Lecture - 09
Solution of Homogeneous Linear System with Constant Coefficients-I

Hello friends welcome to the lecture on solution of homogenous linear system with constant coefficients. Let us consider the vector differential equation $\dot{x} = Ax$ in what follows we will reduce the problem of finding all solutions of this vector differential equation to solving the system of equations $Ax = b$.

(Refer Slide Time: 00:39)

Let us consider $\dot{x} = Ax$ (1)

In what follows, we will reduce the problem of finding all solutions of (1) to solving $Ax=b$.

The eigen value-eigen vector method of finding solutions:

Consider the first-order linear homogeneous differential equation (1). Our aim is to determine n linearly independent solutions of (1).

Since first order and second order linear homogeneous scalar equations have exponential functions as solution, let $x(t) = e^{\lambda t} v$, where v is a constant vector, be a solution of (1). Then

$\frac{d}{dt} e^{\lambda t} v = \lambda e^{\lambda t} v$ and $A(e^{\lambda t} v) = e^{\lambda t} Av.$

Handwritten notes on the slide include:
 $\frac{dx}{dt} = a x$
 $\frac{dx}{dt} = a dt$
 $x = at + b$
 $x = c e^{at}$

At the bottom of the slide, there are logos for IIT Roorkee and NITEL Online Certification Course, and a page number '2'.

The eigen value-eigen vector method we are going to discuss to find all solutions of the vector differential equation $\dot{x} = Ax$. So let us consider the first-order linear homogeneous differential equation 1 which is $\dot{x} = x$. Our aim is to determine n linearly independent solutions of this vector differential equation. Now we know that first order and second order linear homogenous scalar equations have exponential functions as solution.

For example, you consider the first order liner homogenous scalar equation then it is $dx/dt =$ some constant times x , okay, which we can write as $dx/x = a dt$ and which gives us $\ln x = at +$ some constant which we can write as $\ln c$ so then $x = c$ times e to the power at . Same is the situation when you consider second order linear homogenous scalar equation, $d^2 x/dt^2 +$ some constant say α times $dx/dt + \beta$ times $x = 0$.

So we have exponential functions solutions of these first order and second order homogenous scalar equations therefore, what we do is we consider $x(t) = e^{\lambda t} v$ where v is the constant vector and take it to be a solution of equation 1. Now let us see that when you put $e^{\lambda t} v$ in the equation 1, we have on the left side dx/dt , so d/dt of $e^{\lambda t} v$ gives you λ times $e^{\lambda t} v$.

This is because $e^{\lambda t}$ we know $= 1 + \lambda t + \frac{\lambda^2 t^2}{2!} + \frac{\lambda^3 t^3}{3!} + \dots$. So when you differentiate this with respect to t , what you will get is d/dt of $e^{\lambda t}$ will give you $\lambda + \lambda^2 t + \frac{\lambda^3 t^2}{2!} + \dots$, okay, so we will get $\lambda e^{\lambda t}$ and then we will get $\lambda^2 t e^{\lambda t}$ and so on.

Which is $= \lambda e^{\lambda t} (1 + \lambda t + \frac{\lambda^2 t^2}{2!} + \dots)$ and so on and so it is $\lambda e^{\lambda t} v$. So when you differentiate $e^{\lambda t} v$ with respect to t where v is the constant vector what we get is $\lambda e^{\lambda t} v$ and by the matrix properties A is a matrix $\times e^{\lambda t} v$, $e^{\lambda t}$ is the scalar quantity $\times v$ will give you $e^{\lambda t} Av$.

So what we will get if you put it in this equation 1, $x(t) = e^{\lambda t} v$ what we get is? We get the following.

(Refer Slide Time: 04:40)

Hence, $x(t) = e^{\lambda t} v$ will be a solution of (1) if and only if $\lambda(e^{\lambda t} v) = e^{\lambda t} Av$, which gives $Av = \lambda v$. (2)

Thus, $x(t) = e^{\lambda t} v$ is a solution of (1) if, and only if, λ and v satisfy (2).

Definition: A non-zero vector v satisfying (2) is called an eigen vector of A with eigen value λ .

Remark: The vector $v=0$ is excluded because $A \cdot 0 = \lambda \cdot 0$ for any λ .

