Lecture – 14
Cayley-Hamilton Theorem and Minimal Polynomials

Hello friends so, welcome to lecture series on Matrix Analysis with Applications. So, in today's lecture we will focus on Cayley-Hamilton theorem and minimal polynomial that, what Cayley-Hamilton theorem is and how can you find the minimal polynomial using characteristic polynomial. So, what Cayley-Hamilton theorem state let us see.

(Refer Slide Time: 00:45)

The slide content is as follows:

Cayley-Hamilton theorem

Every square matrix A is a root of its characteristic polynomial.

or

Let T be a linear operator on a finite dimensional vector space V . If f is the characteristic polynomial for T , then $f(T) = \mathbf{0}$, where $\mathbf{0}$ is the zero transformation.

IT Roorkee | NPTEL ONLINE CERTIFICATION COURSE | 2

Cayley-Hamilton theorem states that every matrix A , every square matrix A is a root of its characteristic polynomial ok. So, what does it mean let us see.

minus 1 plus C 2 lambda raised to power minus 2 and so, on plus minus 1 raised to power n C n is equal to 0 ok. So, this polynomial lambda this polynomial is called characteristic polynomial ok.

So, how many how many roots this equation is having, this equation is having n number of roots. Suppose a roots are lambda 1, lambda 2 up to lambda n, roots maybe distinct roots maybe real roots maybe complex ok. Some roots are equal some are distinct anything.

Now, we have already discussed at some of the eigenvalues is equal to trace of the matrix, trace means sum of the diagonal elements, that is sum of over i sum of a i i, a 11 plus a 22 plus a 33 upto a nn and i is varying from 1 to n. And this also we have discussed at product of eigenvalues is nothing, but determinant of A ok.

Now, Cayley-Hamilton theorem is states that for if this is characteristic polynomial of matrix A ok, then matrix always satisfies characteristic polynomial.

(Refer Slide Time: 04:39)

$$\begin{aligned}
 A_{n \times n} &\rightarrow |A - \lambda I| = 0 \\
 &\Rightarrow \lambda^n - C_1 \lambda^{n-1} + C_2 \lambda^{n-2} + \dots + (-1)^n C_n = 0
 \end{aligned}$$

Then,

$$A^n - C_1 A^{n-1} + C_2 A^{n-2} + \dots + (-1)^n C_n I = O.$$

$$\begin{aligned}
 \text{adj}(A - \lambda I) &= B_1 \lambda^{n-1} + B_2 \lambda^{n-2} + \dots + B_n \\
 \text{Here } B_1, B_2, \dots, B_n &\text{ are the matrices of order } n \times n.
 \end{aligned}$$

$$(A - \lambda I) \text{adj}(A - \lambda I) = |A - \lambda I| I$$

$$A = \begin{pmatrix} a_{11} & a_{12} & \dots & a_{1n} \\ a_{21} & a_{22} & \dots & a_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ a_{n1} & \dots & \dots & a_{nn} \end{pmatrix}_{n \times n}$$

$$(A - \lambda I) = \begin{pmatrix} a_{11} - \lambda & a_{12} & \dots & a_{1n} \\ a_{21} & a_{22} - \lambda & \dots & a_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ a_{n1} & \dots & \dots & a_{nn} - \lambda \end{pmatrix}$$

$$C_{ij} = (-1)^{i+j} M_{ij}$$

$$A \text{adj} A = |A| I$$

That means, that means if for a matrix a of order n cross n, the characteristic polynomial is determinant A minus lambda I is equal to 0, which is equal to suppose lambda raised to power n minus C 1 lambda raised to power n minus 1, C 2 lambda raised to power n minus 2 and so, on plus minus 1 raised to power n C n is equal to 0.

Then by Cayley-Hamilton theorem $A^n - C_1 A^{n-1} + C_2 A^{n-2} - \dots + (-1)^{n-1} C_{n-1} A + (-1)^n C_n I = 0$ should be a 0 matrix, or a null matrix; that means, if you have a characteristic polynomial corresponding to matrix A. It always be satisfied by the matrix itself, that is a main statement of Cayley Hamilton theorem.

