**Lecture – 07**  
**Linear System**

Hello friends, I welcome you to my course on ordinary and partial differential equations and applications, in this course, in this lecture we shall discuss linear systems of ordinary differential equations.

**(Refer Slide Time: 00:45)**

One of the most important concepts of analysis is that of a system of  $n$  simultaneous first order differential equations in several variables i.e. equations of the form

$$\begin{aligned}\frac{dx_1}{dt} &= f_1(t, x_1, x_2, \dots, x_n) \\ \frac{dx_2}{dt} &= f_2(t, x_1, x_2, \dots, x_n) \\ &\vdots \\ \frac{dx_n}{dt} &= f_n(t, x_1, x_2, \dots, x_n)\end{aligned}\quad \dots(1)$$

---

One of the most important concepts of analysis is that of a system of  $n$  simultaneous first order differential equations in several variables, such a system can be expressed as  $dx_1/dt = f_1(t, x_1, x_2, \dots, x_n)$ ,  $dx_2/dt = f_2(t, x_1, x_2, \dots, x_n)$  and so on, the  $n$ th equation is  $dx_n/dt = f_n(t, x_1, x_2, \dots, x_n)$ . Here,  $t$  is the independent variable  $x_1, x_2, \dots, x_n$  are  $n$  dependent variables of the independent variable  $t$ .

**(Refer Slide Time: 01:22)**

where  $x_1, x_2, \dots, x_n$  are unknown functions of a single independent variable  $t$ .

Systems of differential equations arise quite naturally in many scientific problems.

A solution of system (1) is  $n$  functions  $x_1(t), x_2(t), \dots, x_n(t)$  such that

$$\frac{dx_j(t)}{dt} = f_j(t, x_1(t), x_2(t), \dots, x_n(t)), \quad j=1, 2, \dots, n$$

For example, let  $x_1(t) = t$  and  $x_2(t) = t^2$ , then we provide a solution of the simultaneous first order differential equations

$$\frac{dx_1}{dt} = 1 \quad \text{and} \quad \frac{dx_2}{dt} = 2x_1$$

Since,

$$\frac{dx_1}{dt} = 1 \quad \text{and} \quad \frac{dx_2}{dt} = 2t = 2x_1$$

We will be; our aim will be to solve the system of differential equations, so,  $x_1, x_2, \dots, x_n$  are unknown functions of the single variable  $t$ , systems of differential equations arise quite naturally in many scientific problems, a solution of system 1 is a set of  $n$  functions;  $x_1(t), x_2(t), \dots, x_n(t)$  such that  $\frac{dx_j}{dt} = f_j(t, x_1(t), x_2(t), \dots, x_n(t))$  that means the  $n$  functions  $x_1(t), x_2(t)$  and  $x_n(t)$  satisfy the system of differential equations given by 1.

Now, for example, let us consider  $x_1(t) = t$  and  $x_2(t) = t^2$  then these 2 functions provide us a solution of the simultaneous first order differential equations;  $\frac{dx_1}{dt} = 1$  and  $\frac{dx_2}{dt} = 2x_1$ , we can see, we have a system of 2 differential equations of first order, so here we can; if you take  $x_1(t) = t$  and  $x_2(t) = t^2$ , we can show that these 2 functions satisfying this system of differential equations. How it follows?

You can see  $\frac{dx_1}{dt} = 1$ ;  $x_1(t) = t$  implies  $\frac{dx_1}{dt} = 1$ , okay and  $x_2(t) = t^2$  gives you  $\frac{dx_2}{dt} = 2t$ , now  $t = x_1$ , so  $\frac{dx_2}{dt} = 2x_1$ . Therefore,  $x_1(t) = t$  and  $x_2(t) = t^2$  satisfy the system of differential equations of first order;  $\frac{dx_1}{dt} = 1$  and  $\frac{dx_2}{dt} = 2x_1$ , so they form a solution of this system of differential equations.

