, so it means that now Yx is defined between $-l$ to l and Y of x is $= F$ of x in 0 to l and Y of x is $= -$ of F of $-x$ lying between $-l$ to 0 . Now then, you since it is given only for $-l$ to l , then you use periodicity to; extend it to entire $-\infty$ to ∞ , so let us assume the periodicity as Y of $x + 2rl = Y$ of x , where x is lying between $-l$ to l and r is your integer values $+ -1$ and $+ -2$ and so on.

So, Yx is an odd periodic function of period $2l$ and the Fourier sin expression of such an odd function, you can find out like Y of $x = \sum_{m=0}^{\infty} F_m \sin\left(\frac{m\pi x}{l}\right)$. Similarly, you can define your V of x as follows, let us say G of x , $0 < x < l$ and $-$ of G of $-x$ $-l < x < 0$ and here also you can consider the corresponding $Vx + 2rl = V$ of x , where x is lying between $-l$ to l and r is $+ -1 + -2$.

(Refer Slide Time: 12:31)

where the coefficients F_m are given by the formula

$$F_m = \frac{2}{l} \int_0^l F(\xi) \sin\left(\frac{m\pi\xi}{l}\right) d\xi \quad (18)$$

Similarly,

$$V(x) = \sum_{m=1}^{\infty} G_m \sin\left(\frac{m\pi x}{l}\right) \quad (19)$$

where

$$G_m = \frac{2}{l} \int_0^l G(\xi) \sin\left(\frac{m\pi\xi}{l}\right) d\xi \quad (20)$$

And similarly, as Y is having a Fourier sine expression, similarly you can define the Fourier sine expression for V of x also and we can say that sorry; V of x can be written as $m = 1$ to infinity $G_m \sin m \pi x / l$ and here, the Fourier coefficient that is F of m and G of m, you can find out using orthogonality property of sin and cosine functions, so sin function here. So, here if you remember here, what is the solution here; yx is given by this.

So, if I want to find out F_m , then what you will do? You just multiply by $\sin m \pi x / l$ by, so you you have Y of x $\sin n \pi x / l$ d of x and you integrate between the 0 to; -l to l, right and see what you will get here, it is summation $m = 0$ to infinity F of m $\sin m \pi x / l * 0$ to l and then here you will get with in product \sin of $n \pi x / l$, d of x and then use of orthogonality property of $\sin n \pi x / l$ and you will see that your F of m you can obtain by this.

(Refer Slide Time: 14:14)

Substituting the results, we get

$$\frac{1}{2} \{ Y(x+ct) + Y(x-ct) \} = \sum_{m=0}^{\infty} F_m \sin\left(\frac{m\pi x}{l}\right) \cos\left(\frac{m\pi ct}{l}\right) \quad \checkmark$$

$$\checkmark \frac{1}{2c} \int_{x-ct}^{x+ct} V(\xi) d\xi = \frac{l}{\pi c} \sum_{m=0}^{\infty} \frac{G_m}{m} \sin\left(\frac{m\pi x}{l}\right) \sin\left(\frac{m\pi ct}{l}\right)$$

which follow from these expressions, into the solution (15), the solution of the present problem is

$$u = \sum_{m=1}^{\infty} \underbrace{F_m}_{\text{red}} \sin\left(\frac{m\pi x}{l}\right) \cos\left(\frac{m\pi ct}{l}\right) + \frac{l}{\pi c} \sum_{m=1}^{\infty} \underbrace{\frac{G_m}{m}}_{\text{red}} \sin\left(\frac{m\pi x}{l}\right) \sin\left(\frac{m\pi ct}{l}\right)$$

where F_m and G_m are defined by equations (18) and (20) respectively.

It is $\frac{1}{2} \int_0^l F(x) \sin \frac{m\pi x}{l} dx$, similarly you can obtain G_m that is $\frac{1}{2} \int_0^l G(x) \sin \frac{m\pi x}{l} dx$ and if you look at both Y and V are similar to each other in fact, it is kind of symmetry, so once we have the expression for Y and V , we can write, we can substitute our relation, so here our solution $\frac{1}{2} Y(x+ct) + Y(x-ct)$, you can write it $m = 0$ to infinity $F_m \sin \frac{m\pi x}{l} \cos \frac{m\pi ct}{l}$.

So, here we simply use expression $Y(x)$ as this and when you have this then you can write $Y(x+ct)$ and 0 to infinity $m = 0$ to infinity $F_m \sin \frac{m\pi x - x + ct}{l}$, similarly you can write $Y(x-ct)$ and then you simplify, then you can use $\sin(a+b) + \sin(a-b)$ formula and you can get the formula; series expression like this, so we have this part, we have this part, so we can write down our solution $u(x,t)$ as $m = 1$ to 1 to infinity $F_m \sin \frac{m\pi x}{l} \cos \frac{m\pi ct}{l}$.