Now, how can we prove it, how can we prove that a matrix whose characteristic polynomial is given by suppose this expression, it will be satisfied by the matrix also. So, let us try to prove this result the proof of the Cayley-Hamilton theorem you see, for in order to prove let us find adjoint of $A - \lambda I$. Let us find adjoint of $A - \lambda I$. You see what is what is a matrix suppose a matrix is a_{11}, a_{12} and so, on up to a_{1n} , a_{21}, a_{22} and so on up to a_{2n} and so on up to a_{nn} .

This is $n \times n$ matrix A and, what is $A - \lambda I$, $A - \lambda I$ will be $a_{11} - \lambda, a_{12}$ and so on a_{1n} , $a_{21}, a_{22} - \lambda$ and so on a_{2n} and here a_{n1}, a_{n2} and so on up to $a_{nn} - \lambda$, this is $A - \lambda I$.

Now, if you want to find out adjoint of this matrix $A - \lambda I$. So, how you will procedure you first find cofactors of each element, take the transpose of the matrix found by the cofactors, that will be the adjoint of that matrix. If suppose you want to find out the cofactor of this matrix this element, the first element you want to find out cofactor of this element will leave, this column will leave this row and the determinant of $(n-1) \times (n-1)$ matrix will be the cofactor corresponding to first element.

Similarly, if you want to find out cofactor of a_{ij} elements say for example, then you leave this column and you leave this row and, you find out the cofactor of determinant of the remaining matrix will be the cofactor of that particular element with of course, cofactor of C_{ij} is $(-1)^{i+j}$ minor of i, j that we already know.

So, so what is it mean it mean that we if you want to find out the cofactor of any element of this matrix say first element. So, it will be the highest power of λ will be λ^{n-1} raised to power $n-1$, you see you want if you see cofactor of this element. Then the determinant of this will contain λ^{n-1} . Now, λ^n raised to power n , if you want to find cofactor of this element, then the highest power of λ will be λ^{n-2} ok.

So, if you find cofactors of each and every element of this matrix. So, this will be something like, you can say that it is $B_1 \lambda^{n-1} + B_2 \lambda^{n-2} + \dots + B_n$. This B_1, B_2 up to B_n they are the matrices itself ok, where itself the matrices there here B_1, B_2 and so, on up to B_n are the matrices ok. Because, because when you write the determinant of this matrix you open it will contain λ^{n-1} and the other terms.

Similarly, when you take the cofactors of other element and so on so, you will get $\lambda^{n-1} A + B_1$. Similarity $\lambda^{n-2} A + B_2$ and so on up to B_n . You can easily verify this result by taking a 3 cross 3 matrix so, you will find that B_1, B_2 up to B_n in that case is are the matrixes of order $n \times n$ of order $n \times n$.

Now, we know that we also know that $A - \lambda I$ into adjoint of $A - \lambda I$ that means, A into adjoint of A we already know it is equal to determinant of A times identity ok. So, this is a matrix into adjoint of the matrix is equal to determinant of $A - \lambda I$ into I , this we already know. So, so you substitute this expression who are here. So, what you will get what you will get you see.

(Refer Slide Time: 10:06)

$$\begin{aligned}
 (A - \lambda I) \text{adj}(A - \lambda I) &= |A - \lambda I| I \\
 \Rightarrow (A - \lambda I) (B_1 \lambda^{n-1} + B_2 \lambda^{n-2} + \dots + B_n) &= (A^n - C_1 A^{n-1} + \dots + (-1)^n C_n) I \\
 -B_1 &= I \quad \xrightarrow{A^n} \\
 A B_1 - B_2 &= -C_1 I \quad \xrightarrow{A^{n-1}} \\
 B_n A &= (-1)^n C_n I \quad \xrightarrow{I} \\
 A^n - C_1 A^{n-1} + C_2 A^{n-2} + \dots + (-1)^n C_n I &= 0.
 \end{aligned}$$

We are having $A - \lambda I$ into adjoint of $A - \lambda I$, we are taking is equal to determinant of $A - \lambda I$ times identity.

This implies a minus lambda I, this is we are resuming it is equals to B_1 lambda raised to power $n-1$, B_2 raised to power $n-2$ and so, on up to B_n is equal to determinant of. Now, determinant of $A - \lambda I$ is we already know that it is lambda raised to power $n - C_1$ raised to power $n-1$ and so, on up to minus 1 raised to power n into C_n times identity.