**(Refer Slide Time: 03:23)**

If we impose the initial condition on the functions  $x_1(t), x_2(t), \dots, x_n(t)$  as  $x_1(t_0) = x_1^0, x_2(t_0) = x_2^0, \dots, x_n(t_0) = x_n^0$  (1')

then the system (1) together with the initial conditions (1') is called as **initial-value problem**.

A solution of this initial value problem is 'n' functions  $x_1(t), x_2(t), \dots, x_n(t)$ , which satisfy (1) and the initial condition (1').

For example,  $x_1(t) = e^t$  and  $x_2(t) = 1 + \frac{e^{2t}}{2}$  is a solution of the IVP

$$\begin{aligned} \frac{dx_1}{dt} &= x_1, & x_1(0) &= 1 \\ \frac{dx_2}{dt} &= x_1^2, & x_2(0) &= \frac{3}{2} \end{aligned}$$

Now, if we impose the initial condition on the functions;  $x_1(t), x_2(t)$  and so on  $x_n(t)$  as  $x_1(t_0) = x_{10}, x_2(t_0) = x_{20}$  and so on  $x_n(t_0) = x_{n0}$ , then these system 1 together with the initial conditions 1 dash, okay is called an initial value problem. So, here we, you can see at  $t = t_0$ , the value of  $x_1$  is  $x_{10}$  at  $t = t_0$ , the value of  $x_2$  is  $x_{20}$  and so on, the value of  $x_n$  at  $t = t_0$  is  $x_{n0}$ , so if we are given these conditions together with the system 1, then the system 1 is called; is an initial value problem.

A solution of this initial value problem is n functions,  $x_1(t), x_2(t), x_n(t)$ , which satisfy the system 1 and the initial conditions given by 1 dash. For example, let us consider  $x_1(t) = e^t$  to the power t and  $x_2(t) = 1 + e^t$  to the power  $2t/2$ , then it is a solution of the IVP; IVP means initial value problem and the initial value problem here is  $dx_1/dt = x_1, dx_2/dt = x_1$  square, the initial conditions are  $x_1$  at  $t = 0$  is 1,  $x_2$  at  $t = 0$  is  $3/2$ .

Now, we have to show that  $x_1(t) = e^t$  to the power t and  $x_2(t) = 1 + e^t$  to the power  $2t/2$  is a solution of this initial value problem, so if you; first we have to show that  $x_1(t) = e^t$  to the power t and  $x_2(t) = 1 + e^t$  to the power  $2t/2$  satisfy the system of differential equations and then we have also to show that they satisfy the initial conditions,  $x_{10} = 1, x_{20} = 3/2$ . Now,  $x_1(t) = e^t$  to the power t implies  $dx_1/dt = e^t$  to the power t,  $e^t$  to the power t is  $x_1$ , so  $dx_1/dt = x_1$  is satisfy.

$x_2(t)$  is  $1 + e^t$  to the power  $2t/2$ , when you differentiate this with respect t, what you get is  $dx_2/dt = 2$  times  $e^t$  to the power  $2t/2$  that is  $e^t$  to the power  $2t$ , so  $dx_2/dt = e^t$  to the power  $2t$  which is  $= e^t$  to the power t whole square and so, we can write that as  $x_1$  square, so  $dx_2/dt =$

$x_1$  square, so  $x_1 t = e$  to the power  $t$  and  $x_2 t = 1 + e$  to the power  $2t/2$  satisfy the differential equations of the system and also you can see that  $x_1$  at  $t = 0 = e$  to the power  $0$ , which is  $= 1$ .

So,  $x_1 0 = 1$  is satisfied and  $x_2$  at  $t = 0$  is  $1 + e$  to the power  $0/2$ , which is  $= 1 + 1/2$  so, we have  $3/2$ , so  $x_2$  at  $t = 0$  is  $3/2$  and therefore,  $x_1 t = e$  to the power  $t$  and  $x_2 t = 1 + e$  to the power  $2t/2$  satisfies this system of differential equations together with the given initial conditions and therefore, they give us a solution of the initial value problem.