This is corresponding to $\frac{1}{2} Y(x+ct) + Y(x-ct)$ and then corresponding to integral part, $\frac{1}{2c} \int_{x-ct}^{x+ct} V(\xi) d\xi$, we can write down this expression and we have this, so we can write $u(x,t)$ as $m = 1$ to infinity $F_m \sin \frac{m\pi x}{l} \cos \frac{m\pi ct}{l} + \frac{l}{\pi c} \sum_{m=1}^{\infty} \frac{G_m}{m} \sin \frac{m\pi x}{l} \sin \frac{m\pi ct}{l}$ and here the coefficient F_m and G_m , you can obtain using the expression 18 and this 20.

(Refer Slide Time: 16:13)

Vibrating strings- variables separable solution

Consider a thin homogeneous string which is perfectly flexible under uniform tension lie in its equilibrium position along the x - axis. The ends of strings are fixed at $x = 0$ and $x = L$.

The string is pulled aside a short distance and released. If no external forces are present which corresponds to the case of free vibrations, the subsequent motion of the string is described by the solution $u(x, t)$ of the following problem:

So, it means that solution is given as this, so now we have obtained this solution using D'Alembert's solution for infinite string and we modify our problem in a way such that we can utilise this D'Alembert's solution for finite string as well. Now, let us look at the same problem and now you try to find out the solution using variable and separable method. So, here we consider a thin homogeneous string which is perfectly flexible under uniform tension lie in the equilibrium position along the x axis.

The ends of a string are fix at $x = 0$ and $x = L$ that lying in it at $x = 0$ here and $x = l$ here, the string is pulled aside a short distance, so once we have this thing then you simply pull along one side, then it is something like this kind of figure and released and if no external forces are present which correspond to the case of free vibrations, so it means that here once we put it like this and then we simply leave.

So, it means that no other force we; say, apply after that, so it means that at initial position, it is simply left, then we try to find out the vibration of this string and the subsequent motion of the string is described by the solution $u(x, t)$ of the following problem.

(Refer Slide Time: 17:40)

PDE:

$$u_{tt} - c^2 u_{xx} = 0, \quad 0 \leq x \leq L, \quad t > 0 \quad (21)$$

Boundary conditions:

$$\begin{array}{l} u(0, t) = 0, t > 0 \\ u(L, t) = 0, t > 0 \end{array} \quad (22)$$

Initial conditions:

$$u(x, 0) = f(x), u_t(x, 0) = g(x) \quad (23)$$

The following problem is this, it is PDE $u_{tt} - c^2 u_{xx} = 0$, x is lying between 0 to L , t is > 0 and boundary conditions are what; if you look at we have taken the end fixed, so $x = 0$ $u(0, t) = 0$ and $x = L$ $u(L, t) = 0$ and initial condition is given as $u(x, 0) = f(x)$ then $u_t(x, 0) = g(x)$, so here we consider the same problem but now we try to solve in a different manner using separation and variable method.

(Refer Slide Time: 18:17)

To obtain the variables separable solution, we assume

$$u(x, t) = X(x)T(t) \quad (24)$$

and substituting into equation (21), we obtain

$$X \frac{d^2 T}{dt^2} = c^2 T \frac{d^2 X}{dx^2}$$

i.e.

$$\frac{X \frac{d^2 T}{dt^2}}{c^2 T} = \frac{d^2 X}{dx^2} = k \quad (\text{a separation constant})$$

So, to obtain the variable separable solution, we assume that $u(x, t) = X(x)T(t)$, now here, please remember here that you cannot apply your variable separable method for any problem, here you need to have your problem separable as well as the boundary separable, so it means that you

have to choose your coordinate system in a such that your equation is separable as well as the boundary is also separable.

We will see that here both the equation as well as the boundary condition are separable to each other, so let us see what I mean. So, here if you put $u(x,t) = X(x)T(t)$, then your solution is what? It is your problem is what; $u_{tt} = c^2 u_{xx}$ then you will write $T''(x) = c^2 X''(x)T(x)$ divide by $X(x)T(x)$, so you will get $T''(x)/T(x) = c^2 X''(x)/X(x)$ that is what it is written here.

So, $X \frac{d^2 T}{dt^2} = c^2 T \frac{d^2 X}{dx^2}$ and then you divide by $c^2 XT$ and we have this equation that $\frac{d^2 T}{dt^2} \div c^2 T = \frac{d^2 X}{dx^2} \div X = k$ here.