To find the eigen vectors of A , we rewrite (2) as $(A - \lambda I)v = 0$, which has a non-zero solution v only if $|A - \lambda I| = 0$. Hence the eigen values λ of A are the roots of the equation

$$Av = \lambda v$$

$$(A - \lambda I)v = 0$$

$$\Rightarrow |A - \lambda I| = 0$$

$$\lambda e^{\lambda t} v = e^{\lambda t} (Av)$$

$$\lambda v = Av$$

$$Av = \lambda v$$

$$A0 = \lambda v, \text{ for any scalar } v$$

So we get $\lambda e^{\lambda t} v = \lambda e^{\lambda t} v = \lambda e^{\lambda t} v = e^{\lambda t} \lambda v = e^{\lambda t} Av$, this is what we get. Now $e^{\lambda t}$ is never 0 for

any value of t , okay, so we can divide this equation by e to the power λt and we get $\lambda v = Av$. So $x(t) = e^{\lambda t} v$ will be a solution of equation 1 if and only if we have this equation $\lambda v = Av$ which gives us $Av = \lambda v$.

Thus $x(t) = e^{\lambda t} v$ is the solution of the equation 1 if and only if λ and v satisfy $Av = \lambda v$. Now a non-zero vector v satisfying this equation $Av = \lambda v$ is called an eigen vector of the matrix with eigen value λ . Now here the case $v = 0$ is excluded because it is an uninteresting case. You can see that we have $Av = \lambda v$, if you allow v to be 0 vector then $A * 0 \text{ vector} = \lambda * 0$ is true for any scalar λ .

So we discard this case and so the vector $v = 0$ is not allowed to be an eigen vector. So we will say that a nonzero vector v which satisfies $Av = \lambda v$ will be an eigen vector of A associated with the eigen value λ . To find the eigen vectors of A , we rewrite the equation $Av = \lambda v$ as now when you have $Av = \lambda v$ we have $(A - \lambda I)v = 0$. Now remember we always write $A - \lambda I$ because we cannot subtract a scalar λ from A .

So we multiply λ by identity matrix of the same order as A , okay. So $(A - \lambda I)v = 0$, this is what we get, now this equation has a nonzero solution only if determinant of $A - \lambda I = 0$, so determinant of $A - \lambda I$ must be 0. Because if determinant of $A - \lambda I$ is nonzero then $(A - \lambda I)^{-1}$ will exist and you can pre-multiply this equation $(A - \lambda I)v = 0$ by $(A - \lambda I)^{-1}$ and what you will get, $v = 0$, but $v \neq 0$.

So $(A - \lambda I)v = 0$ will give us a nonzero solution only when determinant of $A - \lambda I = 0$. Hence the eigen values λ of A are the roots of the characteristic equation $\det(A - \lambda I) = 0$.

(Refer Slide Time: 07:34)

$$0 = |A - \lambda I| = \begin{vmatrix} a_{11} - \lambda & a_{12} & \dots & a_{1n} \\ a_{21} & a_{22} - \lambda & \dots & a_{2n} \\ \dots & \dots & \dots & \dots \\ a_{n1} & a_{n2} & \dots & a_{nn} - \lambda \end{vmatrix}$$

and the eigen vectors of A are then the non-zero solutions of the equation $(A - \lambda I)v = 0$, for these values of λ .

The determinant of the matrix $(A - \lambda I)$ is clearly a polynomial in λ of degree n , with leading term $(-1)^n \lambda^n$.

If you expand this equation determinant $A - \lambda I = 0$ what you get is this determinant, $a_{11} - \lambda, a_{12}$ that is from the matrix A the diagonal elements of the matrix A are subtracted by λ . We are subtracting from A λ times identity matrix of order n . So this is what you get, so determinant of this $= 0$ gives us a polynomial equation in λ of degree n . The eigen vectors of A are then the nonzero solutions of.

So once you find the values of λ which satisfy this characteristic equation the corresponding eigen vectors are given by the nonzero solutions of the equation $(A - \lambda I)v = 0$, now the determinant of the matrix $A - \lambda I$ is clearly a polynomial in λ of degree n with the leading coefficient will be -1 to the power n λ to the power n .

(Refer Slide Time: 08:35)

This polynomial is called the characteristic polynomial of A and is denoted by $p(\lambda)$. For each root λ_j of $p(\lambda)$ there exists at least one non-zero vector v^j such that $Av^j = \lambda_j v^j$. Since $p(\lambda)$ has at most n distinct roots, every $n \times n$ matrix has at most n eigen values. Finally, since the space of all vectors $v = [v_1, v_2, \dots, v_n]^T$ has dimension n , every $n \times n$ matrix has at most n linearly independent eigen vectors.