**(Refer Slide Time: 06:51)**

---

Since  $x_1(t) = e^t \Rightarrow \frac{dx_1}{dt} = e^t = x_1$

$\frac{dx_2}{dt} = e^{2t} = x_1^2(t), x_1(0) = 1, x_2(0) = \frac{3}{2}$

First order systems of differential equations also arise from higher order differential equations for a single variable  $y(t)$ . Every  $n^{\text{th}}$  order differential equation for the single variable  $y$ ,  $y^{(n)} = f(t, y, y', \dots, y^{(n-1)})$  can be converted into a system of  $n$  first-order differential equations for the variables

$$x_1(t) = y, x_2(t) = \frac{dy}{dt}, \dots, x_n(t) = \frac{d^{n-1}y}{dt^{n-1}}.$$

Then  $\frac{dx_1}{dt} = x_2, \frac{dx_2}{dt} = x_3, \dots, \frac{dx_{n-1}}{dt} = x_n$

and  $\frac{dx_n}{dt} = f(t, x_1, x_2, \dots, x_{n-1})$ , which is clearly a special case of (1).

---

Now, first order systems of differential equations also arise from higher order differential equations for a single variable  $y(t)$ , every  $n^{\text{th}}$  order differential equation for the single variable  $y$ , and this is  $n^{\text{th}}$  derivative of  $y$  with respect to  $t$ ,  $y^{(n)}$  we are representing;  $y^{(n)}$  represents  $\frac{d^n y}{dt^n} = f(t, y, y', y'' \dots, y^{(n-1)})$  that is  $n - 1$  of derivative of  $y$ , so it can be converted into a system of  $n$  first order differential equations for the variables.

Now, what we do is; we will convert this  $n^{\text{th}}$  order differential equation to a system of differential equations of first order, so let us write,  $x_1 t = y$ ,  $x_2 t = \frac{dy}{dt}$  and so on  $x_{n-1} t = \frac{d^{n-1}y}{dt^{n-1}}$  that is  $n - 1$ th derivative of  $y$  with respect to  $t$ , then from here, we can see that  $\frac{dx_1}{dt}$  will be  $= \frac{dy}{dt}$  and  $\frac{dy}{dt}$  is  $x_2$ , so  $\frac{dx_1}{dt} = x_2$ ,  $\frac{dx_2}{dt}$  will be  $\frac{d^2 y}{dt^2}$  so  $\frac{dx_2}{dt} = x_3$  and so on,  $\frac{dx_{n-1}}{dt} = x_n$ ;  $x_n - 1$  is the  $n - 2$ th derivative of  $y$  with respect to  $t$ .

So,  $\frac{dx_{n-1}}{dt}$  will be  $= n - 1$ th of the derivative of  $y$  and therefore it is  $= x_n$  and  $\frac{dx_n}{dt}$  is; if you differentiate this with respect to  $t$ , then  $\frac{dx_n}{dt}$  gives you  $n^{\text{th}}$  derivative of  $y$

with respect to  $t$ , so  $\frac{dx_n}{dt}$  can be written for this  $n$ th derivative of  $y$  with respect to  $t$  and we have  $f(t)$ ,  $y$  is  $x_1$ ,  $y'$  is  $x_2$  and so on,  $n - 1$ th derivative of  $y$  is  $x_n$ , so this is  $f(t)$ ,  $x_1$ ,  $x_2$  and so on  $x_n$ , which is clearly especially, so now, you can see there are  $n$  equations.

It is a system of  $n$  equations; first order  $n$  equations;  $\frac{dx_1}{dt} = x_2$ ,  $\frac{dx_2}{dt} = x_3$ ,  $\frac{dx_{n-1}}{dt} = x_n$  and that the  $n$ th equation is  $\frac{dx_n}{dt} = f(t)x_1 + x_2 + x_n$ , so this is a special case of the system given by equations 1.

**(Refer Slide Time: 09:38)**

**Example:** Convert the differential equation

$$a_n(t) \frac{d^n y}{dt^n} + a_{n-1}(t) \frac{d^{n-1} y}{dt^{n-1}} + \dots + a_0 y = 0$$

into a system of  $n$  first order equations.