(Refer Slide Time: 19:46)

Case I When $k > 0$, we have $k = \lambda^2$. Then

$$\left. \begin{aligned} \frac{d^2 X}{dx^2} - \lambda^2 X &= 0 \\ \frac{d^2 T}{dt^2} - c^2 \lambda^2 T &= 0 \end{aligned} \right\} \checkmark$$

Their solution can be put in the form

$$X(x) = c_1 e^{\lambda x} + c_2 e^{-\lambda x} \quad (25)$$

$$T(t) = c_3 e^{c\lambda t} + c_4 e^{-c\lambda t} \quad (26)$$

Therefore,

$$u(x,t) = (c_1 e^{\lambda x} + c_2 e^{-\lambda x})(c_3 e^{c\lambda t} + c_4 e^{-c\lambda t}) \quad (27)$$

Now, here this k is a separation constant, so it means that we can write our equation like this, $\frac{d^2 X}{dx^2} - \lambda^2 X = 0$ and $\frac{d^2 T}{dt^2} - c^2 \lambda^2 T = 0$. Now, here let us consider 3 cases for these constants here; so, k let us assume that k is positive, negative and 0 and we try to find out the nontrivial solution in each cases, so here basically it is a Eigen value problem, system value problem.

And we have already discuss the similar system value problem, when we discuss the boundary value problem, so now we can find out the solution of these problems as X of $x = c_1 e$ to the power $\lambda x + c_2 e$ to the power $-\lambda x$ and similarly, you can write down t as $c_3 e$ to the power $c \lambda t + c_4 e$ to the power $c \lambda t$, so now our solution $u(x,t)$ is written as $c_1 e$ to the power $\lambda x + c_2 e$ to the power $-\lambda x * c_3 e$ to the power $c \lambda t + c_4 e$ to the power $-c \lambda t$ here.

(Refer Slide Time: 21:02)

Now, using the boundary conditions, we have

$$u(0, t) = 0 = (c_1 + c_2)(c_3 e^{c\lambda t} + c_4 e^{-c\lambda t}) \quad (28)$$

which implies that $c_1 + c_2 = 0$. Also, $u(L, t) = 0$ gives

$$c_1 e^{\lambda L} + c_2 e^{-\lambda L} = 0$$

$$\begin{aligned} u(0, t) = 0 & \quad X(0)T(t) = 0 \\ u(L, t) = 0 & \quad X(L)T(t) = 0 \\ X(0) = 0 & \\ X(L) = 0 & \end{aligned}$$

$$\begin{aligned} X(x) &= c_1 e^{\lambda x} + c_2 e^{-\lambda x} \\ 0 &= c_1 + c_2 \\ 0 &= c_1 e^{\lambda L} + c_2 e^{-\lambda L} \quad (29) \end{aligned}$$

$$\begin{bmatrix} 1 & 1 \\ e^{\lambda L} & e^{-\lambda L} \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$c_1 = 0 = c_2$

Now, we have to obtain 4 constants; $C_1 C_2 C_3 C_4$, so here we will use the boundary condition, so boundary conditions are what? It is $u(0, t) = 0$ and $u(L, t) = 0$, so when you put your solution this X of 0 , T of $t = 0$ and similarly X of L , T of $t = 0$ here, so here since T of t cannot be identically $= 0$, so this implies that X of 0 is $= 0$ and X of L is $= 0$, so using this you can solve this problem, your X of x is what; X of x is $= c_1 e$ to the power $\lambda x + c_2 e$ to the power $-\lambda x$.

So, it is $c_1 e$ to the power $\lambda x + c_2 e$ to the power $-\lambda x$, so use $X(0) = 0$, so what you will get? It is $0 = c_1 + c_2$ and $X(L)$, it means this is $0 = c_1 e$ to the power $\lambda L + c_2 e$ to the power $-\lambda L$. Then, you want to find out c_1, c_2 , so c_1, c_2 , you can find out using this matrix equation, this is $0 = 0$ and you can get here $1 \ 1$ and e to the power λL and e to the power $-\lambda L$ and if you see that this determinant is non-zero, so we can say that here I will get only a trivial solution that is $c_1 = c_2 = 0$.

(Refer Slide Time: 22:20)

Equations (28) and (29) possess a non-trivial solution iff

$$\delta = \begin{vmatrix} 1 & 1 \\ e^{\lambda L} & e^{-\lambda L} \end{vmatrix} = e^{-\lambda L} - e^{\lambda L} = 0$$

Since $L \neq 0$ so $e^{-\lambda L} - e^{\lambda L} = 0$ implies that $\lambda = 0$ which is against the assumption as in Case I. Hence, solution is not acceptable.

So, it means that in this case, we will have only a trivial solution, so if since this value is a nonzero implies that lambda has to be 0, so this value determinant has to have value 0 provided u lambda is = 0 but lambda; we have assumed that lambda is nonzero because here we have assumed that k is > 0 here, so it means that lambda cannot be 0 but this determinant is having 0 value when lambda is = 0.

So, it means that it is against our assumption in this case, so hence our solution is non-acceptable means, your; in this case when k is positive, we will not get any nontrivial solution, so here what we have seen here that in case when k is positive, we do not have any nontrivial solution.