This we have already assumed at the determinant of this matrixes lambda raised to the power $n - C_1$ lambda raised to power minus 1 and so, on minus 1 raised to power and C_n times identity.

Now, let us compare the coefficient from both the sides, you see what is the coefficient of lambda raised to the power n , from here and here when you multiply these two brackets, then lambda raised to power n will be minus B_1 , from this into this itself ok. And that must be equal to I from here.

Now, lambda raised to power $n-1$ lambda raised to the power $n-1$, when you multiply this with this element. So, it is $A B_1$ and this with this I mean this element the second element of this bracket, that is minus of B_2 that will be equal to lambda raised to power $n-2$ from here C_1 times identity.

Similarly, if you similarly if you take the lambda raised to the power 0 from here. So, lambda raised to power 0 will be this into this that is B_n into A from here and no other term and, that will be equal to minus 1 raised to the power $n - C_n$ times identity. Now, now you multiply the first equation by A raised to power n , the second equation by A raised to power $n-1$. The last equation with the identity and you add them, when you multiply this by A raised to power n multiply this by a raised to power $n-1$. Then it become A into A raised to the power $n-1$ will become A raised to power n into B_1 .

So, these two will cancel out. Now, similarly when you multiply B_2 with this element this will be minus A raised to power $n-1$ into B_2 which will be cancel from the next expression, term in the next expression. And similarly last expression will be cancels from the second last one ok. So, when you add them when you add them it we obtain A raised to the power $n - C_1$, A raised to power $n-1$ plus C_2 , A raised to power $n-2$ and so on plus minus 1 raised to power $n - C_n$ times identity will be equal to 0.

So, hence we have obtained hence we obtained this result, which states that I mean which tells us that characteristic polynomial will be satisfied by the matrix itself. So, hence we got the proof of the Cayley-Hamilton theorem.

(Refer Slide Time: 13:31)

Problem

- Let $A = \begin{bmatrix} 2 & -2 \\ -2 & 5 \end{bmatrix}$, verify Cayley-Hamilton theorem and hence find A^{-1} , $adj(A)$ and A^6 .

3

So, suppose we are having this problem now, matrix A for simplicity we have taken example of 2 cross 2. Similarly we can go for 3 cross 3, or higher orders. Now, let us suppose a is this matrix ok, we have to verify Cayley-Hamilton theorem and hence find A inverse adjoint of A and A raise to power 6.

(Refer Slide Time: 13:47)

$$A = \begin{pmatrix} 2 & -2 \\ -2 & 5 \end{pmatrix}$$

$$|A - \lambda I| = 0$$

$$\Rightarrow \begin{vmatrix} 2-\lambda & -2 \\ -2 & 5-\lambda \end{vmatrix} = 0$$

$$\Rightarrow (2-\lambda)(5-\lambda) - 4 = 0$$

$$\Rightarrow \lambda^2 - 7\lambda + 6 = 0$$

$$A^2 - 7A + 6I = 0$$

$$\underline{\text{LHS}} \quad A^2 - 7A + 6I$$

$$A^2 = \begin{pmatrix} 2 & -2 \\ -2 & 5 \end{pmatrix} \begin{pmatrix} 2 & -2 \\ -2 & 5 \end{pmatrix}$$

$$= \begin{pmatrix} 8 & -14 \\ -14 & 29 \end{pmatrix}$$

$$A^2 - 7A + 6I = \begin{pmatrix} 8 & -14 \\ -14 & 29 \end{pmatrix} - \begin{pmatrix} 14 & -14 \\ -14 & 35 \end{pmatrix} + \begin{pmatrix} 6 & 0 \\ 0 & 6 \end{pmatrix}$$

$$= \begin{pmatrix} 0 & 0 \\ 0 & 0 \end{pmatrix} = 0$$

Now, what is A here? A is you see A is 2 minus 2 minus 2 and 5. First we will find out the characteristic polynomial of this matrix A and, from there we will try to verify Cayley-Hamilton theorem. So, what is the characteristic polynomial determinant of A minus lambda I is equal to 0 is a characteristic polynomial. So, this implies determinant of 2 minus lambda minus 2 minus 2 5 minus lambda determinant should be 0.