**Solution:** let  $x_1(t) = y$ ,  $x_2(t) = \frac{dy}{dt}$ ,  $\dots$ ,  $x_n(t) = \frac{d^{n-1} y}{dt^{n-1}}$

Then  $\frac{dx_1}{dt} = x_2, \frac{dx_2}{dt} = x_3, \dots, \frac{dx_{n-1}}{dt} = x_n$

and

$$\frac{dx_n}{dt} = -\frac{1}{a_n(t)} [a_{n-1}(t)x_n + a_{n-2}(t)x_{n-1} + \dots + a_0 x_1]$$

Now, let us for example, convert the differential equation  $a_n(t) \frac{d^n y}{dt^n} + a_{n-1}(t) \frac{d^{n-1} y}{dt^{n-1}} + \dots + a_0 y = 0$  \* system of  $n$  first order differential equations. Now, as we have said, we will put  $x_1(t) = y$ ,  $x_2(t) = \frac{dy}{dt}$  and  $x_n(t) = n - 1$ th derivative of  $y$  with respect to  $t$ , then  $\frac{dx_1}{dt}$  is  $\frac{dy}{dt}$ , so  $\frac{dx_n}{dt}$  is  $x_2$ ,  $\frac{dx_2}{dt}$  is  $x_3$  and  $\frac{dx_{n-1}}{dt}$  is  $x_n$  because  $x_{n-1}$  is  $n - 2$ th derivative of  $y$  with respect to  $t$ , so when you differentiate  $x_{n-1}$  with respect to  $t$ , you get  $n - 1$  of the derivative of  $y$  with respect to  $t$ , which is assumed as  $x_n$ .

So,  $\frac{dx_{n-1}}{dt} = x_n$  and  $\frac{dx_n}{dt}$ , now you can see  $\frac{d^n y}{dt^n}$ ;  $\frac{d^n y}{dt^n}$  is  $\frac{dx_n}{dt}$  /  $dt$ , okay, so this is the  $\frac{dx_n}{dt}$ . What we do is; we transform all these terms to the other side and divide by  $a_n$ , assuming that  $a_n \neq 0$ , for  $n$ , so that  $\frac{dx_n}{dt}$  will be  $-1$  upon  $a_n$  and then  $a_{n-1}x_n$ , then  $a_{n-2}x_{n-1}$  and so on  $a_0$  and  $y$  is  $x_1$ , so we get  $n$  equations of first order, which are  $\frac{dx_1}{dt} = x_2$ ,  $\frac{dx_2}{dt} = x_3$  and so on  $\frac{dx_{n-1}}{dt} = x_n$ .

And the nth equation is  $dx_n/dt = -1$  upon ant, inside the bracket, we have an  $-1 t * x_n + n - 2t * x_{n-1}$  and so on  $a_0 x_1$ , so the bracketed expression or you can say the right hand side is a function of t and the n variables;  $x_1, x_2, x_n$ , so this system is of the form 1, so you can see that the nth order differential equation which is given to us has been converted into a system of n differential equations of first order.

**(Refer Slide Time: 12:15)**

**Example:** Convert the initial value problem

$$\frac{d^3 y}{dt^3} + \left(\frac{dy}{dt}\right)^2 + 3y = e^t; \quad y(0)=1, \quad y'(0)=0, \quad y''(0)=0$$

Into an initial value problem for the variables  $y$ ,  $\frac{dy}{dt}$ , and  $\frac{d^2 y}{dt^2}$ .

**Solution:** Let  $x_1(t) = y$ ,  $x_2(t) = \frac{dy}{dt}$ ,  $x_3(t) = \frac{d^2 y}{dt^2}$

Then

$$\frac{dx_1}{dt} = x_2, \quad \frac{dx_2}{dt} = x_3, \quad \frac{dx_3}{dt} = e^t - x_2^2 - 3x_1,$$

$$x_1(0) = 1, \quad x_2(0) = 0, \quad x_3(0) = 0.$$

Now, let us take an initial value problem, we can see this is the third order differential equation,  $d^3 y / dt^3 + dy/dt$  whole square  $+ 3y = e$  to the power t, the values of the dependent variable y at  $t = 0$  is given as 1, the derivative of y with respect to t;  $dy/dt$  at  $t = 0$  is 0 and  $d^2 y / dt^2$  at  $t = 0$  is = 0, so we have to convert this initial value problem into a system of differential equations.