Remark: Let v be an eigen vector of A with eigen value λ . Then $cv, c \neq 0$ is also an eigen vector of A, with the same eigen value. For each eigen vector v^j of A with eigen value λ_j , $x^j(t) = e^{\lambda_j t} v^j$ is a solution of (1). If A has n linearly independent eigen vectors v^1, v^2, \dots, v^n with eigen values $\lambda_1, \lambda_2, \dots, \lambda_n$ respectively ($\lambda_1, \lambda_2, \dots, \lambda_n$ need not be distinct), then $x^j(t) = e^{\lambda_j t} v^j, j = 1, 2, \dots, n$ are n linearly independent solutions of (1).

Handwritten notes on the slide:
 $Av = \lambda v$
 $A(cv) = c(Av) = c(\lambda v) = \lambda(cv)$
 $A(v^j) = \lambda_j v^j$
 $A(v^j) = \lambda_j v^j$
 $(A - \lambda_j I)v^j = 0$
 $p(\lambda) = |A - \lambda I|$
 $p(\lambda_j) = 0$

Now this polynomial is called the characteristic polynomial determinant of $A - \lambda I$ is called the characteristic polynomial of A and be denoted by $p(\lambda)$. So $p(\lambda) = \det(A - \lambda I)$. For each root λ_j of $p(\lambda)$ there are just at least one nonzero vector v_j such that $Av_j = \lambda_j v_j$. Suppose there is a value of λ say λ_j for which $p(\lambda)$ is 0 that is $p(\lambda_j) = 0$.

Then the corresponding nonzero eigen vector will be given by $Av_j = \lambda_j v_j$ or you can say $(A - \lambda_j I)v_j = 0$. So from here we will get at least one nonzero eigen vector corresponding to λ_j since $p(\lambda)$ is utmost n distinct roots, $p(\lambda)$ being a polynomial $p(\lambda)$ of degree n , so it has utmost and distinct roots, every $n \times n$ matrix has utmost n eigen values. Finally, since these space of eigen vectors $v = v_1, v_2, \dots, v_n$ it has got n components.

So the space of vectors has n dimension and dimension n and therefore every $n \times n$ matrix has n linearly independent eigen vectors at the most. Now if v is an eigen vector of A with eigen value λ then $c \cdot v$ where c is $\neq 0$ is also an eigen vector of A with the same eigen values. This is very simple to see. Suppose λ is an eigen value of A and v is the corresponding eigen vector.

Then we have $Av = \lambda v$. Now let us see $A(cv)$, c is a scalar which is nonzero we can write it as c times Av by the matrix properties so this is c times λv . So we have this is $= \lambda$ times cv . So we have $A(cv) = \lambda cv$. So if v is an eigen vector of A corresponding to the eigen value λ then cv where c is nonzero, c is taken to be nonzero because if you allow c to be 0, cv will be a zero vector.

So it cannot be an eigen vector so c is $\neq 0$ then if you take then cv is also an eigen vector of A with the same eigen value λ . Now for each eigen vector v_j of A with eigen value λ_j , $x(t) = e^{\lambda_j t} v_j$ is the solution of 1. We have seen that $x(t) = e^{\lambda t} v$ when we assume that as a solution of the equation $\dot{x} = Ax$ then we arrive at the equation where why we need to find the eigen vectors and eigen values of the matrix A .

So when you find corresponding to the eigen value λ_j , v_j as an eigen vector then corresponding to that $x(t)$ will be a solution of equation 1. If A has n linearly independently

eigen vectors v_1, v_2, \dots, v_n with eigen value $\lambda_1, \lambda_2, \dots, \lambda_n$ respectively. Note here that $\lambda_1, \lambda_2, \dots, \lambda_n$ need not be distinct, when $\lambda_1, \lambda_2, \dots, \lambda_n$ are all distinct eigen values we shall see that their corresponding eigen vectors are linearly independent.

But even in case where $\lambda_1, \lambda_2, \dots, \lambda_n$ are not all distinct we might have n linearly independent eigen vectors, so that is why suppose v_1, v_2, \dots, v_n are n linearly independent eigen vectors of the matrix A corresponding to the eigen value $\lambda_1, \lambda_2, \dots, \lambda_n$ respectively which need not be distinct then $\dot{x}_j = \lambda_j x_j, j = 1, 2$ and so on up to n are n linearly independent solutions of the vector differential equation 1 that is $\dot{x} = Ax$.

(Refer Slide Time: 12:53)

This follows from the theorem on test for linear independence and the fact that $x^j(0) = v^j$.

In this case, then, every solution of (1) is of the form

$$x(t) = c_1 e^{\lambda_1 t} v^1 + c_2 e^{\lambda_2 t} v^2 + \dots + c_n e^{\lambda_n t} v^n,$$

which is called the general solution of (1).

If A has n distinct real eigen values $\lambda_1, \lambda_2, \dots, \lambda_n$ with eigen vectors v^1, v^2, \dots, v^n , then the situation is the simplest because the vectors v^1, v^2, \dots, v^n are linearly independent as shown by the following theorem.

