Lecture – 15
Diagonalization

Hello friends, so welcome to lecture series on Matrix Analysis with Applications. So, today we will discuss about Diagonalization, what do you mean by diagonalization of the matrices?

(Refer Slide Time: 00:44)

Similar matrices

Let A and B be two square matrices of order n , over the field F . Then, A is said to be similar to B if there exists an invertible matrix P such that

$$B = P^{-1}AP$$

We write symbolically $A \sim B$ (A is similar to B)

IIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 2

So, let us discuss now first of all before starting diagonalization let us discuss similar matrices. So, let A and B be two square matrix of order n over the field F , then A is said to be similar to B if there exists an invertible matrix P such that B equal P inverse AP and we symbolically write A is A similar to B like this ok. So, what do you mean by basically two similar matrices?

(Refer Slide Time: 01:18)

$$\begin{aligned} A \sim B \quad \text{if } \exists \text{ an invertible matrix } P \\ \text{st} \quad AP = PB \quad \text{or} \quad \boxed{B = P^{-1}AP} \\ \\ |B| = |P^{-1}AP| = |P^{-1}| |A| |P| \\ = \frac{1}{|P|} |A| |P| \\ = |A| \end{aligned}$$

So, we say that a matrix A is similar to a matrix B if there exists an invertible matrix, invertible matrix P such that AP is equal to PB or B is equal to $P^{-1}AP$. So, one thing is very like obvious from this fact. So, what is that that determinant of B and determinant of A are equal. This is very clear from here you can see, the determinant of B will be determinant of $P^{-1}AP$, and that will be equal to determinant of P^{-1} determinant of A determinant of P . Since, determinant of A into B is equal to determinant of A into determinant of B .

Now, determinant of P^{-1} is 1 upon determinant of P into determinant of A into determinant of P . So, these two cancels out, so it is equal to determinant of A . So, what we obtain the first property of similar matrices is that if 2 matrices A and B are similar then their determinant are always equal, this is a first property of similar matrices. The second property is that if 2 matrices are similar then they have same eigenvalues ok.

(Refer Slide Time: 02:57)

$$\begin{aligned}
 A \sim B &\Rightarrow \exists P \text{ st } AP = PB. \\
 &\text{or} \\
 A &= PBP^{-1} \\
 AX &= \lambda X, \quad X \neq 0 \\
 (PBP^{-1})X &= \lambda X \\
 \Rightarrow B(P^{-1}X) &= P^{-1}\lambda X \\
 \Rightarrow B(P^{-1}X) &= \lambda(P^{-1}X) \\
 \text{let } P^{-1}X &= Y \\
 BY &= \lambda Y
 \end{aligned}$$

suppose $Y = 0$
 $P^{-1}X = 0$
 $\Rightarrow X = 0$ which contradicts that $X \neq 0$
 Hence $Y \neq 0$.

So, how can you prove this? So, if A is similar to B this means this means implies there exist P such that AP is equal to PB or A is equals to P B P inverse ok. If A is similar to B, now we have the second property we have to show that if 2 matrices similar then they have same eigenvalues.

So, how we can proceed for this supposes A x equal to lambda x where x is not equal to 0. So, what does it mean this means that A has an eigenvalue lambda and the corresponding eigenvector is x ok. Now since, A similar to B that means, A is equal to P B P inverse, so you can replace A by P B P inverse ok. Now this implies B into P inverse x this we can easily write you pre multiplied both the size by P inverse because P is invertible. So, it is P inverse of lambda x and this implies B into P inverse x is equal to lambda times P inverse x ok, because lambda is a scalar can be taken out. Now, this P inverse x you can suppose let this P inverse x is y suppose, then this is B y equal to lambda y.

So, what we have concluded we have concluded that B matrix as an eigenvalue lambda and the corresponding eigenvector is y. In order to proved at y is an eigenvector you have to showed at y is not equal to 0 of course. So, that is that is very easy to show suppose y is equal to 0, we can prove this by contradiction if y is equal to 0; that means, P inverse x equal to 0. Now x is not equal to 0 x is not equal to 0 from here because it's an eigenvector and this matrices invertible this is a system of linear equations ok.