Now, again, let us say  $x_1 t = y$ ,  $x_2 t = dy/dt$  and  $x_3 t = d^2 y / dt^2$  square, okay so then  $d^3 y / dt^3$  will be  $dx_3 / dt$ , so this is  $dx_3 / dt$ , okay and we can then, this is  $dx_3 / dt$  and these terms  $dy/dt$  whole square  $+ 3y$ , if you take to the other side, what you get?  $E$  to the power t  $- dy/dt$  is  $= x_2$ , okay, so  $x_2$  square, so  $e$  to the power t  $- x_2$  square  $- 3 * y$ ,  $y = x_1$ , so we get  $dx_3 / dt = e$  to the power t  $- x_2$  square  $- 3x_1$ .

Now, you can see, we have 3 equations; first equation is  $dx_1 / dt$ ;  $dx_1 / dt$  is  $= x_2$  because  $dx_1 / dt$  is  $dy/dt$  and  $dy/dt$  is  $x_2$ , so  $dx_1 / dt = x_2$  and  $dx_2 / dt$  is  $d^2 y / dt^2$  square, which is  $x_3$ , so  $dx_2 / dt$  is  $= x_3$  and  $dx_3 / dt$ , we have just now seen, it is  $e$  to the power t  $- x_2$  square  $- 3x_1$ . Now, y at 0 is given = 1, so you can see  $x_1 t = y$ , so at  $t = 0$ ,  $y = 1$ , therefore  $x_1 0 = 1$ , so  $x_1 0 = 1$  at  $t = 0$ ,  $dy/dt$  is = 0, so  $x_2 0 = 0$  and at  $t = 0$ ,  $d^2 y / dt^2$  square = 0, so  $x_3 0 = 0$ .

**(Refer Slide Time: 14:55)**

If each of the functions  $f_1, f_2, \dots, f_n$  in (1) is a linear function of the dependent variables  $x_1, x_2, \dots, x_n$ , then system of equations is called linear.

The most general system of  $n$  first-order linear equations is of the form

$$\begin{aligned} \frac{dx_1}{dt} &= a_{11}(t)x_1 + \dots + a_{1n}(t)x_n + g_1(t) \\ \frac{dx_2}{dt} &= a_{21}(t)x_1 + \dots + a_{2n}(t)x_n + g_2(t) \\ &\vdots \\ \frac{dx_n}{dt} &= a_{n1}(t)x_1 + \dots + a_{nn}(t)x_n + g_n(t) \end{aligned} \quad (2)$$

So, the initial value problem, okay, the given initial value problem is converted into a system of first order differential equations with the initial condition,  $x_1(0) = 1, x_2(0) = 0, x_3(0) = 0$ . Now, if each of the functions;  $f_1, f_2, f_n$  in the system 1, okay if each of the functions  $f_1, f_2, f_n$  in the system 1 is the linear function of the dependent variables  $x_1, x_2, x_n$ , then the system of equations is called linear.

Now, the most general linear system of  $n$  first order differential equations is of the form;  $dx_1/dt = a_{11}(t) * x_1$  and so on  $a_{1n}(t) * x_n + g_1(t)$ ,  $dx_2/dt = a_{21}(t) * x_1$  and so on  $a_{2n}(t) * x_n + g_2(t)$  and the  $n$ th equation is  $dx_n/dt = a_{n1}(t) * x_1$  and so on  $a_{nn}(t) * x_n + g_n(t)$ , so this is the most general system of  $n$  first order linear equations, a linear system it is, you can see the functions  $f_1, f_2, f_n$ , these are the functions of  $t, x_1, x_2, x_n$ , this  $f_1(t, x_1, x_2, x_n)$ , this  $f_2(t, x_1, x_2, x_n)$  and this  $f_n(t, x_1, x_2, x_n)$ .