(Refer Slide Time: 23:26)

Case II Let $k = 0$. Then we have

$$\frac{d^2 X}{dx^2} = 0, \frac{d^2 T}{dt^2} = 0$$

Corresponding solutions are:

$$X(x) = Ax + B, T(t) = ct + D$$

Therefore, the required solution of the PDE (21) is

$$u(x, t) = (Ax + B)(ct + D)$$

Using the boundary conditions, we have $u(0, t) = 0 = B(ct + D)$ implying $B = 0$

$u(L, t) = 0 = AL(ct + D)$ implying $A = 0$

Hence, only trivial solution is possible.

So, now let us consider next case that is let $k = 0$ here and in this case our equation is reduced to $d^2X/dx^2 = 0$ and $d^2T/dt^2 = 0$ and in this case you can find out your solution as X of $x = Ax + B$ and T of $t = ct + D$, again as we have pointed out the solution $u(x,t)$ is written as $Ax + B + ct + D$ here.

(Refer Slide Time: 23:58)

$$\begin{aligned}
 & x(0) = 0 = x(l) \\
 & X(x) = Ax + B \\
 & 0 = B \qquad 0 = Al \\
 & \qquad \qquad \underline{A = 0} \\
 & X(x) \equiv 0 \\
 & X(x) = c_1 \cos \lambda x + c_2 \sin \lambda x \\
 & X(0) = 0 = c_1 \\
 & X(l) = 0 = \underline{c_2 \sin \lambda l} \\
 & \lambda l = n\pi \\
 & \lambda = \frac{n\pi}{l}, \quad n = \pm 1, \pm 2, \dots
 \end{aligned}$$

Now, our initial condition is what; initial condition we have seen that it is same; x of $0 = 0 = x$ of l , so our solution is X of $x =$ say, $Ax + B$ here, so put $x_0 = 0$, so this implies that $B = 0$ and then when you put $x_l = 0$, then it is $Al = 0$ and since l is nonzero, so this implies that $A = 0$, so here this X of x is coming out to be identically $= 0$. So, in this case using the boundary condition we have $u_0 t = 0 + B + ct + D$ implies that $B = 0$ and similarly, we can say that $A = 0$.

(Refer Slide Time: 24:49)

Case III When $k < 0$, say $k = -\lambda^2$, the differential equations are

$$\frac{d^2 X}{dx^2} + \lambda^2 X = 0$$

$$\frac{d^2 T}{dt^2} + c^2 \lambda^2 T = 0$$

Their general solution give

$$u(x, t) = (c_1 \cos \lambda x + c_2 \sin \lambda x)(c_3 \cos c \lambda t + c_4 \sin c \lambda t) \quad (30)$$

So, here also this part is completely 0, so it means that $u(x, t)$ is only a 0 solution, so it means that when $k = 0$ also, then we do not have any nontrivial solution, so this case is also, we will leave. Now, let us consider the third case that is $k < 0$, so in this case let us assumed that $k = -\lambda^2$ and the corresponding differential equation is $\frac{d^2 X}{dx^2} + \lambda^2 X = 0$ and $\frac{d^2 T}{dt^2} + c^2 \lambda^2 T = 0$.

So, here general solution is given as corresponding to this general solution is $C_1 \cos \lambda x + C_2 \sin \lambda x$ and corresponding to this, we have $C_3 \cos c \lambda t + C_4 \sin c \lambda t$ is given, now you try to fix your C_1 and C_2 and you can see that how we can fix this C_1 and C_2 , so here let us say we have a problem $C_1 \cos \lambda x + C_2 \sin \lambda x$ and that is your X of x , so let us put term X of $0 = 0$ that implies that your C_1 has to be 0.

(Refer Slide Time: 26:26)

Using the boundary conditions: $u(0, t) = 0$, we obtain $c_1 = 0$. Using the boundary conditions: $u(L, t) = 0$, we obtain $\sin \lambda L = 0$ implying that $\lambda_n = n\pi/L$, $n = 1, 2, \dots$, which are the eigenvalues. Hence the possible solution is

$$u_n(x, t) = \sin \frac{n\pi x}{L} \left(A_n \cos \frac{n\pi ct}{L} + B_n \sin \frac{n\pi ct}{L} \right), n = 1, 2, \dots \quad (31)$$

Using the superposition principle, we have

$$u(x, t) = \sum_{n=1}^{\infty} \sin \frac{n\pi x}{L} \left(A_n \cos \frac{n\pi ct}{L} + B_n \sin \frac{n\pi ct}{L} \right) \quad (32)$$

Then $X(0) = 0$ implies that $C_2 \sin(\lambda \cdot 0) = 0$ and if we take this C_2 is 0, then we will again get a trivial solution, so we want that this λ to be chosen like here $n\pi$ so, let us say λ is $= n\pi/L$, where n is taking as $+1, -2$ and so on, so it means that if we take λ as $n\pi/L$, then we will get a nontrivial solution, so it means that let us see this implies that here you will get a nontrivial solution provided this λ is $n\pi/L$, which is given here that using the boundary condition $u(0, t) = 0$, we get $c_1 = 0$ as we have pointed out.

