Lecture – 20
Gram Schmidt Process

Hello, friends. Welcome to lecture series on Matrix Analysis with Applications. So, today lecture is Gram Schmidt process, what Gram Schmidt process is and how it is used to find an orthogonal set of vectors.

(Refer Slide Time: 00:40)

Orthogonal set

A subset $\{v_1, v_2, \dots, v_n\}$ of a vector space V , with the inner product $\langle \cdot, \cdot \rangle$ is called orthogonal if $\langle v_i, v_j \rangle = 0$ when $i \neq j$ i.e. the vectors are mutually perpendicular.

Examples

- The set $\{(-1, 1, 0), (1, 1, 0), (0, 0, 1)\}$ is an orthogonal set.
- The set $\{(1, 2), (-2, 2)\}$ is not an orthogonal set.

IT Roorkee NPTEL ONLINE CERTIFICATION COURSE 2

So, first let us understand let us recall our definition orthogonal set. We know that if a subset v_1, v_2 up to v_n of a vector space V with inner product defined like this is called an orthogonal, if inner product of v_i, v_j is equal to 0 when i is not equal to j , that is for any two distinct vectors in this set any two distinct vector in this set are orthogonal I mean are perpendicular.

(Refer Slide Time: 01:23)

$$\left\{ \begin{array}{ccc} (-1, 1, 0), & (1, 1, 0), & (0, 0, 1) \\ v_1 & v_2 & v_3 \end{array} \right\}$$
$$\langle v_1, v_2 \rangle = -1 + 1 + 0 = 0, \quad \langle v_2, v_3 \rangle = 0, \quad \langle v_1, v_3 \rangle = 0$$
$$\langle v_i, v_j \rangle = 0, \quad i \neq j$$

For example, you see this set if you see this set if you take the inner product of these two say the set is simply you see the set is minus 1, 1, 0 then 1, 1, 0 then 0, 0, 1. Suppose, this is v_1 this is v_2 this is v_3 . You take the inner product of v_1 and v_2 the usual inner product. The usual inner product between two vectors in real dimensional vector space is simply the standard dot product. So, it would be a dot product of these two vectors.

So, minus 1 into 1 is minus 1, 1 into 1 is 1 and 0 into 0 is 0 which is 0. Similarly, you take inner product of v_2 and v_3 , it is simply you take 1 into 0 is 0, 1 into 0 is 0 and 0 into 1 is 0, so, it is 0. Similarly, inner product inner product of v_1 and v_3 is also 0. You can easily verify this is minus 1 into 0 is 0, 1 into 0 is 0 and 0 into 1 is 0. So, it is also 0. So, we can say that v_i and v_j for i is equal to 0 for i not equal to j . So, means this vector is this set of vector is I mean orthogonal.

Now, if you take the inner product between these two vectors it is minus 2, plus 4 which is 2, which is not equal to 0; that means, this set is not an orthogonal set.

(Refer Slide Time: 02:43)

Orthonormal set

An orthogonal set S is said to be an orthonormal set if $\|\alpha\| = 1 \forall \alpha \in S$ i.e. it is the set of mutually perpendicular vectors, each having length 1.

Examples

- 1 The standard basis of either \mathbb{R}^n or \mathbb{C}^n is an orthonormal set with respect to the standard inner product.
- 2 The set of vectors $\{(1, 0, -1), (1, \sqrt{2}, 1), (1, -\sqrt{2}, 1)\}$ is not an orthonormal set in \mathbb{R}^3 with respect to standard inner product.
- 3 Let V be the space of real valued continuous functions on the interval $0 \leq x \leq 1$ with the inner product

$$\langle f, g \rangle = \int_0^1 f(x)g(x)dx.$$

Let $f_n(x) = \sqrt{2} \cos 2\pi nx$ and $g_n(x) = \sqrt{2} \sin 2\pi nx$. The set $\{1, f_1, g_1, f_2, g_2, \dots\}$ is an orthonormal set.

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 3

Now, beside an orthogonal set if it also satisfy that norm of each vector is 1; norm means, how we define a norm of vector?