So, this implies 2 minus lambda into 5 minus lambda minus 4 should be 0. This implies lambda square, this is minus 7 lambda plus 10 minus 4 is plus and minus 4 is plus 6 equal to 0. So, this is a characteristic polynomial of this matrix A. Now, what from Cayley-Hamilton theorem, from Cayley-Hamilton theorem we must have A square minus 7 A plus 6 I should be 0, this we have to verify in order to verify you simply take left hand side, left hand side is a square minus 7 A plus 6 I.

And we have to show that it is equal to null matrix. So, first find A square, what is a square A square is 2 minus 2 minus 2 5 into A itself 2 minus 2 minus 2 5, when you multiply these two this row this column, it is 4 plus 4 is 8. This row this column minus 4 minus 10 minus 14. This row this column minus 4 minus 10 minus 14, this row this column is 4 plus 10 is 14.

Now, you now let us try to find this expression A square minus 7 A plus 6 I, which is 8 minus 14 minus 14 14 minus 7 times A you multiply this with 7. So, it is it will be 14 minus 14 minus 14 7 5's at it is 35 7 into 5 is 35 plus 6 I 3 6 0 0 6.

Now, 8 plus 6 is 14 and 14 minus 14 is 0 similarly, minus 14 and plus 14 is 0 minus 14 plus 14 is 0 and, it is 14 14 plus 6, 14 plus 6 is 20. So, let us let us again verify this thing, it is this row this column that is 4 plus 25 ok.

So, here we have a doubt here is a correction, you see this element. It is 4 this row this column that is 4 plus 25 is 29 ok. So, this element is 29 now 29 plus 6 is 35 and 35 minus 35 is 0. So, it is 0 0 0 0 so, it A an unmatrix 0 ok. So, hence we have hence this Caylen Hamilton theorem is verified. Now, we have to find out inverse of a using Cayley-Hamilton theorem so, how we will find that.

(Refer Slide Time: 17:11)

$$\begin{aligned}
 A^2 - 7A + 6I &= 0 & \lambda_1 \lambda_2 &= 6 = |A| \neq 0 \\
 A^{-1}(A^2 - 7A + 6I) &= 0 & A &= \begin{pmatrix} 2 & -2 \\ -2 & 5 \end{pmatrix} \\
 A - 7I + 6A^{-1} &= 0 & & \\
 \Rightarrow A^{-1} &= \frac{1}{6}(7I - A) & 7I - A &= \begin{pmatrix} 7 & 0 \\ 0 & 7 \end{pmatrix} - \begin{pmatrix} 2 & -2 \\ -2 & 5 \end{pmatrix} \\
 &= \frac{1}{6} \begin{pmatrix} 5 & 2 \\ 2 & 2 \end{pmatrix} & &= \begin{pmatrix} 5 & 2 \\ 2 & 2 \end{pmatrix} \\
 A^{-1} &= \frac{\text{adj } A}{|A|} \Rightarrow \text{adj } A = A^{-1} \cdot |A| & & \\
 &= 6A^{-1} = \begin{pmatrix} 5 & 2 \\ 2 & 2 \end{pmatrix} & &
 \end{aligned}$$

So, for this matrix we have seen that $A^2 - 7A + 6I$ is equal to 0, this we have obtained by Cayley-Hamilton theorem. Now, what is the determinant of the matrix, determinant of the matrix is simply product of eigenvalues and, product of eigenvalues is simply given by the last term upon first term that is 6 that is the determinant.

So, determinant is not equal to 0 this means inverse exist. Now, first we have to get the ensure that inverse exist and, for inverse to exist matrix must be invertible, I mean non singular for that determinant must be non 0 and, from here the product of eigenvalue is 6. So, we can say that determinant is not equal to 0 so, A inverse exist.

Now, how to find A inverse. Now, since A inverse exist and A satisfied this equation by Cayley-Hamilton theorem. So, we can multiply both the sides, or we can operate both the sides by A inverse. So, let us operate both the sides by A inverse, it is 0 A inverse into A square is A minus 7 times identity plus 6 times A inverse should be 0.