**(Refer Slide Time: 16:25)**

If each of the  $n$  functions  $g_1, g_2, \dots, g_n$  is identically zero, then the system (2) is called homogeneous; otherwise it is non-homogeneous.

Let us consider the case where the coefficients  $a_{ij}$  do not depend on  $t$ .

A homogeneous linear system with constant coefficients

$$\begin{aligned} \frac{dx_1}{dt} &= a_{11}(t)x_1 + \dots + a_{1n}(t)x_n \\ \frac{dx_2}{dt} &= a_{21}(t)x_1 + \dots + a_{2n}(t)x_n \\ &\vdots \\ \frac{dx_n}{dt} &= a_{n1}(t)x_1 + \dots + a_{nn}(t)x_n \end{aligned} \quad (3)$$

In all these functions;  $f_1, f_2, f_n, x_1, x_2$  and so on  $x_n$ , they occur in the first degree and separately, okay, so it is a linear system. Now, if each of the  $n$  functions;  $g_1, g_2, g_n$  is identically 0, if it is so happens that  $g_1t, g_2t$  and so on  $g_nt$  are identically 0, then for every value of  $t$ ;  $g_1t, g_2t$  and so on  $g_nt = 0$  for every value of  $t$ , then we say that they are identically 0, then the system 2 is called homogeneous linear system otherwise, we call it a non-homogeneous linear system.

Now, let us consider the case, where the coefficients  $a_{ij}$  do not depend on  $t$ , so we are telling a particular case of the homogeneous system, where the coefficients of  $x_1, x_2, x_n$  that is  $a_{11}t$  and so on  $a_{1n}t, a_{21}t$  and so on  $a_{2n}t$  and so on  $a_{n1}t, a_{n2}t, a_{nn}t$ , they are just constants, they do not depend on  $t$ , so then such a system is called homogeneous linear system with constant coefficients.

**(Refer Slide Time: 17:53)**

(3) can be expressed in the concise form

$$\dot{x} = \frac{dx}{dt} = Ax \quad (4)$$

where

$$x(t) = \begin{bmatrix} x_1(t) \\ x_2(t) \\ \vdots \\ x_n(t) \end{bmatrix} \quad \text{and} \quad A = \begin{bmatrix} a_{11} & a_{12} & \dots & a_{1n} \\ a_{21} & a_{22} & \dots & a_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ a_{n1} & a_{n2} & \dots & a_{nn} \end{bmatrix}$$

Moreover if  $x_1(t), x_2(t), \dots, x_n(t)$  satisfy the initial conditions

$x_1(t_0) = x_1^0, x_2(t_0) = x_2^0, \dots, x_n(t_0) = x_n^0$ , then  $x(t)$  satisfies the initial value problem

So, this is of the form  $dx_1/dt = a_{11} * x_1$  and so on  $a_{1n} * x_n$ ,  $dx_2/dt = a_{21} * x_1$  and so on  $a_{2n} * x_n$  and  $dx_n / dt = a_{n1} * x_1$  and so on  $a_{nn} * x_n$ . Now, this system, we are writing it by equation 3, this system given by 3 can be expressed in the concise form. Now, you can see if the number of equations are very large, if the  $n$  is very large, then it will be very cumbersome to write these equations, so we can write them in a concise form using the vector notation.

What we do is; let if we denote  $x(t) = [x_1(t), x_2(t), \dots, x_n(t)]^T$ , this column vector, then this  $x(t)$  is called vector valued function and if you differentiate this  $x(t)$  with respect to  $t$ , then  $dx/dt$  is another vector valued function whose components are given by  $dx_1/dt, dx_2/dt$  and so on  $dx_n/dt$ , so therefore you can see the left hand side which is; in the first equation  $dx_1/dt$ , in the second equation  $dx_2/dt$ , in the last equation  $dx_n/dt$ , it can be put in the form of a vector notation which is  $\dot{x}$ .