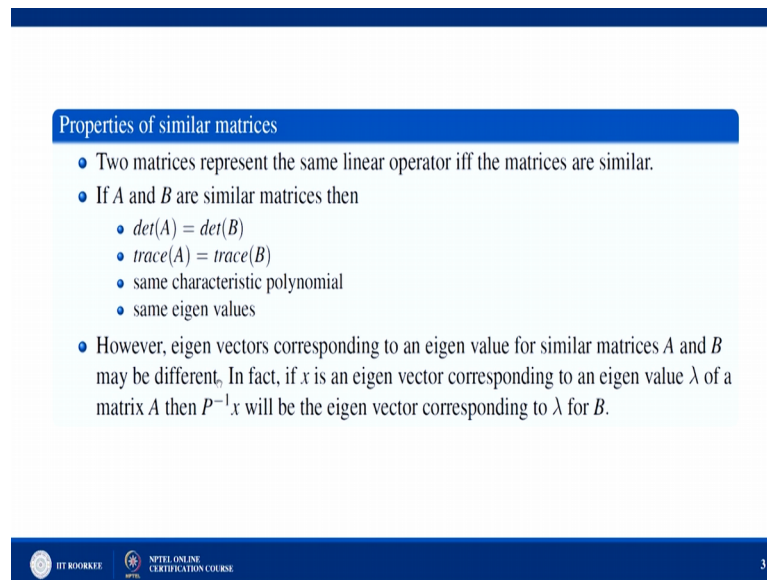

As system of linear equation with this matrices invertible; that means, only unique solution which is the x equal to 0, but x is not equal to 0. So, it is a contradiction because, from here it implies that x equal to 0 which contradicts that x is not equal to 0.

Hence, y is not equal to 0 because, because whenever we write such express that $B y$ equal to λy , if y is not equal to 0 then only we can say that the eigenvalues λ and the corresponding eigenvector is y ok. So, what we have concluded basically we have taken a matrix A with eigenvalue λ and the corresponding eigenvector x , and using the property of similar matrices we have shown that a matrix B as a same eigenvalue λ and the corresponding eigenvector is y ok. So, we can say that similar matrices have same eigenvalues of course, their eigenvector may not be same if x is an eigenvector corresponding to λ here for A , then a corresponding to λ for B the eigenvector is y which is $P^{-1}x$.

Now, if they have same eigenvalues this clearly shows that the characteristic polynomials of similar matrices are same, since roots are same. If roots are same eigenvalues are same; that means, characteristic polynomial of matrix A and B which are similar to each other are also same ok. Now since they have same eigenvalues; that means, that trace of the 2 matrices are also same trace is nothing, but sum of eigenvalues. Now if the similar matrix are same eigenvalues; that means, sum of eigenvalues are also same and this implies that trace of 2 matrix are also equal ok.

So, what we have concluded, we have concluded that if 2 matrices A and B are similar then their determinant are also are equal. Then the tracers trace of the 2 matrices are equal trace of A is equal to trace of B , where A and B are similar matrices they have the same characteristic polynomial. And hence they have the same characters same characteristic roots or eigenvalues ok, eigenvectors may not be same ok.

(Refer Slide Time: 07:40)

The slide is titled "Properties of similar matrices" and contains the following text:

- Two matrices represent the same linear operator iff the matrices are similar.
- If A and B are similar matrices then
 - $\det(A) = \det(B)$
 - $\text{trace}(A) = \text{trace}(B)$
 - same characteristic polynomial
 - same eigen values
- However, eigen vectors corresponding to an eigen value for similar matrices A and B may be different. In fact, if x is an eigen vector corresponding to an eigen value λ of a matrix A then $P^{-1}x$ will be the eigen vector corresponding to λ for B .

At the bottom of the slide, there are logos for IIT ROORKEE and NPTEL ONLINE CERTIFICATION COURSE, and the number 3 in the bottom right corner.

So, these are what they are in these properties you can easily see, if 2 matrices represent the same linear operator if and only if the matrices are similar number 1. If matrices are similar then the linear operators are also same or they have if they have the linear operator then the matrices are similar. If A and B are similar matrices then determinant are equal, trace are equal same characteristic polynomial and same eigenvalues this way we have already discussed

However eigenvector corresponding to an eigenvalue for similar matrix A and B may be different. In fact, if x is an eigenvector corresponding to an eigenvalue λ of matrix A , then $P^{-1}x$ will be the eigenvector corresponding to λ for the matrix B this we have already discussed.

(Refer Slide Time: 08:29)

Example

- If $A = \begin{bmatrix} 4 & -2 \\ 3 & 6 \end{bmatrix}$ and $B = \begin{bmatrix} 25 & 30 \\ -\frac{27}{2} & -15 \end{bmatrix}$ then A and B are similar, because there exists a matrix $P = \begin{bmatrix} 1 & 2 \\ 3 & 4 \end{bmatrix}$ such that

$$B = P^{-1}AP.$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 4

Now, let us discuss one example suppose A is this matrix and B is this matrix then A and B are similar, how we have concluded this is very easy to conclude basically if you have 2 matrices A and B any 2 matrices A and B ok.

(Refer Slide Time: 08:51)

A B P

$$AP = PB$$
$$P = \begin{pmatrix} a & b \\ c & d \end{pmatrix}$$
$$ad - bc \neq 0$$

You have to check whether these 2 matrices are similar or not. So, you basically take arbitrary matrix P such that A P is equals to P B it here A and B are 2 cross 2 matrices. So, you can take P as a b c d, then you can solve the left hand side you can solve the right hand side ok. And you will get 4 equations in 4 unknowns, you can find a b c d, and if

you find $abcd$ such that this matrix P is invertible that is $a d - b c$ is not equal to 0 that clearly means matrix A and B are similar.