Now, this implies A inverse will be you can put all the other terms on left hand side, it is $7I$ minus A ok. Now, what is A ? A is given to us as it is $\begin{pmatrix} 2 & -2 \\ -2 & 5 \end{pmatrix}$, so what is $7I$ minus A $7I$ minus A will be $\begin{pmatrix} 7 & 0 \\ 0 & 7 \end{pmatrix}$ minus A A is $\begin{pmatrix} 2 & -2 \\ -2 & 5 \end{pmatrix}$ and, this will be $\begin{pmatrix} 5 & 2 \\ 2 & 2 \end{pmatrix}$ plus 2 is 2, it is again 2 a 7 minus 2 is 2.

So, this A inverse will be 1/6th of this method, it is 5 2 2 2. So, this should be the inverse of this matrix. Now, next is we have to find out adjoint of A. Now, we know that A inverse is adjoint of A upon determinant of A. So, this implies adjoint of A will be A inverse times determinant of A. Now, determinant of A is 6 that we already shown. So, it is 6 into A inverse and A inverse is this expression so, 6 is cancel out. So, adjoint of this matrix recently this matrix now, next we have to find out A raised to power 6 for the same problem ok.

(Refer Slide Time: 19:52)

$$\begin{aligned}
 A^2 - 7A + 6I &= 0 \\
 A^2 &= 7A - 6I \quad \checkmark \\
 A^3 &= 7A^2 - 6A = 7(7A - 6I) - 6A \\
 &= 49A - 42I \\
 A^4 &= 49A^2 - 42A = 49(7A - 6I) - 42A \\
 &= \underline{\hspace{2cm}} \\
 A^5 &= \underline{\hspace{2cm}} \\
 A^6 &= \underline{\hspace{2cm}}
 \end{aligned}$$

$A^6 = \alpha A + \beta I$

Now, by Cayley-Hamilton theorem the characteristic polynomial is this ok, A square minus 7 I plus 6 I equal to 0 and, we have to find A raised to the power 6.

So, it is very easy to find out using this expression you see, A square is 7 A minus 6 I, you can find a cube by multiplying both sides by A, it is 7 A square minus 6 A 7 times. Now, A square again you substitute this value it is 7 A minus 6 I minus 6 A, it is equal to now 42 minus 6, 42 minus 6 is a 36 A minus 42 I ok, it is 49, it is 49 minus 6 so, it is 49 minus 6 is 43 it is 43 A minus 42 I.

Similarly, you can now multiply again you can multiply by A both the sides. So, it is a raised to power 4 43 A square minus 42 A. So, 43 A square A square is again 7 A minus 6 I from this expression, minus 42 A you can simplify this. And again you can multiply by a raised to the power 5, I mean a both the sides and substitute A square from this expression and finally, A raised to the power 6 ok.

So, finally, you will get an expression of A raised to the power 6 of this form $\alpha A^6 + \beta A^5 + \dots + \gamma A + \delta I$, where α and β can be computed by successive computation, then you can substitute A^6 because you know the matrix A and identity you already know you can easily find out A^6 ok.

Another way out is using Cayley-Hamilton theorem, it is like you are you might be seeing that for 2 cross 2 matrix, either you can multiply A by 6 times A square, then A cube then A raised to the power 4 A raised to the power 5 and, then A raised to power 6, but if it is a larger matrix of order say 10 cross 10, then finding A raised to the power 6 is the difficult task.

So, but by the Cayley-Hamilton theorem using Cayley-Hamilton theorem, it is easy to find out. So, this is the main importance of Cayley-Hamilton theorem to find out the higher powers of A to find out A inverse adjoint of A and other things about the matrix A .

(Refer Slide Time: 22:41)

Monic Polynomial

A polynomial $f(x) \in F[x]$, given by $f(x) = a_n x^n + a_{n-1} x^{n-1} + \dots + a_1 x + a_0$, is monic if $a_n = 1$.

Minimal Polynomial

Let T be a linear operator on a finite dimensional vector space V . Then there exists a unique monic polynomial of minimum degree, $m_T(x)$, such that

$$m_T(T)(v) = 0 \quad \forall v \in V$$

then $m_T(T)$ is said to be the minimal polynomial of T .

4

Now, what is monic polynomial a polynomial $f(x)$ given by $f(x) = a_n x^n + a_{n-1} x^{n-1} + \dots + a_1 x + a_0$ is said to be monic. If the leading coefficient is 1, if this leading coefficient which is a coefficient of highest power of this polynomial is 1, then this polynomial is called monic polynomial ok.