$\dot{x}$  means  $dx/dt$ , so  $dx/dt$  will contain; is a column vector having  $n$  components  $dx_1/dt, dx_2/dt, dx_n/dt$ , the right hand side of these  $n$  equations is  $a_{11} x_1$  and so on  $a_{1n} x_n, a_{21} x_1 +$  and so on  $a_{2n} x_n, a_{n1} x_1$  and so on  $a_{nn} * x_n$ , it can be put in the form of a matrix  $A$  multiplied by the vector  $x$ , where the matrix  $A$  is  $a_{11}, a_{12}, a_{1n}, a_{21}, a_{22}, a_{2n}, a_{n1}, a_{n2}, a_{nn}$ , multiplied by; so the vector  $x$  that is  $x_1, x_2, x_n$ .

You can see if you multiply this matrix  $A$  by the vector  $x$ ;  $x_1, x_2, x_n$ , then the first row of  $Ax$  will be  $a_{11} x_1 + a_{12} x_2$  and so on  $a_{1n} x_n$  and then the second row of the matrix  $Ax$  will be  $a_{21} x_1, a_{22} x_2$  and so on  $a_{2n} x_n$ , the last row of matrix  $Ax$  will be  $a_{n1} x_1, a_{n2} x_2$  and so on

ann  $x_n$  and so, the  $n$  equations; the  $n$  equations are given by this 3 can be put in the form of a vector equation;  $\dot{x}/dt = Ax$ .

**(Refer Slide Time: 20:51)**

$$\dot{x} = Ax, \quad x(t_0) = x^0, \quad \text{where } x^0 = \begin{bmatrix} x_1^0 \\ x_2^0 \\ \cdot \\ \cdot \\ \cdot \\ x_n^0 \end{bmatrix}$$

Now, if  $x_1(t)$ ,  $x_2(t)$ ,  $x_n(t)$  satisfy the initial conditions that is at  $t = t_0$   $x_1$  is  $x_{10}$ ,  $x_2$  is  $x_{20}$  and  $x_n$  is  $x_{n0}$ , then  $x(t)$  satisfies the initial value problem, then we can write the system in the concise form  $\dot{x} = dx/dt = Ax$ ,  $x$  at  $t_0 = x_0$ , okay, because  $x(t)$  is  $= x_1(t)$ ,  $x_2(t)$ ,  $x_n(t)$ , so at  $t = t_0$ ,  $x(t_0)$  will be  $x_1(t_0)$ ,  $x_2(t_0)$ ,  $x_n(t_0)$  and we have assumed that  $x_1(t_0)$  is  $x_{10}$ ,  $x_2(t_0)$  is  $x_{20}$ ,  $x_n(t_0)$  is  $x_{n0}$ , so  $x(t_0) = x_1(t_0)$ ,  $x_2(t_0)$ ,  $x_n(t_0)$  that is  $x_{10}$ ,  $x_{20}$ ,  $x_{n0}$ .

And that we can write as  $x_0$ , so  $x(t_0) = x_0$ , where  $x_0 = x_{10}$ ,  $x_{20}$  and so on  $x_{n0}$ , so you can see that the initial value problem can be expressed in the concise form which is  $\dot{x} = Ax$ , where  $x(t_0) = x_0$  and  $x_0$  is this column vector.

**(Refer Slide Time: 21:44)**

**Example:** consider the system of equations

$$\frac{dx_1}{dt} = 3x_1 - 7x_2 + 9x_3$$

$$\frac{dx_2}{dt} = 15x_1 + x_2 - x_3$$

$$\frac{dx_3}{dt} = 7x_1 + 6x_3$$

then  $\dot{x} = \begin{bmatrix} 3 & -7 & 9 \\ 15 & 1 & -1 \\ 7 & 0 & 6 \end{bmatrix} x$  and  $x = \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix}$

Now, let us consider for example, the system of equations,  $dx_1/dt = 3x_1 - 7x_2 + 9x_3$ ,  $dx_2/dt = 15x_1 + x_2 - x_3$  and  $dx_3/dt = 7x_1 + 6x_3$ , then again if you take  $x_t$  to be the vector value function,  $x_1t, x_2t, x_3t$ , then  $\dot{x}$  will be  $dx_1/dt, dx_2/dt, dx_3/dt$ , so this left side can be represented by the vector valued function  $\dot{x}$  and the right hand side, we have; here the coefficient of  $x_1, x_2, x_3$  are  $3, -7, 9$ , here  $x_1, x_2, x_3$  have got coefficients,  $15, 1$  and  $-1$ .