Solutions $x^1(t), x^2(t), \dots, x^k(t)$ of $\dot{x} = Ax$ are linearly independent if and only if $x^1(t_0), x^2(t_0), \dots, x^k(t_0)$

Now this follows from the theorem on test for linear independence, if you remember we did in the last lecture, we said that the solutions, $x_1(t), x_2(t), \dots, x_k(t)$, the k solutions of $\dot{x} = Ax$ are linearly independent if and only if $x_1(t_0), x_2(t_0), \dots, x_k(t_0)$ are linearly independent vectors so take value of $t = t_0$. So here if you choose $t = t_0$ to be 0 then we see that $x_j(t) = v_j$ and v_1, v_2, \dots, v_n are linearly independent. So $x_j(t)$ for $j = 1, 2, \dots, n$ are linearly independent.

And therefore the solutions $x_j(t)$ for $j = 1, 2$ and so on up to n are linearly independent and therefore general solution of the vector differential equation $\dot{x} = Ax$ can be written as $x(t) = c_1 e^{\lambda_1 t} v^1 + c_2 e^{\lambda_2 t} v^2 + \dots + c_n e^{\lambda_n t} v^n$ which is called the general solution. Now if A has n distinct real eigen values $\lambda_1, \lambda_2, \dots, \lambda_n$ will be the eigen vectors v_1, v_2, \dots, v_n .

Then the situation is the simplest because the eigen vectors v_1, v_2, \dots, v_n are linearly independent as shown by the following theorem.

(Refer Slide Time: 15:05)

Theorem: Any k eigen vectors v^1, v^2, \dots, v^k of A with distinct eigen values $\lambda_1, \lambda_2, \dots, \lambda_k$ respectively, are linearly independent.

Proof: For $k=1$ $c v^1 = 0 \Rightarrow c=0$ because $v^1 \neq 0$. The theorem is true for $k=1$.
 Assume that the result is true for $k=j$. Any set of j eigen vectors of A corresponding to j distinct eigen values is linearly independent. Let v^1, v^2, \dots, v^j be eigen vectors of A corresponding to j distinct eigen values $\lambda_1, \lambda_2, \dots, \lambda_j$ respectively.

$$c_1 v^1 + c_2 v^2 + \dots + c_{j+1} v^{j+1} = 0 \quad \text{--- (1)}$$

$$\Rightarrow A(c_1 v^1 + c_2 v^2 + \dots + c_{j+1} v^{j+1}) = A(0) = 0$$

$$c_1 (A v^1) + c_2 (A v^2) + \dots + c_{j+1} (A v^{j+1}) = 0$$

$$c_1 \lambda_1 v^1 + c_2 \lambda_2 v^2 + \dots + c_{j+1} \lambda_{j+1} v^{j+1} = 0 \quad \text{--- (2)}$$

Multiplying (1) by λ_1 and then subtracting from (2)

$$\begin{aligned} & c_2 (\lambda_2 - \lambda_1) v^2 \\ & + c_3 (\lambda_3 - \lambda_1) v^3 \\ & + \dots + c_{j+1} (\lambda_{j+1} - \lambda_1) v^{j+1} = 0 \end{aligned}$$

we get

$$\begin{aligned} & c_2 (\lambda_2 - \lambda_1) v^2 \\ & + \dots + c_{j+1} (\lambda_{j+1} - \lambda_1) v^{j+1} = 0 \end{aligned}$$

Any k eigen vectors v_1, v_2, \dots, v_k of A with distinct eigen values $\lambda_1, \lambda_2, \dots, \lambda_k$ respectively are linearly independent. Let us prove this theorem. We shall prove this theorem by induction on k . For $k=1$ the eigen vector v_1 is clearly linearly independent because if you take constant times $v_1 = 0$ then this implies $c = 0$ because v_1 is an eigen vector so $v_1 \neq 0$.

So for $k=1$ the theorem is true. The theorem is true for $k=1$. For $k=1$ we have seen whenever we consider $c v_1 = 0$ we get $c = 0$ and so v_1 is linearly independent. Now let us assume that the result is true for $k=j$ okay, so assume that which means that any set of j eigen vectors of A corresponding to distinct eigen values corresponding to j distinct eigen values is linearly independent.

So and then we shall show it for $j+1$, okay, we shall show that if you consider $j+1$ eigen vectors corresponding to $j+1$ distinct eigen values then they are linearly independent. So let us assume that let v_1, v_2, \dots, v_{j+1} be $j+1$ eigen vectors of A corresponding to $j+1$ distinct eigen values $\lambda_1, \lambda_2, \dots, \lambda_{j+1}$ respectively, okay.