And using the boundary condition, $u(L, t) = 0$, we have $\sin \lambda L = 0$, this implies that λ is written as $n\pi/L$, where n is 1, 2, 3 and any integer value, which are the eigenvalues corresponding to the Eigen function $\sin \lambda x$. So, here you can write down the solution as $u(x, t) = \sin \frac{n\pi x}{L} \left(A_n \cos \frac{n\pi ct}{L} + B_n \sin \frac{n\pi ct}{L} \right)$, here I am using the value λ as $n\pi/L$ in this case here, you use C_1 is 0, so this is gone.

And here $\sin \frac{n\pi x}{L}$ is there, you just replace the value of λ and since this is true for every n , so we can write down for every n , we can write down the solution $u(x, t)$ as $\sin \frac{n\pi x}{L} \left(A_n \cos \frac{n\pi ct}{L} + B_n \sin \frac{n\pi ct}{L} \right)$, now since for each n , we have a solution then of the homogeneous problem, then you should take this summation from $n = 1$ to infinity, then also it will remain the solution of this homogeneous problem.

So, using; this is known as superposition principle that if we have a homogeneous problem and we have v_1 and v_2 as 2 solutions, then linear combination of v_1 and v_2 will also be a solution of the homogeneous problem and this is known as a superposition principle, so using superposition principle we can write down our solution as $u(x,t) = \sum_{n=1}^{\infty} \sin \frac{n\pi x}{L} [A_n \cos \frac{n\pi ct}{L} + B_n \sin \frac{n\pi ct}{L}]$.

(Refer Slide Time: 28:19)

The initial conditions give

$$u(x, 0) = f(x) = \sum_{n=1}^{\infty} A_n \sin \frac{n\pi x}{L}$$

which is a half-range Fourier sine series, where

$$A_n = \frac{2}{L} \int_0^L f(x) \sin \frac{n\pi x}{L} dx \quad (33)$$

Now, here your coefficient A_n and B_n is still unknown, so to find out the coefficient of A_n and B_n , we will use our initial condition that is $u(x,0) = f(x)$, when you put $t=0$, then this part is gone, so you will get $A_n \cos \frac{n\pi ct}{L}$ is going to be 1, so we will get $u(x,0) = \sum_{n=1}^{\infty} A_n \sin \frac{n\pi x}{L}$, so that is what we have written; $u(x,0) = \sum_{n=1}^{\infty} A_n \sin \frac{n\pi x}{L}$ and we already know the value of $u(x,0)$ that is given as $f(x)$.

(Refer Slide Time: 29:00)

$$\begin{aligned}
 f(x) &= \sum A_n \sin\left(\frac{n\pi x}{L}\right) \\
 \int_0^L \left(\sin\frac{m\pi x}{L}\right) f(x) dx &= \int_0^L \left(\sum A_n \sin\frac{n\pi x}{L}\right) \sin\left(\frac{m\pi x}{L}\right) dx \\
 &= \sum_{n=1}^{\infty} A_n \int_0^L \sin\frac{n\pi x}{L} \sin\frac{m\pi x}{L} dx \\
 \int_0^L \sin\frac{m\pi x}{L} dx &= A_m \left(\frac{L}{2}\right)
 \end{aligned}$$

So, now with the help of this we try to find out the value of A_n , so how to find out value of A_n , so here you just multiply the $\sin m \pi x/L$, so let us consider this problem, so here we have your f of $x = \text{summation } A_n \sin n \pi x/L$, so multiply both side by say, $\sin \sin m \pi x/L * F$ of x dx and integrate between 0 to L here, which is given as summation integrate between 0 to L $A_n \sin n \pi x/L * \sin m \pi x/L$ and dx and we say that this I can write as summation A_n assuming that this infinite series is uniformly convergent.

So, we can write it here $n = 1$ to infinity $A_n \int_0^L \sin n \pi x/L \sin m \pi x/L dx$ of here, so using the orthogonality, we say that m is $\neq n$, then this value is $= 0$ and when m is $= n$ or you can say the value A_n , this n is $= m$ then this value is coming out to be $L/2$, so we can write the value $A_m L/2 = \int_0^L f(x) \sin m \pi x/L dx$, so in this case we can find out the coefficient A_m has $2/L \int_0^L f(x) \sin m \pi x/L dx$, so that is what we have written here $A_n = 2/L \int_0^L f(x) \sin n \pi x/L dx$.