Because we have shown the existence of such P such that such invertible P , such that $A P$ equal to $P B$; So, here also here also you can find such P which we are getting as this you can easily verify here that B equal to $P^{-1} A P$. So, we can say that these 2 matrices are similar, you can also verify here you can see that trace is 10 here the trace is also 10, here the determinant is 24 minus 6, 24 plus 6 30. And here also if you simplify you will get 30 the determinant of P because they are similar. Now, in terms of linear operator what do you mean by diagonalizability.

(Refer Slide Time: 10:30)

Diagonalizability

Let T be a linear operator on the finite dimensional vector space V , we say that T is diagonalizable if there exists a basis for V , each vector of which is a characteristic (eigen) vector of T .

i.e. there exists a basis $S = \{u_1, u_2, \dots, u_n\}$ of V for which

$$\begin{aligned} T u_1 &= \lambda_1 u_1 \\ T u_2 &= \lambda_2 u_2 \\ &\dots\dots\dots \\ T u_n &= \lambda_n u_n \end{aligned}$$

then, T is represented by the diagonal matrix $D = \text{diag}(\lambda_1, \lambda_2, \dots, \lambda_n)$.

5

So, if T is A linear operator on a finite dimensional vector space V then we say that T is diagonalizable if there exist a basis for, each vector of which is a characteristic vector of T . So, what does it mean? It means that there exist a basis S which is given by u_1, u_2 , up to u_n of V , for which T of u_1 equal to $\lambda_1 u_1$, it is something like $A x$ equals to λx . You we already know that every linear transformation correspond to a matrix respect to some basis.

So, if this is a basis and, so T of u_1 will be $\lambda_1 u_1$ T of u_2 will be $\lambda_2 u_2$ and so on T of u_n will be $\lambda_n u_n$, then T is represented by a diagonal matrix D which is given by this. So, what does this mean we will discuss later on by taking any example of matrices?

(Refer Slide Time: 11:28)

Continued...

The linear operator T is diagonalizable if the matrix representation of T is similar to a diagonal matrix D .

i.e. $[T] \sim D \implies \exists$ an invertible matrix P such that $[T] = PDP^{-1}$.

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 6

So, the linear operator T is diagonalizable if the matrix representation of T that we already know that every linear transformation represent a matrix ok. So, if a linear transformation if a matrix representation of a linear operator T , is similar to a diagonal matrix D then we say that T is diagonalizable that clearly means that.

The matrix representation of T similar to D ; that means, there exists an invertible matrix P again such that such that matrix representation of T is equal to PDP inverse.

(Refer Slide Time: 12:11)

$A \sim D = \text{diag}(a_1, a_2, \dots, a_n) \implies \exists$ invertible matrix P s.t.

$$AP = PD$$

or

$$A = PDP^{-1}$$

(

$$A \rightarrow \lambda_1, \lambda_2, \dots, \lambda_n$$
$$D = \begin{pmatrix} \lambda_1 & 0 & \dots & 0 \\ 0 & \lambda_2 & \dots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & \dots & \dots & \lambda_n \end{pmatrix}$$

So, what we have concluded we have concluded suppose we have a matrix A which is a matrix correspond to a linear operator matrix representation of a linear operator T . Then we say that this matrix is diagonalizable if it is similar to a diagonal matrix D , D is a diagonal matrix ok. Diagonal $d_1 d_2$ up to d_n if A is n cross n matrix ok. It is similar to a diagonal matrix means they are exist an invertible matrix P ok. Invertible matrix P such that AP is equal to a PD or A is equals to $PD P^{-1}$.

Now, we know that eigenvalues of A and eigenvalues of its similar matrices are eigenvalues of similar matrices are same this we have already proved ok. So, an it is a diagonal matrix and the eigenvalues of diagonal matrix are nothing, but the diagonal element itself. So, we can say that that here the diagonal elements of this D are nothing, but eigenvalues of A ; that means, if A has an eigenvalues $\lambda_1 \lambda_2$ up to λ_n then this D will be nothing, but $\lambda_1 0 0 0 0 \lambda_2 0 0 0$ and 0 up to λ_n , because similar matrices have same eigenvalues now if characteristic polynomial.

(Refer Slide Time: 13:58)

Theorem

Suppose characteristic polynomial $P(\lambda)$ of T is a product of n distinct linear factors say

$$P(\lambda) = (\lambda - a_1)(\lambda - a_2)\dots(\lambda - a_n)$$

then, T is diagonalizable.

IIT ROORKEE NPTL ONLINE CERTIFICATION COURSE 7

$P(\lambda)$ of T or of A is a product of n distinct linear factors like this $\lambda^n - a_1 \lambda^{n-1} + \dots + (-1)^n a_n$, all have a power 1, all have a power 1, then T is always diagonalizable. If it is a distinct linear factors are all have a power 1 in the characteristic polynomial then T is a matrix is always diagonalizable, now let us discuss algebraic and geometric multiplicity of a eigenvalue and eigenvector. So, what is it mean let us discuss ok.