Now, what do you mean by minimal polynomial. Let T be a linear operator on a finite dimensional vector space V , then there exist a unique monic polynomial of minimum degree $m(T, x)$ such that $m(T, T)v = 0$ for all v in V , then this $m(T, x)$ is called minimal polynomial of T .

(Refer Slide Time: 23:32)

$$A_{4 \times 4} \rightarrow (\lambda - 1)^2 (\lambda - 2) (\lambda - 3) = 0$$

$$(A - I)^2 (A - 2I) (A - 3I) = 0.$$

$$(\lambda - 1) (\lambda - 2) (\lambda - 3) \rightarrow (A - I)(A - 2I)(A - 3I) = 0$$

or

$$(\lambda - 1)^2 (\lambda - 2) (\lambda - 3) \rightarrow (A - I)^2 (A - 2I)(A - 3I) = 0.$$

So, what does it mean basically suppose, suppose A is a matrix of order say 4 cross 4 ok. And its characteristic polynomial is suppose $\lambda - 1$ whole $\lambda - 2$ whole $\lambda - 3$ of course, if it is a order 4 cross 4.

So, the degree of the characteristic polynomial will be 4. So, it will be having 4 roots, suppose all the 4 roots are real. So, roots are roots of I mean characteristic roots are or the eigenvalues of this matrix are suppose 1 1 2 3. So, what is the characteristic polynomial these are characteristic polynomial of A , this matrix A and by the Cayley-Hamilton theorem we can easily say that $A - I$ whole square into $A - 2I$ into $A - 3I$ this should be 0, because by the Cayley-Hamilton theorem matrix satisfies characteristic polynomial.

So, hence this will be also this will be also be equal to 0. Now, minimal polynomial is the lowest degree polynomial, for which is to be satisfied by the matrix itself, you see what is the degree of this polynomial degree of polynomial is 4 ok. The important property of minimal polynomial is it contains all the different roots ok, it contains all the different

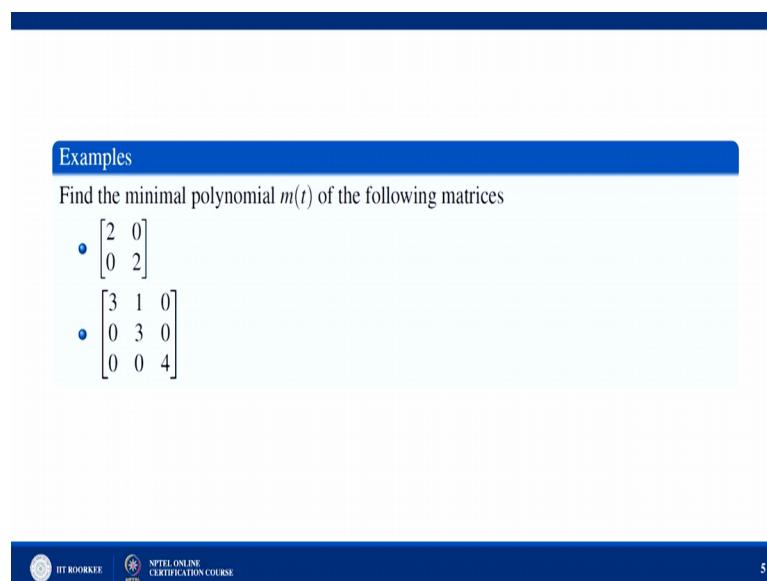

roots that different roots are 1 2 and 3. So, minimal polynomial will always contain lambda minus 1, lambda minus 3 at least ok.

All the irreducible roots it will be having the minimal polynomial. So, so either it is either it is this polynomial, which is the lowest degree polynomial, which maybe the lowest degree polynomial. And A is be satisfied in this expression or it will be characteristic polynomial itself, I mean I want to say that matrix A will be satisfied by either this, or this for this it is a for this it is a obviously, true because by the Cayley-Hamilton theorem.

But we need a polynomial which is lowest degree. So, it may be this polynomial also. So, for this polynomial we have to check whether A is as is satisfying this expression or not. If A satisfying this expression so, this will be the minimal polynomial. Otherwise this is the minimum polynomial which is of course, be satisfied by A by the Cayley-Hamilton theorem ok.