(Refer Slide Time: 30:53)

Also,

$$u_t(x, 0) = g(x) = \sum_{n=1}^{\infty} B_n \sin \frac{n\pi x}{L} \left(\frac{n\pi c}{L} \right)$$

which is also a half-range Fourier sine series, where

$$B_n = \frac{2}{n\pi c} \int_0^L g(x) \sin \frac{n\pi x}{L} dx \quad (34)$$

Hence the required solution is obtained from equation (32), where A_n and B_n are given by equations (33) and (34). $u_n(x, t)$ given by equation (31) are called normal modes of vibration and $\omega_n = n\pi L/c$, $n = 1, 2, \dots$ are called normal frequencies.

Similarly, using the next condition that is $u(x, 0) = g(x)$ and that you can get it from $n = 1$ to infinity $B_n \sin n\pi x/L * n\pi c/L$, so that we have obtained from this equation, you differentiate with respect to t and put $t = 0$, you will get this relation that $u_t(x, 0) = \sum_{n=1}^{\infty} B_n \sin n\pi x/L * n\pi c/L$, now this value is given as $g(x)$, again using the orthogonality property we can write B_n as $2/n\pi c \int_0^L g(x) \sin n\pi x/L dx$.

So, here we required the solution as obtained by say this equation number 32 that is $u(x, t) = \sum_{n=1}^{\infty} \left[A_n \cos n\pi ct/L + B_n \sin n\pi ct/L \right] \sin n\pi x/L$ and the coefficient A_n and B_n is obtained in the equation number 33 and equation number 34, so it means that once we have A_n , B_n given to us, then we can write down the solution for this finite string problem as equation number 32 I think, 32.

(Refer Slide Time: 32:11)

Uniqueness of the solution for the wave equation

As we have developed the variables separable method to find the solution to the wave equation with certain initial and boundary conditions. In this part, we shall show that the solution of one dimensional wave equation with finite domain is unique.

And here the $u_n(x,t)$ is given by equation 31 are called normal modes of vibration and the corresponding frequency $\omega_n = n\pi L/c$ are called normal frequency. Then, the next result is uniqueness of the solution for the wave equation, so as we have discussed the variables separable method to find the solution to the wave equation with certain initial and boundary condition for say, finite boundary value problem.

So, it means that in a finite string which is say, fix at the end $x = 0$ and $x = n$, we have found out the solution using variable separable method but if you remember we have also discussed the same problem and we found the solution using D'Alembert's solution of string and we came to know that both are coming as same. So, now how it is coming and so here in this particular part, we prove that the solution of one-dimension wave equation with finite domain is a unique solution.

So, it means that whether I will use D'Alembert's solution or say, variable separable method, our solution is coming to be unique, so it is up to you whether you will choose D'Alembert's solution or say, this variable separable method, the solution is coming to be same here.

(Refer Slide Time: 33:35)

Uniqueness Theorem.

The solution to the wave equation

$$u_{tt} = c^2 u_{xx} + F(x, t), \quad 0 < x < L, \quad t > 0 \quad (35)$$

satisfying the initial conditions:

$$u(x, 0) = f(x), \quad 0 \leq x \leq L$$

$$u_t(x, 0) = g(x), \quad 0 \leq x \leq L$$

and the boundary conditions:

$$u(0, t) = f_1(t), \quad u(L, t) = f_2(t),$$

where $u(x, t)$ is twice continuously differentiable function with respect to x and t , is unique.

So, let us do this problem, so this is a uniqueness theorem; the solution to the wave equation, $u_{tt} = c^2 u_{xx} + f$ of xt , here x is lying between 0 to L , $t > 0$ satisfying the initial condition that is $u(x, 0) = f$ of x ; x is lying between 0 to L , $u_t(x, 0) = g$ of x ; $0, x$ lying between 0 to L and boundary condition $u(0, t) = f_1(t)$, $u(L, t) = f_2(t)$, where $u(x, t)$ is a twice continuously differential function with respect to x and t is unique.

Now, here you note down certain things that here we are writing this function F of xt , it means that we are also considering the external force, it means that it is not say, this string is not left; say, at initial position f of x having initial displacement F of x and initial velocity is g of x but for every x and t we are also applying an external force which is given as f of xt and also that here your end points are not fixed in fact, end points are given as $f_1(t)$ and $f_2(t)$.

It means that the endpoints are not fixed in fact, that is also depending on some functions, say $f_1(t)$, $f_2(t)$ so at t is increasing, your initial point; initial displacement is also the endpoint is also moving kind of thing, so it is a moving end point problem and we say that if it is a; if it has a solution that solution must be unique, now the case which we have discuss earlier is a special case of this by assuming that f of xt is 0 and $f_1(t)$ and $f_2(t)$ are 0 .