Now in order to prove that v_1, v_2, \dots, v_{j+1} are linearly independent let us consider the equation $c_1 v_1 + c_2 v_2 + \dots + c_{j+1} v_{j+1} = 0$ vector, okay, where c_1, c_2, \dots, c_{j+1} are scalar. Now if we

want to show that v_1, v_2, v_{j+1} are linearly independent then we shall have to show that c_1, c_2, c_{j+1} are all 0s. Now what we do is let us operate on this equation by the matrix A , so when we operate by A we get this.

Now A matrix and this is 0 vector so we get 0 vector here okay, and lefthand side using the properties of matrixes we have c_1 times $Av_1 + c_2 Av_2$ and so on $c_{j+1} Av_{j+1} = 0$ and since v_1, v_2, v_{j+1} are eigen vectors of A corresponding to eigen values $\lambda_1, \lambda_2, \lambda_{j+1}$ Av_1 will be $\lambda_1 v_1$, this will be $\lambda_2 v_2$ and so on, this will be $\lambda_{j+1} v_{j+1} = 0$.

Now what we do is let us take it as equation 1, we multiply it by λ_1 , okay, we multiply equation 1 by λ_1 and then subtract from 2, so multiplying 1 by λ_1 and then subtracting from 2, what we notice is, let me write here, we will get, okay, so $c_1 \lambda_1 v_1$ will cancel with $c_1 \lambda_1 v_1$ and we will get $c_2 \lambda_2 - \lambda_1 * v_2 + c_3 \lambda_3 - \lambda_1 * v_3$ and so on.

$c_{j+1} \lambda_{j+1} - \lambda_1 * v_{j+1} = 0$ vector. Now v_2, v_3, v_{j+1} are j eigen vectors of A corresponding to the distinct eigen values $\lambda_2, \lambda_3, \lambda_{j+1}$ respectively, okay. So by our hypothesis since we have assumed that the result is true for $k = j$ okay, it follows that v_2, v_3, v_{j+1} are linearly independent so we have $c_2 \lambda_2 - \lambda_1 = 0, c_3 \lambda_3 - \lambda_1 = 0$ and so on $c_{j+1} \lambda_{j+1} - \lambda_1 = 0$.

Now we have assumed $\lambda_1, \lambda_2, \lambda_{j+1}$ to be distinct eigen values, so $\lambda_1 \neq \lambda_2, \lambda_1 \neq \lambda_3, \lambda_1 \neq \lambda_{j+1}$ so what we get here.

(Refer Slide Time: 22:29)

Since $\lambda_1, \lambda_2, \dots, \lambda_{j+1}$ are distinct, we get
 $c_2 = c_3 = \dots = c_{j+1} = 0$
 Then ① $\Rightarrow c_1 v^1 = 0$
 $\Rightarrow c_1 = 0$
 Thus, $c_1 = c_2 = \dots = c_{j+1} = 0$
 \Rightarrow the result is true for $k = j+1$
 By mathematical induction, the result holds for any k .

We get here c_2 since $\lambda_1, \lambda_2, \lambda_{j+1}$ are distinct we get c_2, c_3 , and so on, $c_{j+1} = 0$, now still we have to show that c_1 is 0, so what we do, we go back to the equation 1 okay, we go to the equation 1 put here $c_2 = 0, c_3 = 0, c_{j+1} = 0$. So then equation 1 gives us $c_1 v^1 = 0$ and we know that since v^1 is nonzero eigen vector $c_1 v^1 = 0$ implies $c_1 = 0$, so thus $c_1 = c_2$ and so on.

$c_{j+1} = 0$, which imply that that result is true for $k = j+1$, so by mathematical induction on k , the result holds for any k . So this is the proof of this result. Now let us take the example.

(Refer Slide Time: 24:12)

Example: Let $\dot{x} = \begin{bmatrix} 1 & -1 & 4 \\ 3 & 2 & -1 \\ 2 & 1 & -1 \end{bmatrix} x$
 The characteristic equation is $|A - \lambda I| = 0 \Rightarrow \begin{vmatrix} 1-\lambda & -1 & 4 \\ 3 & 2-\lambda & -1 \\ 2 & 1 & -1-\lambda \end{vmatrix} = 0$
 $\Rightarrow (1-\lambda) \{ (2-\lambda)(-1-\lambda) + 1 \} + 1 \{ 3(-1-\lambda) + 2 \} + 4 \{ 3 - (4-2\lambda) \} = 0$
 \Rightarrow Cubic equation in λ .
 The roots of this equation are $1, 3, -2$.