(Refer Slide Time: 14:35)

$$\begin{aligned} A_{5 \times 5} &\rightarrow \underline{\underline{(\lambda-1)^1}} (\lambda-2)^3 (\lambda+1) \\ &\quad \downarrow \\ &\quad \text{(k)} \\ G.M.(\lambda) &\leq A.M.(\lambda) \\ \text{For } \lambda=1 & \\ G.M.(\lambda=1) &\leq 1 \\ \text{For } \lambda=2 & \\ G.M.(\lambda=2) &\leq 3 \\ &\downarrow \\ &1, 2, 3 \end{aligned}$$

Suppose A is a 5 cross 5 matrix and its characteristic polynomial is $(\lambda-1)(\lambda-2)^3(\lambda+1)$. So, it is $(\lambda-1)^1(\lambda-2)^3(\lambda+1)$. Now corresponding to $\lambda=1$ there is only 1 factor. So, we can say that algebraic multiplicity for $\lambda=1$ is 1. Algebraic multiplicity means number of times that λ repeats. This $\lambda=1$ is repeating only 1 time.

So, algebraic multiplicity corresponding to $\lambda=1$ is 1, now this $\lambda=2$ is repeating 3 times. So, we say that algebraic multiplicity corresponding to $\lambda=2$ is 3 again this $\lambda=-1$ is repeating 1 time. So, we can say that algebraic multiplicity for $\lambda=-1$ is 1. So, algebraic multiplicity corresponding to a λ is nothing, but number of times that λ repeats. Now corresponding to this λ , $\lambda=1$ or $\lambda=2$, suppose $\lambda=2$ correspond $\lambda=2$ number of linearly, linearly independent eigenvectors are suppose k of course, k will be less than equal to 3 ok.

Now, suppose number of linearly independent eigenvectors corresponding to this $\lambda=2$, are k so this k is called geometric multiplicity for $\lambda=2$, geometric multiplicity corresponding to $\lambda=2$. So, geometric multiplicity is nothing, but number of linearly independent eigenvector corresponding to a λ ok. Now, geometric multiplicity which is G.M. correspond to a λ is always less than equal to algebraic multiplicity correspond to that λ , it cannot be more than this.

Now, since lambda equal to 1 is repeating 1 time, so what is algebraic multiplicity for lambda equal to 1 is 1 ok, for lambda equal to 1 for this particular example. So, G M for lambda equal to 1 will be less than equal to 1. So, G M will be 1 only it cannot be 0, there is at least one linearly independent eigenvector correspond to a lambda ok.

So, that means, if a lambda is repeating only 1 time, so number of linearly independent eigenvector correspond to that lambda will be 1 only; now here for lambda equal to 2 algebraic multiplicity is 3. So, what should be the geometric multiplicity, geometric multiplicity will be less than equal to 3 because by this property we can say that for lambda equal to 2, geometric multiplicity for lambda equal to 2 will be less than equal to algebraic multiplicity which is 3.

So, geometric multiplicity of correspond lambda equal to 2 either is 1 2 or 3 and for lambda equal to minus 1 geometric multiplicity is 1 ok. Now, what is a sufficient by which we can surely say that matrix is diagonalizable or not, because findings such P always for a bigger matrix say 10 cross 10 or 5 cross 5 is not an easy task. So, what should be the sufficient condition by which we can surely say seeing a matrix the whether it is diagonalizable or not. So, what is that condition let us discuss here these are this is a example you see.

(Refer Slide Time: 18:31)

Algebraic Multiplicity

The algebraic multiplicity of λ is defined to be multiplicity of λ as a root of characteristic polynomial say $P(\lambda)$.

Example: Let $P(\lambda)$ for any matrix of order 7×7 is $(\lambda - 2)(\lambda - 3)^2(\lambda + 5)^4$ then
 A.M. of $(\lambda = 2) = 1$
 A.M. of $(\lambda = 3) = 2$
 A.M. of $(\lambda = -5) = 4$

Geometric Multiplicity

The geometric multiplicity of an eigenvalue λ is the number of linearly independent eigenvectors associated with it. That is, it is the dimension of the nullspace of $A - \lambda I$. Therefore, if r is the rank of $A - \lambda I$ then number of linearly independent eigen vectors corresponding to λ are $n - r$, where n is the order of the matrix A .