So, minimal polynomial has important property number 1 it is a of lowest degree polynomial, which is satisfied by the matrix itself, it contains all the irreducible factors, all the linear factors which is the characteristic polynomial is having ok. Now, suppose you want to find out minimum polynomial correspond to a matrix A how you will proceed.

(Refer Slide Time: 00:27)

Examples

Find the minimal polynomial $m(t)$ of the following matrices

- $\begin{bmatrix} 2 & 0 \\ 0 & 2 \end{bmatrix}$
- $\begin{bmatrix} 3 & 1 & 0 \\ 0 & 3 & 0 \\ 0 & 0 & 4 \end{bmatrix}$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 5

So, let us discuss it by an example, suppose you are having the first problem 2 0 0 2 2 0 0 2.

(Refer Slide Time: 27:04)

$$A = \begin{pmatrix} 2 & 0 \\ 0 & 2 \end{pmatrix}$$

$$|A - \lambda I| = 0$$

$$\Rightarrow \begin{vmatrix} 2-\lambda & 0 \\ 0 & 2-\lambda \end{vmatrix} = 0 \Rightarrow (2-\lambda)^2 = 0.$$

$$\begin{aligned} (2-\lambda) \checkmark & \rightarrow \underline{2I - A} = \begin{pmatrix} 2 & 0 \\ 0 & 2 \end{pmatrix} - \begin{pmatrix} 2 & 0 \\ 0 & 2 \end{pmatrix} \\ (2-\lambda)^2 \checkmark & = \begin{pmatrix} 0 & 0 \\ 0 & 0 \end{pmatrix} \end{aligned}$$

So, what is the characteristic polynomial of this matrix this, which means determinant 2 minus lambda 0 0 2 minus lambda should be 0, or it implies 2 minus lambda whole square is equal to 0. So, this is a characteristic polynomial of this matrix A, how many roots it is having only 2 roots both are equal lambda equal to 2 2 ok.

Now, the minimal polynomial is the lowest degree polynomial contains all the irreducible roots, all the linear roots all the different roots distinct roots ok. So, that means, the minimal polynomial will be either 2 minus lambda, or 2 minus lambda square ok. It is either having 2 minus lambda, or itself. This is will be always satisfied by matrix itself by the Cayley-Hamilton theorem.

So, we have to check whether this is the satisfied by the matrix, or not if it is satisfied by the matrix; that means it is a minimal polynomial. So, this means we have to check that 2 I minus A should be 0, or it is not 0 let us see 2. So, 2 I is 2 0 0 2 and A is simply of course, the same thing.

So, it is comes out to be a null matrix; that means, that means this expression, this expression satisfying by matrix A; that means a minimal polynomial of correspond to

this matrix is $2 - \lambda$ ok. It is of degree 1 not 2. So, the minimal polynomial of this matrix is $2 - \lambda$.

(Refer Slide Time: 29:02)

$$A = \begin{pmatrix} 3 & 1 & 0 \\ 0 & 3 & 0 \\ 0 & 0 & 4 \end{pmatrix}$$

ch polynomial
 $(\lambda - 3)^2 (\lambda - 4)$

minimal poly.
 $(\lambda - 3)(\lambda - 4)$

or
 $(\lambda - 3)^2 (\lambda - 4)$
 ↓
 minimal polynomial

$$= (A - 3I)(A - 4I)$$

$$= \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} -1 & 1 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & 0 \end{pmatrix}$$

$$= \begin{pmatrix} 0 & -1 \\ & & -1 \end{pmatrix}$$

≠ 0

Now, let us take the second example to see whether it is what is the meaning of polynomial of this. The second example is if you see A is A here is $3 \ 1 \ 0 \ 0 \ 3 \ 0 \ 0 \ 0 \ 4$. It is the upper triangular matrix you can easily see upper triangular matrix and, the in case of upper triangular matrix eigenvalues are simply the diagonal elements.

So, what are eigenvalues of this matrix these are 3 3 and 4. And if you know the eigenvalues you can simply find out characteristic polynomial, which is $\lambda - 3$ whole square into $\lambda - 4$ that is that we can easily see. So, characteristic polynomial of this matrix A will be nothing, but $\lambda - 3$ whole square into $\lambda - 4$. Now, you have to see what is the minimal polynomial of this matrix A. So, to see the minimal polynomial of this matrix A minimal polynomial is lowest degree polynomial which is satisfied by the matrix itself.