The eigen values of A are $\lambda_1 = 1, \lambda_2 = 3, \lambda_3 = -2$.

Suppose we have the vector differential equation $\dot{x} = Ax$ where A is the 3/3 matrix, $\begin{bmatrix} 1 & -1 & 4 \\ 3 & 2 & -1 \\ 2 & 1 & -1 \end{bmatrix}$ then we want to solve this vector differential equation using the method of eigen values eigen vector. So what we will do? We will find the characteristic equation, we write

the characteristic equation as determinant of $A - \lambda I = 0$, which gives us from the diagonal elements of A we subtract λ .

So $1 - \lambda$ -1 4 , 3 $2 - \lambda$, -1 , 2 1 $-1 - \lambda$ this determinant $= 0$, then we expand this determinant okay, what we will get, $1 - \lambda$ times $2 - \lambda$ * $-1 - \lambda$ and then we get $+ 1$, okay, then we get minus of this so $+ 1$ and then we have $3 * -1 - \lambda$ and then $+ 2$ and then we get 4 times $3 - 2 * 2 - \lambda$ that is $4 - 2 \lambda$, okay.

We can then simplify this equation. We will get a cubic equation in λ , so this will give us a cubic equation in λ . We can easily solve the cubic equation in λ , it will turn out that the roots are $1, 3, -2$, okay. So the eigen values of A are $\lambda_1 = 1$, $\lambda_2 = 3$ and $\lambda_3 = -2$.

(Refer Slide Time: 26:44)

Eigen vector for $\lambda_1 = 1$: $v^1 = \begin{bmatrix} -1 \\ 4 \\ 1 \end{bmatrix}$

then $x^1(t) = e^t \begin{bmatrix} -1 \\ 4 \\ 1 \end{bmatrix}$ ✓

$(A - \lambda I)v = 0$
 $(A - I)v = 0$

$$\begin{bmatrix} 0 & -1 & 4 \\ 3 & 1 & -1 \\ 2 & 1 & -2 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

$-v_2 + 4v_3 = 0 \Rightarrow v_2 = 4v_3$

$3v_1 + v_2 - v_3 = 0$
 $\Rightarrow 3v_1 + 3v_3 = 0 \Rightarrow v_1 = -v_3$

The vector $v = \begin{bmatrix} -v_3 \\ 4v_3 \\ v_3 \end{bmatrix}$
 $= v_3 \begin{bmatrix} -1 \\ 4 \\ 1 \end{bmatrix}$

taking $v_3 = 1$,
 $v^1 = \begin{bmatrix} -1 \\ 4 \\ 1 \end{bmatrix}$

10

Now what we will do corresponding to the eigen value $\lambda_1 = 1$ let us find the eigen vector for of the matrix A , okay. So we have to solve the equation $A - \lambda I v = 0$, okay, $\lambda I = 1$ here, so we get $A - I v = 0$, now $A - I$ means from the matrix A , we subtract the identity matrix so when you subtract the identity matrix from here the diagonal element will be subtracted by 1 each.

So we will get $0 -1 4$ that is the first row, then we get $3 1 -1$, and then we get $2 1 -2$. Let us say the vector v is $v_1 v_2 v_3$. Righthand side is 0 vector. So now we have to solve this equation, so the first we have a system of 3 equations here, homogenous system. So first

equation gives you $v_1 * 0 - v_2 + 4v_3 = 0$ that is to say $v_2 = 4v_3$. Second equation is $3v_1 + v_2 - v_3 = 0$.

And so we can put the value of v_2 here so this gives us $3v_1 + 4v_3 - v_3 = 0$ which gives us $v_1 = -v_3$. Okay, so now we need not solve the third equation $2v_1 + v_2 - 2v_3 = 0$ because the 3 equations are not linearly independent, one equation is always 0 equation, it is the linear combination of the other 2. This is because the determinant of $A - \lambda I = 0$. So what we do is, let us write the vector v then.

The vector v is $v_1 \ v_2 \ v_3$, v_1 is $-v_3$, v_2 is $4v_3$ and v_3 is arbitrary. So I can write it as v_3 times $-1 \ 4 \ 1$ okay. Now choosing $v_3 =$ any nonzero scalar value we can choose for v_3 . So let us choose the convenient value $v_3 = 1$ taking $v_3 = 1$ we get v_1 . We get the vector v , $v = -1 \ 4 \ 1$, okay, so this is vector v_1 corresponding to eigen value $\lambda = 1$ and therefore one solution of the vector differential equation we can find for the eigen value $\lambda = 1$ and eigen vector v_1 .