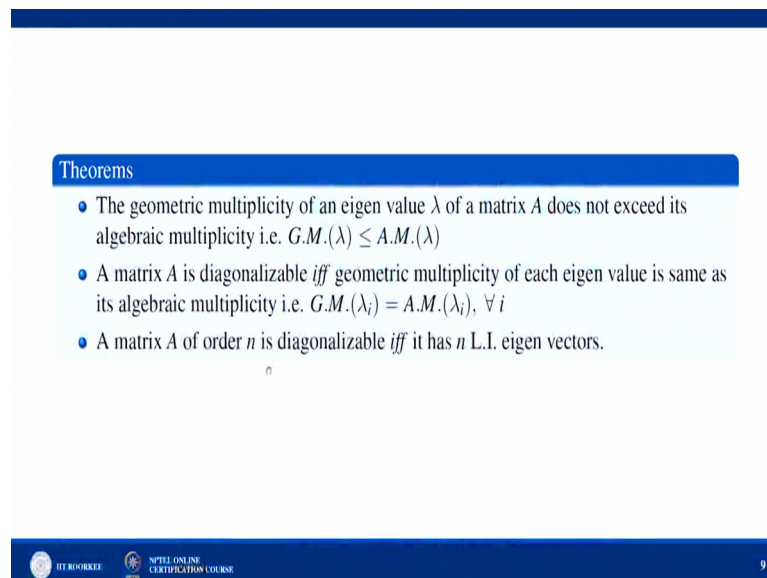

8

Here is a 7 cross 7 matrix here it is lambda minus 2 lambda minus 3 whole square lambda plus 5 whole is of 4. So, for lambda equal to 1 algebraic multiplicity is 1 for

lambda equal to 3 algebraic multiplicity is 2 for lambda equal to minus 5 algebraic multiplicity is 4 geometric multiplicity is 4.

Geometric multiplicity is simply number of linear independent eigenvector associated with the with it, that is it is the dimension of the null space of $A - \lambda I$, how it is we will discuss by an example.

(Refer Slide Time: 19:05)

The slide is titled "Theorems" and contains the following text:

- The geometric multiplicity of an eigen value λ of a matrix A does not exceed its algebraic multiplicity i.e. $G.M.(\lambda) \leq A.M.(\lambda)$
- A matrix A is diagonalizable iff geometric multiplicity of each eigen value is same as its algebraic multiplicity i.e. $G.M.(\lambda_i) = A.M.(\lambda_i), \forall i$
- A matrix A of order n is diagonalizable iff it has n L.I. eigen vectors.

At the bottom of the slide, there are logos for "IIT ROORKEE" and "NPTEL ONLINE CERTIFICATION COURSE" and the number "9".

So, this we have already seen that geometric multiplicity of an eigenvalue lambda does not exceed its algebraic multiplicity number 1. Now, a matrix is diagonalizable if and only if geometric multiplicity corresponding to each lambda is same as its algebraic multiplicity ok; that means, if geometric multiplicity corresponding to each lambda i is equal to algebraic multiplicity then only matrix will be diagonalizable.

So, this is a sufficient condition, or we can say that if a matrix as an order n then it will be diagonalizable if and only if it has n linearly dependent eigenvectors because, corresponding to each lambda geometric multiplicity equal to algebraic multiplicity number of number of number of linearly number of eigenvalues are total n . So, it must have n linearly independent eigenvector if matrix diagonalizable otherwise it is it will not be diagonalizable. So, let us discuss these two example quickly and from here we can analyze each and everything, so what is the first example.

(Refer Slide Time: 20:19)

$$A = \begin{pmatrix} 3 & -1 & 1 \\ 7 & -5 & 1 \\ 6 & -6 & 2 \end{pmatrix}, \quad \text{e-values: } 2, -4, x$$

$$2 + (-4) + x = \text{trace}(A) = 3 - 5 + 2$$

$$\Rightarrow x - 2 = 0 \Rightarrow x = 2$$

e-values: $\underbrace{2, 2}_{\text{algebraic}}, -4$

e-vector for $\lambda = 2$

$$(A - \lambda I)X = 0 \Rightarrow (A - 2I)X = 0 \Rightarrow \begin{pmatrix} 1 & -1 & 1 \\ 7 & -7 & 1 \\ 6 & -6 & 0 \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \\ x_3 \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \\ 0 \end{pmatrix}$$

$$\sim \begin{pmatrix} 1 & -1 & 1 \\ 0 & 0 & -6 \\ 0 & 0 & -6 \end{pmatrix} X = 0$$

$$\sim \begin{pmatrix} 1 & -1 & 1 \\ 0 & 0 & -6 \\ 0 & 0 & 0 \end{pmatrix} X = 0$$

$$x_1 - x_2 + x_3 = 0$$

$$-6x_3 = 0 \Rightarrow x_3 = 0$$

$$\Rightarrow x_1 = x_2, \quad x_3 = 0$$

$$\begin{pmatrix} x_1 \\ x_1 \\ 0 \end{pmatrix} = x_1 \begin{pmatrix} 1 \\ 1 \\ 0 \end{pmatrix}$$

The first example is you see a is given to us as 3 minus 1 1 7 minus 5 1 6 minus 6 2, eigenvalues which is given to us r 2 minus 4 and x ok. It is given to us or we can find out the eigenvalues by finding the characteristic polynomial of this matrix. Now, how you can find out x? We can find out because the sum of eigenvalues is equal to trace of A and trace of A is simply 3 minus 5 plus 2 ok. So, it will be x minus 2 will be equal to it is 5 minus 5 0 that is x equal to 2.