So, either it is so, minimal polynomial of this matrix, is either $\lambda - 3$ into $\lambda - 4$, or $\lambda - 3$ whole square into $\lambda - 4$, because it contain all the different roots, or the distinct roots all the factors having distinct roots.

So, this is obviously, satisfied because by the Cayley-Hamilton theorem. Let us see whether it is satisfied or not if it is satisfied, then this will be the minimal polynomial of

this matrix A. So, we have to see basically that A minus 3 I into A minus 4 I, what is expression this let us see what is A minus 3 I, it is 0 1 0 it is 0 0 0 0 4 and, what is a minus 4 I, it is A minus 3 I is 0 1 0 0 0 1 0 0 0 and 0 0 0 1 ok.

Because you are multiplying this we are subtracting 3 with each diagonal elements. Now, A minus 4 I will be minus 1 minus 1 1 0 0 minus 1 0 0 0 0. Now, what is the port of these two you multiplied this with this 0, you multiplied this with this is minus. If one element is non-zero, if one element comes out to be non 0, this means it is not equal to a null matrix. And if it is not equal to null matrix; that means, this cannot be the minimal polynomial

So, what is the minimal polynomial then the minimum polynomial will be the this expression this will be the minimal polynomial this. So, in this way we can find out the minimal polynomial of a matrix A ok.

(Refer Slide Time: 31:52)

$$A_{5 \times 5} \rightarrow (\lambda - 1)^3 (\lambda - 2) (\lambda + 3) = 0$$

Minimal poly

$$(\lambda - 1) (\lambda - 2) (\lambda + 3)$$

$$(\lambda - 1)^2 (\lambda - 2) (\lambda + 3)$$

$$(\lambda - 1)^3 (\lambda - 2) (\lambda + 3) \checkmark$$

So, basically if I have I am having a matrix A of order say 5 cross 5 and the characteristic polynomial is suppose lambda minus 1, whole raised to power 3 into lambda minus 2 into lambda plus 3. Suppose is equal to 0, then the minimal polynomial of this I mean for this matrix A corresponding characteristic polynomial may be so, what about cases we have to check.

For minimal polynomial we have to check this product, whether it is 0 or not this product, whether it is 0 or not and this product this is of course, 0 by the Cayley-Hamilton theorem. So, if these two are not equal to 0. So, the matrix characteristic polynomial itself is a minimal polynomial ok, but we have to check for these two also whether these are 0 or not ok.

So, first you will check for this if it is equal to 0. So, this the least lowest degree polynomial, which is satisfied by the matrix. Otherwise we check for this, if these two are not equal to 0, then the characteristic polynomial itself will be the minimal polynomial ok.

The slide contains a blue header bar at the top. Below it is a white box with a blue border containing the text 'Properties'. Underneath this box is a list of three numbered items. At the bottom of the slide is a dark blue footer bar with logos and text.

Properties

- 1 The minimal polynomial $m(t)$ of a matrix (linear operator) A divides every polynomial that has A as a zero, i.e. $m(t)$ divides the characteristic polynomial of A .
- 2 The characteristic polynomial and minimal polynomial of the matrix A have the same irreducible factors.
- 3 A scalar λ is an eigen value of the matrix A iff λ is a root of the minimal polynomial of A .

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 6

So, what are property minimal polynomial, the minimal polynomial $m(t)$ of matrix A divides every polynomial that has A as a zero, that is $m(t)$ divide the characteristic polynomial of A .

So, always minimal polynomial divides it is characteristic polynomial ok. Number 2 it has the characteristic polynomial and minimal polynomial of matrix A has the same irreducible factors, which we have discussed. And number 3, A scalar λ is eigenvalue of matrix A if and only if λ is a root of a minimal polynomial of A also. So, if λ is eigenvalue it is also it is always a root of minimal polynomial also.

So, these are some of the important properties of minimal polynomial. So, in this lecture we have seen that that, how we can find out characteristic polynomial, I mean how we can see and see the advantage, or the applications of Cayley-Hamilton theorem, how can you find out minimal polynomial corresponding to a matrix A ok. In the next few lectures, we will see some of the important properties of important advantage of minimal polynomial so.

Thank you.