Here,  $x_1$  has coefficient  $7$ ,  $x_2$  has coefficient  $0$ ,  $x_3$  has coefficient  $6$ , so the matrix  $a$ , okay will be say,  $3, -7, 9$ , first row of the matrix  $a$  will be  $3, -7, 9$ , second row will be  $15, 1, -1$  and the third row will be  $7$ , which is the coefficient of  $x_1$ , then coefficient of  $x_2$  is  $0$  and then coefficient of  $x_3$ , which is  $6$ , multiplied by the vector  $x$ ;  $x$  is the vector;  $x_1, x_2, x_3$ , so if you multiply this matrix  $a$  by the vector  $x_1, x_2, x_3$ , you get these right hand side.

And left hand side is this  $\dot{x}$ , which is  $dx_1/dt, dx_2/dt, dx_3/dt$ , so this system of 3 equations; this you can see, this is the homogenous system of linear differential equations of first order, this can be expressed in the concise form,  $\dot{x} = Ax$ , where  $A$  is this  $3$  by  $3$  matrix.

**(Refer Slide Time: 23:39)**

**Example:** The initial value problem

$$\frac{dx_1}{dt} = x_1 - x_2 + x_3, \quad x_1(0) = 1$$

$$\frac{dx_2}{dt} = 3x_2 - x_3, \quad x_2(0) = 0$$

$$\frac{dx_3}{dt} = x_1 + 7x_3, \quad x_3(0) = -1$$

can be written as

$$\dot{x} = \begin{bmatrix} 1 & -1 & 1 \\ 0 & 3 & -1 \\ 1 & 0 & 7 \end{bmatrix} x \quad \text{and} \quad x(0) = \begin{bmatrix} 1 \\ 0 \\ -1 \end{bmatrix}.$$

Let us now take up another problem, here we are taking initial value problem, so we have 3 equations;  $dx_1/dt = x_1 - x_2 + x_3$ ,  $dx_2/dt = 3x_2 - x_3$ ,  $dx_3/dt = x_1 + 7x_3$ , we are given that at  $t = 0$ ,  $x_1$  is 1, at  $t = 0$ ,  $x_2$  is 0, at  $t = 0$ ,  $x_3$  is -1. Now, as in the previous example, here also if you take  $x(t)$  to be the vector valued function having components  $x_1(t)$ ,  $x_2(t)$ ,  $x_3(t)$ , then the left hand side of this systems of equations is  $\dot{x}$  because  $\dot{x}$  is  $dx_1/dt$ ,  $dx_2/dt$ ,  $dx_3/dt$ , so  $\dot{x}$  and the coefficient matrix here.

The matrix of the unknown functions  $x_1$ ,  $x_2$ ,  $x_3$  is 1-1-1, okay, 1-1-1, then here, 0, 3, -1 because the coefficient of  $x_1$  is 0, so 0 \* 0 then 3, then -1 and here we get 1, then 0, then 7, the coefficient of  $x_2$  is 0 here, so 1, 0, 7 and then the vector  $x$  that is which has got components  $x_1$ ,  $x_2$ ,  $x_3$ . Now, let us count for these initial conditions, so  $x(t) = x_1, x_2, x_3$ , so  $x(0)$  is  $x_1(0)$  which is 1,  $x_2(0)$  which is 0, and then  $x_3(0)$  which is -1.

So, we have seen in this lecture how to write a linear system of first order differential equations, which is homogenous in the concise form also, we have seen how we can write initial value problem where we are given a system of first order differential equations homogeneous system with the initial conditions in the concise form, so by using the vector notation, we can write the equations in a concise form.

Now, in our next lectures, we shall see how we can solve system of homogeneous linear differential equations with constant coefficients. Thank you very much for your attention.