So, what are the eigenvalues of this A eigenvalues of A will be 2 2 minus 4 because x is 2. So, what is algebraic multiplicity of 2 is 2 and what is the algebraic multiplicity of minus 4 is 1, corresponding to lambda equal to minus 4 geometric multiplicity will be 1 only, because geometric multiplicity is always less than equals to algebraic multiplicity. Now correspond to lambda equal to 2 if geometric multiplicity is equal to 2, then only this matrix will be diagonalizable. If it is less than 2 that is 1 then this matrix is not diagonalizable, now diagonalizable means they are weak they are does not exist any D such that a similar to S, that does not exist any P such that A P equal to P D.

So, let us find eigenvector correspond to lambda equal to 2, so eigenvector for lambda equal to 2. So, how you will find it a minus lambda i x equal to 0 this implies lambda is 2. So, put it 2 this implies what is a minus 2 i it is 1 minus 1 q it is a 7 minus 7 1 ok. It is 6 minus 6 and 0 times x is means x 1 x 2 x 3. So, 0 means 0 0 0 now you can it is 1 minus 1 1 you can take, 1 operation that is this minus 7 time this is 0, this 1 is 7 time this

is 0 this 1 is 7 time this is minus 6. This minus 6 time this is 0 this minus 6 time this is 0 this minus this time minus 6, and this minus this minus this row will give 0 here, we are trying to make echelon form of this.

So, what we have obtained from here it is $x_1 - x_2 + x_3 = 0$ and $-6x_3 = 0$. So, this implies $x_3 = 0$ if you substitute $x_3 = 0$ here, so we obtain $x_1 = x_2$. So, how many linearly independent eigenvector correspond to $\lambda = 2$ it is only 1, which is $\begin{bmatrix} x_1 \\ x_1 \\ 0 \end{bmatrix}$ or $\begin{bmatrix} 1 \\ 1 \\ 0 \end{bmatrix}$ you taken any 1 linearly independent eigenvector which is you say $\begin{bmatrix} 1 \\ 1 \\ 0 \end{bmatrix}$.

So, so it is a only $\begin{bmatrix} 1 \\ 1 \\ 0 \end{bmatrix}$ only 1 that is geometric multiplicity corresponding to $\lambda = 2$ is 1 it should be 2 for diagonalizability, so we can say that this matrix A is not diagonalizable. So, how we can how we can check you see you see we have find the null space of this basically $A - \lambda I$, we have basically finding all this things means we have find null space of this matrix $A - 2I$ ok, or we can say that if r is the rank of the use rank of this matrix is 2 ok, and number of unknowns are 3 or order of matrices 3.

So, $3 - 2 = 1$ and 1 is the number of linear independent eigenvectors so; that means, if r is the rank of $A - \lambda I$ and n is the n is the order of A then $n - r$ will be the geometric multiplicity corresponding to that λ . And if it is equal to geometric if it is equal to algebraic multiplicity for each λ then only matrix will be diagnosable ok, now you can see here.

(Refer Slide Time: 25:17)

Examples

- Let $A = \begin{bmatrix} 3 & -1 & 1 \\ 7 & -5 & 1 \\ 6 & -6 & 2 \end{bmatrix}$. Given that eigen values of A are 2, -4 and x . Find x . Also verify whether A is diagonalizable or not.
- $B = \begin{bmatrix} 4 & 1 & -1 \\ 2 & 5 & -2 \\ 1 & 1 & 2 \end{bmatrix}$. Let the eigen values of A are 3, 3 and λ .
 - Find λ .
 - Evaluate L.I. eigen-vectors corresponding to 3 and λ .
 - Show that A is diagonalizable.
 - Find A^{10} and e^A .

ITR ROORKEE NPTEL ONLINE CERTIFICATION COURSE 10

You can see a second example here.

(Refer Slide Time: 25:21)

$A = \begin{pmatrix} 4 & 1 & -1 \\ 2 & 5 & -2 \\ 1 & 1 & 2 \end{pmatrix}$, e-values 3, 3 and λ

$3+3+\lambda = 4+5+2$
 $\lambda = 11-6 = 5$

$\lambda \rightarrow 3, 3, 5$

for $\lambda=3$: $(A-3I)X=0 \Rightarrow \begin{pmatrix} 1 & 1 & -1 \\ 2 & 2 & -2 \\ 1 & 1 & -1 \end{pmatrix} X=0 \sim \begin{pmatrix} 1 & 1 & -1 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix} X=0$

$x_1 = \begin{pmatrix} -1 \\ 0 \\ 1 \end{pmatrix}, x_2 = \begin{pmatrix} 1 \\ 0 \\ 1 \end{pmatrix}$ $x_1+x_2-x_3=0$

$\lambda=5$: $(A-5I)X=0 \Rightarrow \begin{pmatrix} -1 & 1 & -1 \\ 2 & 0 & -2 \\ 1 & 1 & -3 \end{pmatrix} X=0 \Rightarrow X = \begin{pmatrix} 1 \\ 2 \\ 1 \end{pmatrix}$

Here A is 4 1 minus 1 2 5 minus 2 1 1 2 and here eigenvalues are 3 3 and lambda, let us see whether it is diagonalizable or not and if yes what will be P and how we can find the other expressions in this problem ok.