It is $e^{\lambda t}$ to the power λt , $\lambda = 1$ means e^t and then $v_1 = -1 \ 4 \ 1$, so this is one solution of the given differential equation.

(Refer Slide Time: 30:17)

Eigen vector for $\lambda_2 = 3$: $v^2 = \begin{bmatrix} 1 \\ 2 \\ 1 \end{bmatrix}$ then $x^2(t) = e^{3t} \begin{bmatrix} 1 \\ 2 \\ 1 \end{bmatrix}$

Eigen vector for $\lambda_3 = -2$: $v^3 = \begin{bmatrix} -1 \\ 1 \\ 1 \end{bmatrix}$ then $x^3(t) = e^{-2t} \begin{bmatrix} -1 \\ 1 \\ 1 \end{bmatrix}$

$(A+2I)v=0$ $(A-3I)v=0$

$$\begin{bmatrix} -2 & -1 & 4 \\ 3 & -1 & -1 \\ 2 & 1 & -4 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 11

Now similarly we can find for the eigen value $\lambda = 2 = 3$ let us find the eigen vector. So for $\lambda = 3$ we have to solve $(A - 3I)v = 0$, $A - 3I$ if you find, $A - 3I$ will be you subtract 3 from the diagonal elements of the matrix A so when you subtract 3 from here you get $-2 \ -1 \ 4$, so you get $-2 \ -1 \ 4$ and then you have here $3 \ -1 \ -1$ and then here you have $2 \ 1 \ -4$. Now we can

see here first equation is $-2v_1 - v_2 + 4v_3 = 0$ and third equation is just minus times the first equation.

Because it is $2v_1 + v_2 - 4v_3 = 0$ so we can consider only first 2 equations that is first 2 rows $-2 -1 4, 3 -1 -1$ and the 2 equations in 3 unknowns v_1, v_2, v_3 can be solved okay, and we will get the eigen vector for $\lambda = 3$ is v_2 that is $1 2 1$ and the corresponding solution will then be $x_2(t) = e^{3t}$ to the power λt that is $e^{3t} * 1 2 1$ and for $\lambda = -2$ similarly we can find for $\lambda = -2$ we need to solve the equation $A - \lambda I$.

That is $A + 2I v = 0$, so to the matrix A , we add 2 times the identity matrix that means we add in the diagonal elements of A and then the matrix that we get that will be $A+2I$, so $A+2I v = 0$ can be solved and we get $v_3 = -1 1 1$. So the third solution is then given by $x_3(t) = e^{-2t}$ and then $-1 1 1$, okay.

(Refer Slide Time: 32:47)

Then solution of the given system is of the form

$$x(t) = c_1 e^t \begin{bmatrix} -1 \\ 4 \\ 1 \end{bmatrix} + c_2 e^{3t} \begin{bmatrix} 1 \\ 2 \\ 1 \end{bmatrix} + c_3 e^{-2t} \begin{bmatrix} -1 \\ 1 \\ 1 \end{bmatrix}$$

$$= \begin{bmatrix} -c_1 e^t + c_2 e^{3t} - c_3 e^{-2t} \\ 4c_1 e^t + 2c_2 e^{3t} + c_3 e^{-2t} \\ c_1 e^t + c_2 e^{3t} + c_3 e^{-2t} \end{bmatrix}$$

The solutions of the given system is then of the form $x(t) = c_1 e^t$ okay, so c_1 times $x_1(t)$, c_2 times $x_2(t)$, c_3 times $x_3(t)$, so we get, if you multiply these $c_1 e^t$ to the power t , $c_2 e^{3t}$ to the power $3t$, $c_3 e^{-2t}$ to these 3 column vectors and then add what you get is this $-c_1 e^t + c_2 e^{3t} - c_3 e^{-2t}$ and then $4c_1 e^t + 2c_2 e^{3t} + c_3 e^{-2t}$ and then $c_1 e^t + c_2 e^{3t} + c_3 e^{-2t}$.

And then you get here the third component is $c_1 e^t + c_2 e^{3t} + c_3 e^{-2t}$ so this is the general solution of the given vector differential equation. Now

let us take another problem this is the initial value problem, here we are given the vector differential equation $\dot{x} = Ax$.

(Refer Slide Time: 33:45)

Example: Let $\dot{x} = \begin{bmatrix} 1 & 12 \\ 3 & 1 \end{bmatrix} x, x(0) = \begin{bmatrix} 0 \\ 1 \end{bmatrix}$.

$$\begin{vmatrix} 1-\lambda & 12 \\ 3 & 1-\lambda \end{vmatrix} = 0$$

$$\Rightarrow (1-\lambda)^2 - 36 = 0$$

$$\Rightarrow (1-\lambda) = \pm 6$$

The eigen value of A are $\lambda_1 = 7, \lambda_2 = -5$.