(Refer Slide Time: 35:28)

Proof. Suppose u_1 and u_2 are two solutions of the given wave equation (35) and let $v = u_1 - u_2$. Then $v(x, t)$ is the solution of the following problem:

$$v_{tt} = c^2 v_{xx}, \quad 0 < x < L, \quad t > 0 \quad (36)$$

$$v(x, 0) = 0, \quad 0 \leq x \leq L$$

$$v_t(x, 0) = 0, \quad 0 \leq x \leq L$$

and

$$v(0, t) = v(L, t) = 0.$$

We have to prove that $v(x, t) \equiv 0$. Consider the function

$$E(t) = \frac{1}{2} \int_0^L (c^2 v_x^2 + v_t^2) dx \quad (37)$$

which represents the total energy of the vibrating string at time t .

So, it means that it is a special case of this uniqueness theorem, so if this problem has a unique solution the special case will also have a unique solution, so now let us try to prove this result, so here, suppose u_1 and u_2 are 2 solutions of the given wave equation 35 and satisfying these initial and boundary conditions. Then suppose that we have 2 solutions and now we want to show that these 2 solutions are identically same.

So, let us assume that $v = u_1 - u_2$, then this function v is a solution of the following problem; $v_{tt} = c^2 v_{xx}$, x is lying between 0 to L , t is > 0 , $v(x, 0) = 0$, $v_t(x, 0) = 0$ and $v(0, t)$ and $v(L, t)$ is coming out to be 0, so it means that if you look at here our problem is what?

(Refer Slide Time: 36:05)

Handwritten notes showing the derivation of the wave equation for $v = u_1 - u_2$ and the proof that $v = 0$ using the energy method.

$$u_{tt} = c^2 u_{xx} + F(x, t)$$

$$u(x, 0) = f(x) \quad u(x, t) = b_1(t)$$

$$u_t(x, 0) = g(x) \quad u_t(x, t) = b_2(t)$$

$$u_1 - u_2$$

$$u(x, 0) = 0$$

$$u_t(x, 0) = \lim_{h \rightarrow 0} \frac{u(x, 0+h) - u(x, 0)}{h}$$

$$u(0, t) = 0 \quad \forall t$$

$$u_t(0, t) = \lim_{h \rightarrow 0} \frac{u(0, t+h) - u(0, t)}{h}$$

$$= \lim_{h \rightarrow 0} \frac{0 - 0}{h} = 0$$

Our problem is $u_{tt} = c^2 u_{xx} + f(x,t)$ and $u(x,0)$ is going to $f(x)$; $u_t(x,0) = g(x)$ and $u(0,t) = f_1(t)$ and $u(L,t) = f_2(t)$. So, now you let us say, u_1 and u_2 are 2 solutions, so it means that you u_1 will satisfy the same equation and u_2 will also satisfy the same equation, then when you look at the $u_1 - u_2$, then this part will be cancel out, this part will also cancel out because it is independent of $u_1 * u_2$.

So, it means that now you can write it here that the corresponding solution satisfy by $u_1 - u_2$ will not have this part, this part, this part and this part, it means that the corresponding difference; $u_1 - u_2$ will satisfy the homogeneous problem like $v_{tt} = c^2 v_{xx}$ and the homogeneous initial and boundary condition. Now, we want to show that here your v_{xt} is identically $= 0$ and to prove that here, we consider the function $E_T = \frac{1}{2} \int_0^L c^2 v_x^2 + v_t^2 dx$.

Now, we want to show that how we show that v_{xt} is 0; by showing that its partial derivative $\frac{\partial}{\partial t} v_{xt}$ and how we can show that partial derivative $\frac{\partial}{\partial x} v_{xt}$, here we show that this function E_T is coming, v_0 , so it means that if this function which is known as generalised energy function. If generalised energy function is 0, it means that your string is lying in an equilibrium position that is the idea which we have started.

That if we do not have energy, then we like to be in equilibrium position, so here let us say that $E_T = \frac{1}{2} \int_0^L c^2 v_x^2 + v_t^2 dx$ and which represent the total energy of the vibrating string at time t .

(Refer Slide Time: 38:09)

Differentiating both sides of (37), we get

$$\frac{dE}{dt} = \int_0^L (c^2 v_x v_{xt} + v_t v_{tt}) dx \quad (38)$$

Integrating by parts, the right-hand side of the above equation gives us

$$\int_0^L c^2 v_x v_{xt} dx = [c^2 v_x v_t]_0^L - \int_0^L c^2 v_t v_{xx} dx$$

Now, $v(0, t) = 0$ implies $v_t(0, t) = 0$ for $t \geq 0$ and $v(L, t) = 0$ implies $v_t(L, t) = 0$ for $t \geq 0$. Hence, equation (38) reduces to

$$\frac{dE}{dt} = \int_0^L v_t (v_{tt} - c^2 v_{xx}) dx = 0$$

Now, differentiating both sides of 37, with respect to t , so $dE/dt = 0$ to L , now here when you differentiate c square v_x square, so it is $2v_x v_{xt}$ and here it is $2v_t v_{tt}$, so we will write it here as 0 to L c square $v_x v_{xt} + v_t v_{tt} dx$, now integrating by part; this part with respect to say, dx . So, when we have 0 to L C square $v_x v_{xt} dx$, this we write first indication of second, so we will get c Square $v_x v_t$ between 0 to $L - 0$ to L c square v_t and v_{xx} .