So, this is a problem let us let us try to find it quickly, so the sum of eigenvalues again is equal to trace of A . So, lambda will be it is 9 plus 2 11 11 minus 6 that is 5, so we can say that eigenvalues of this A are 3 3 and 5. So, we will find number of linearly

dependent eigenvector correspond lambda equal to 3 first we will check ok. So, for lambda equal to 3, so for lambda equal to 3 it is A minus 3 I times x equal to 0 and this implies $\begin{pmatrix} 1 & 1 & -1 \\ 2 & 2 & -2 \end{pmatrix} x = 0$ and it is $\begin{pmatrix} 1 & 1 & -1 \\ 0 & 0 & 0 \end{pmatrix} x = 0$.

So, when we convert into basically echelon forms we can easily see that it is 2 times this and it is 1 time this. So, it is $\begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix} x = 0$, so what is the rank of this matrix rank is 1 and what is the order of the matrix is 3×3 minus 1 that is 2; that means, 2 is the geometric multiplicity corresponding to lambda equal to 3. So, yes because algebraic multiplicity is 2 and geometric multiplicity is also 2 for lambda equal to 5 it is 1 only so; that means, this matrix is diagonalizable ok. So, what are what are those 2 vectors x_1 plus x_2 minus x_3 equal to 0. So, we can to pick any 2 arbitrary linear depend eigenvector satisfying this equation.

So, we can take x_1 as $\begin{pmatrix} 1 \\ -1 \\ 0 \end{pmatrix}$ because $\begin{pmatrix} 1 \\ -1 \\ 0 \end{pmatrix}$ is satisfying this and x_2 as $\begin{pmatrix} 1 \\ 0 \\ 1 \end{pmatrix}$ and these two are linearly independent is it ok, because $\begin{pmatrix} 1 \\ -1 \\ 0 \end{pmatrix}$ satisfying this and $\begin{pmatrix} 1 \\ 0 \\ 1 \end{pmatrix}$ also satisfying this and these two are linearly independent. So, yes they will they will form the entire eigen space. Now, corresponding to lambda equal to 5, for lambda equal to again we can find out A minus A minus I times x equal to 0 and when we simplify it is $\begin{pmatrix} 2 & 0 & 0 \\ 0 & 2 & 0 \\ 0 & 0 & 5 \end{pmatrix} x = 0$. And when you simplify this you will get x as $\begin{pmatrix} 1 \\ 2 \\ 1 \end{pmatrix}$ you can find its echelon form and then vector you find it this vector.

(Refer Slide Time: 28:42)

$$P = \begin{pmatrix} x_1 & x_2 & x_3 \\ 1 & 1 & 1 \\ -1 & 0 & 2 \\ 0 & 1 & 1 \end{pmatrix}, \quad P^{-1} = \frac{1}{2} \begin{pmatrix} 2 & 0 & -2 \\ -1 & -1 & 3 \\ 1 & 1 & -1 \end{pmatrix}$$

$$AP = PD \Rightarrow A = PD^{-1} \quad D = \begin{pmatrix} 3 & 0 & 0 \\ 0 & 3 & 0 \\ 0 & 0 & 5 \end{pmatrix}$$

$$A^2 = A \cdot A = (PD^{-1})(PD^{-1})$$

$$= PD(P^{-1}P)D^{-1} = PD^2D^{-1}$$

$$\vdots$$

$$A^k = PD^kD^{-1}, \quad A^{10} = PD^{10}D^{-1} \quad D^{10} = \begin{pmatrix} 3^{10} & 0 & 0 \\ 0 & 3^{10} & 0 \\ 0 & 0 & 5^{10} \end{pmatrix}$$

$$A^{10} = PD^{10}D^{-1}$$

So, how you can find out P because it is diagonalizable now we have ensured that this matrix is diagonalizable. So how you can find out that P? So, to find P, to find P how you can find out P we simply write first x_1 vector here x_2 vector here x_3 eigenvector here. So, what is x_1 eigenvector; x_1 eigenvector we have already found $1 -1 0$ x_2 is $1 0 1$ and $1 2 1$ this will be that P and it is always invertible, because eigenvectors are linearly independent ok. So, it is always invertible ok. So, what will be P this inverse, so P inverse you can easily find out and the P inverse which you can find will be $2 0 -2$ $-1 -1 1$ $1 -1 1$ this you can find out the P inverse.

Now, A P, so AP will be equal to PD PD and this implies A is equal to PDP inverse. So, and what is D here D, will be nothing, but what is the first eigenvector first eigenvector is this x and this is corresponding to lambda equal to this corresponding lambda equal to 3 ok. So, here you can write first is $0 3 0 0 0$ the second eigenvector is corresponding to again lambda equal to 3 see ok.

So, it is $3 0$ and the third eigenvector is called you know 5. So, it is 5 now suppose if you want to find out A square say A square is nothing, but A into A which is equal to PDP inverse into PDP inverse and this is nothing, but PDP inverse P into D into P inverse. So, it is a PD square P inverse; that means, that means A square is also diagonalizable ok.