And we are also given an initial condition that is at $x, t = 0, x = 01$ okay. So again we shall write the characteristic equation here $1 - \lambda, 12, 3, 1 - \lambda = 0$ and this will give you quadratic equation in $\lambda, 1 - \lambda$ whole square $-36 = 0$. So you can say that $1 - \lambda = \pm 6$ okay, so taking 6, when you take 6 here then we get $\lambda = 1 - 6$, so -5 okay.

And when you take -6 here then $1 - \lambda = -6$ gives you $\lambda = 7$, so we get 2 eigen values of $\lambda, 7$ and -5 and they are both real and distinct so corresponding eigen vectors will be linearly independent.

(Refer Slide Time: 34:49)

Eigen vector for $\lambda_1 = 7$: $v^1 = \begin{bmatrix} 2 \\ 1 \end{bmatrix}$ then $x^1 = e^{7t} \begin{bmatrix} 2 \\ 1 \end{bmatrix}$ ✓

Eigen vector for $\lambda_2 = -5$: $v^2 = \begin{bmatrix} -2 \\ 1 \end{bmatrix}$ then $x^2 = e^{-5t} \begin{bmatrix} -2 \\ 1 \end{bmatrix}$ ✓

$x(t) = c_1 x^1(t) + c_2 x^2(t)$
 $x(0) = c_1 x^1(0) + c_2 x^2(0)$
 $\begin{bmatrix} 0 \\ 1 \end{bmatrix} = c_1 \begin{bmatrix} 2 \\ 1 \end{bmatrix} + c_2 \begin{bmatrix} -2 \\ 1 \end{bmatrix} \Rightarrow$
 $2c_1 - 2c_2 = 0$
 $c_1 + c_2 = 1$
 $\Rightarrow c_1 = c_2 = \frac{1}{2}$

So for $\lambda_1 = 7$ it turns out that v_1 is $\begin{bmatrix} 2 \\ 1 \end{bmatrix}$ so $x_1(t)$ is $e^{7t} \begin{bmatrix} 2 \\ 1 \end{bmatrix}$ and $\lambda_2 = -5$ gives you $v_2 = \begin{bmatrix} -2 \\ 1 \end{bmatrix}$, so $x_2(t) = e^{-5t} \begin{bmatrix} -2 \\ 1 \end{bmatrix}$ okay. So the general solution is what, $x(t) = c_1 x_1(t) + c_2 x_2(t)$ and we then use the initial condition that is the value of x at $t = 0$ which is given as $\begin{bmatrix} 0 \\ 1 \end{bmatrix}$. So if you do that okay, what you get is this.

This will be $x(0)$ put $t = 0$ here so $x(0) = c_1 x_1(0) + c_2 x_2(0)$, okay, $x(0)$ is given to be $\begin{bmatrix} 0 \\ 1 \end{bmatrix}$, so $\begin{bmatrix} 0 \\ 1 \end{bmatrix} = c_1 \begin{bmatrix} 2 \\ 1 \end{bmatrix} + c_2 \begin{bmatrix} -2 \\ 1 \end{bmatrix}$ we can find from here when you put $t = 0$ you get $\begin{bmatrix} 2 \\ 1 \end{bmatrix}$ here and then you get $c_2 \begin{bmatrix} -2 \\ 1 \end{bmatrix}$ when you put $t = 0$ you get $\begin{bmatrix} -2 \\ 1 \end{bmatrix}$ okay, so this gives you $2c_1 - 2c_2 = 0$ and then $c_1 + c_2 = 1$. So it is clear, $c_1 = c_2$ and so $c_1 + c_2 = 1$, so this gives you $c_1 = c_2 = 1/2$ each, okay. So put the value $1/2$ here so then $x(t) = 1/2 x_1(t) + x_2(t)$, so this is the particular solution in given initial value problem.

(Refer Slide Time: 36:50)

Then solution is

$$x(t) = \begin{bmatrix} e^{7t} - e^{-5t} \\ \frac{1}{2}e^{7t} + \frac{1}{2}e^{-5t} \end{bmatrix}$$

o

So $x(t)$ turns out to be $e^{7t} \begin{bmatrix} 2 \\ 1 \end{bmatrix} - e^{-5t} \begin{bmatrix} 2 \\ 1 \end{bmatrix} / 2 + e^{-5t} \begin{bmatrix} -2 \\ 1 \end{bmatrix}$. That is all for this lecture. Thank you very much for your attention.