So, here indicating this thing and differentiating this, so we will get 0 to L c Square $v_t v_{xx} dx$, now if you look at this boundary term; c square $v_x v_t$ lying between 0 to L and our claim is that it is 0 , how we can show, since v is 0 t is 0 , so it means that if v is 0 , t is 0 , then v_t t is also 0 , why? So, here if you look at v_t is 0 , means what; v_0 t is $= 0$ for all t , so it means that if you want to calculate v_t t , then it is what limit?

Say, S tending to 0 , v of 0 , $t + h - v$ of $0t$ divided by h , now since it is true for all t , so this implies that limit s tending to 0 , this value is also 0 , this is already 0 , so it is nothing but 0 , so v_t t is coming out to be 0 , so here v_t t is 0 and since v_{tt} is $= 0$, since in a same manner, we can say v_t lt_0 is also 0 , so it means that this boundary term is gone, is that okay, so it means that our equation number 38 is reduced to $d/dt = 0$ to L .

In place of 1, we are writing here -0 to L c square $v_{tt} v_{xx}$, so if we take out this v_t term out because here we have $v_t v_x$ and here it is $v_t v_{tt}$, so we can write v_t times $v_{tt} - c$ square v_{xx} . Now,

if you look at; v is a solution of homogeneous problem, it means that $v_{tt} - c^2 v_{xx}$ has to be 0, so it means that since v is a solution of homogeneous problem, this dE/dt is coming out to be 0, so it means that E is constant with respect to time t .

(Refer Slide Time: 40:40)

Hence,

$$E(t) = \text{constant} = c \text{ (say)}.$$

Since $v(x, 0) = 0$ implies $v_x(x, 0) = 0$ and $v_t(x, 0) = 0$, we can evaluate c and find that

$$E(0) = c = \int_0^L \left[c^2 v_x^2 + v_t^2 \right]_{t=0} dx = 0$$

which gives $E(t) = 0$, which is possible if and only if $v_x = 0$ and $v_t = 0$ for all $t > 0$, $0 \leq x \leq L$, which is possible if and only if $v(x, t) = \text{constant}$.

However, since $v(x, 0) = 0$, we find $v(x, t) = 0$. Hence,

$$u_1(x, t) = u_2(x, t).$$

This shows that the solution of the wave equation is unique.

So, here E is constant, let us say constant value is c , now if E is constant and we already know that if $v_x = 0$, so $v_{xx} = 0$. in a similar manner we can prove that if $v_x = 0$ for all x , then the derivative of v_x with respect to x is again 0, so this also we can see like this. If $v_x = 0$, this imply we want to find out v_x of x is 0 that is limit say h tending to 0, v of $x + h$, $0 - v$ of x , 0 divided by h , now this is 0, this is 0.

So, it is coming out to be 0, so it means that $v_{xx} = 0$, $v_t = 0$, so we can calculate E of 0; E of 0 will be what? E of 0 is = what; 0 to L $c^2 v_x^2$ and v_t^2 so when you do this your this value is coming out to be 0, this value is coming out to be 0 and hence, E of 0 is coming out to be 0, but since E is constant, so it means that this constant value is coming out to be 0.

So, it means that E is 0, for all t , it means that this is possible only when the integrand; integrand is what? Integrand is $c^2 v_x^2$ and v_t^2 , these are 0 because integrand is nonnegative value, so it means that $v_x = 0$, $v_t = 0$, so it means that $v_t = 0$ and $v_x = 0$ for all $t > 0$ and if partial

derivative are 0, so it means that we say that it is possible only when v_{xt} is constant with respect to x as well as with respect to t .

So, it means that v_{xt} is constant but we already know that v_{x0} is 0, so it means that this constant value has to be 0, so it means that v_{xt} is 0 for all x and for all t , so it means that if v_{xt} is = 0 0 means, v_{xt} is what; difference of 2 solutions; it means that difference of 2 solution is identically = 0. So, it means that u and x_t is = $u^2 x_t$, so this shows that the solution of the wave equation for finite domain is unique.

So, whether you apply the separable variable method or say, D'Alembert's wave solution method both are coming out to be same, so with this I end our lecture and we will continue our lecture in next lecture, so thank you for listening us, thank you very much.