Similarly, if you proceed like this, so what is A raised to power k it is PD raised to power k into P inverse, suppose you want to find out A raised to the power 10. So, it is PD raised to power 10 into P inverse, and what is d raised to power 10 it is 3 raised to power 10 $0 0 0 3$ raised to the power 10 $0 0 0 3$ raised to power 10 $0 0 0 5$ raised to power 10 P you know P inverse you know D D raised to power 10 you know. So, simply multiplication of these three matrices will give you A raised to the power 10 which is otherwise we have to find out A raised to power 10 by 10 matrix multiplication suppose you want to find A raised to power 50.

Similarly, you can find out A raised to power 50 also P D raised to power 50 into P inverse, similarly by the matrix multiplication of these three now suppose, suppose you want to find out e raised to power A.

(Refer Slide Time: 31:26)

$$\begin{aligned}
 e^A &= I + \frac{A}{1!} + \frac{A^2}{2!} + \dots & A &= P D P^{-1} \\
 P^{-1} e^A P &= P^{-1} P + \frac{P^{-1} A P}{1!} + \frac{P^{-1} A^2 P}{2!} + \dots & & \sin(A) \\
 & & & \cos(A) \\
 &= I + \frac{D}{1!} + \frac{D^2}{2!} + \dots = e^D \\
 \Rightarrow e^A &= P e^D P^{-1} & e^D &= I + \frac{D}{1!} + \frac{D^2}{2!} + \dots \\
 &= \begin{pmatrix} e^{\lambda_1} & 0 & 0 \\ 0 & e^{\lambda_2} & 0 \\ 0 & 0 & e^{\lambda_3} \end{pmatrix} & & = I + \frac{\begin{pmatrix} \lambda_1 & 0 & 0 \\ 0 & \lambda_2 & 0 \\ 0 & 0 & \lambda_3 \end{pmatrix}}{1!} + \frac{\begin{pmatrix} \lambda_1^2 & 0 & 0 \\ 0 & \lambda_2^2 & 0 \\ 0 & 0 & \lambda_3^2 \end{pmatrix}}{2!} + \dots \\
 & & & = \begin{pmatrix} e^{\lambda_1} & 0 & 0 \\ 0 & e^{\lambda_2} & 0 \\ 0 & 0 & e^{\lambda_3} \end{pmatrix}
 \end{aligned}$$

It is I plus A plus A square by 2 factorial and so on ok. So, if you multiply P you see here it is A A equal to PDP inverse ok. So, here A equal to A is equal to PDP inverse, so if you if you take P inverse e raised to power P into P. So, this will be P inverse P plus P inverse A P upon factorial 1 plus P inverse A square P upon factorial 2 and so on. And this is identity plus it is D because A is invertible, I mean A is diagonalizable and it is D square upon factorial 2 as we have already discussed

So, it is e raised to power D, so what we have concluded that e raised to power A is nothing, but P e raised to power D into P inverse and how P is P be know P inverse be know how we can find e raised to power D, e raised to power D is nothing, but I plus D upon factorial 1 plus D square upon factorial 2 and so on. D is nothing, but here it is lambda 1 0 0 lambda 2 0 0 0 lambda 3 yeah here lambda 2 and lambda 2 are 3 and lambda 3 is 5 for this particular problem ok.

Now, square will be lambda 1 square 0 0 0 lambda 2 square 0 0 0 lambda 3 cube square upon factorial 2 and so on. So, when you club all these terms, so it is the first term is 1 plus lambda 1 upon factorial 1 lambda 1 square upon factorial 2 lambda 1 cube upon factorial 3 and so on, which is nothing, but e raised to power lambda 1 second term is 0 throughout this is 0 this again e raised to power lambda 2 0 0 0 e raised to the power lambda 3.

So, e^{tD} we can simply find out $e^{\lambda t}$ $\begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & e^{2\lambda t} & 0 & 0 \\ 0 & 0 & e^{3\lambda t} & 0 \\ 0 & 0 & 0 & e^{5\lambda t} \end{pmatrix}$. So, in this case e^{tD} will be what $e^{3\lambda t}$ $\begin{pmatrix} 3 & 0 & 0 & 0 \\ 0 & 3 & 0 & 0 \\ 0 & 0 & 3 & 0 \\ 0 & 0 & 0 & 3 \end{pmatrix}$. So, hence we can find out e^{tA} also e^{tA} power of a matrix by simply multiplying these three matrices. Similarly, if you want to find out $\sin A$ $\cos A$ of a matrix this is a matrix not an angle that also we can find out doing the same derivation same lines following the same lines similarly \cos of a matrix this also we can find out.

So, these are some of the applications of diagonalizability. If a matrix is diagonalizable we can easily find out higher powers of A by the multiplication of only three matrices e^{tA} or $\sin A$ $\cos A$ or other expressions of the similar types. So, in this lecture we have seen that when a matrix is diagonalizable what are important properties of the diagonalizability and, what are the some, some applications of a diagonal matrices.

Thank you.