(Refer Slide Time: 02:59)

$$\|v\| = \sqrt{\langle v, v \rangle}$$
$$\{v_1, v_2, \dots, v_n\} = \begin{cases} \langle v_i, v_j \rangle = 0 & i \neq j \\ \langle v_i, v_i \rangle = 1 & \forall i \end{cases}$$
$$\langle v_i, v_j \rangle = \begin{cases} 0 & i \neq j \\ 1 & i = j \end{cases}$$
$$S = \{ (1, 0, 0, \dots, 0), (0, 1, 0, \dots, 0), \dots, (0, 0, \dots, 0, 1) \}$$

↳ orthonormal set.

Norm is simply if we want to define norm then norm of a vector v is nothing, but under root of inner product of v with itself this is simply a length of a vector or a norm of a vector. So, if we have a set of vector say v_1, v_2 up to say v_n so, this set is called an ortho normal set, if inner product of v_i, v_j is 0 for i not equal to j and inner product of v_i for v_i is equal to 1, for all i . Or, we can say that inner product of v_i, v_j is equal to 0 for

i not equal to j n is equal to 1 for i equal to j and if it holds for all i and j then the set of vectors are called orthonormal set.

So, suppose we have various examples to verify that the set of vectors are an orthonormal sets. Suppose, you have a standard basis of \mathbb{R}^n , if you have a standard basis of \mathbb{R}^n what are standard basis of \mathbb{R}^n ? We know standard basis of \mathbb{R}^n is simply $(1, 0, \dots, 0)$ and so on up to $(0, 1, 0, \dots, 0)$ and so on up to $(0, 0, \dots, 1)$. If you take the inner product of any two distinct vectors in this set so, it is 0. You can simply verify $(1, 0, \dots, 0) \cdot (0, 1, 0, \dots, 0) = 0$. So, you can simply verify that if you take inner product of any two distinct vectors in this set it is 0 and the norm of this any vector in this set any vector is 1. So, we can say that this set of vectors are is orthonormal set.

Similarly, if you take the second example, now second example is not an orthonormal you see. If you take the inner product of these two it is $(1, 0, \dots, 0) \cdot (1, 0, \dots, 0) = 1$, $(1, 0, \dots, 0) \cdot (0, \sqrt{2}, \dots, 0) = 0$, $(-1, 0, \dots, 0) \cdot (1, 0, \dots, 0) = -1$, which is 0. The inner product of these two is 0. If you verify the inner product of these two it is $(1, 0, \dots, 0) \cdot (1, -2, \dots, 1) = 0$. If we verify the inner product of first vector and the third vector it is $(1, 0, \dots, 0) \cdot (1, 0, \dots, -1) = 0$; that means, this set of vectors is orthogonal.

Now, the norm of this now the norm of this vector is under root 2 which is not 1; that means, this set of vectors is orthogonal, but not orthonormal.

(Refer Slide Time: 05:57)

$$\begin{aligned} \{v_1, v_2, \dots, v_n\} &\rightarrow \text{orthogonal set} \\ \left\{ \frac{v_1}{\|v_1\|}, \frac{v_2}{\|v_2\|}, \dots, \frac{v_n}{\|v_n\|} \right\} &\rightarrow \text{orthonormal set} \\ \downarrow \\ u_1 & \\ \|u_1\| = \left\| \frac{v_1}{\|v_1\|} \right\| &= \frac{1}{\|v_1\|} \|v_1\| = 1 \end{aligned}$$

So, how can we construct an orthonormal set from an orthogonal set you simply divide each vector by its norm. You see if you have a set of vectors like this say v_1, v_2 and so on up to v_n , and it is you know that this set is an orthogonal set. Orthogonal means that inner product of any two distinct vector is 0, and now you want to construct an orthonormal set from this set.

So, how you can do that? You can simply divide each vector by its norm. You see v_1 upon norm of v_1, v_2 upon norm of v_2 and v_n upon norm of v_n , it will be some different set from this set, but it will be an orthonormal set. So, always we can construct an orthonormal set from an orthogonal set by dividing each vector with its norm. You can easily verify now you see that norm of each vector is 1 now, what is the norm of the first vector if it is U_1 , what is the norm of U_1 ? Norm of U_1 is norm of v_1 upon norm of v_1 , it is a scalar quantity. So, we can take it out it is 1 upon norm of v_1 , norm of v_1 . So, it is 1.

Similarly, we can verify for these vectors also and if you take any two distinct vector in this set because norm is only a scalar quantity it will take out it will come out from the inner product and this set is an orthogonal set. So, this will also be an orthogonal.

Now, similarly if you take the third example where V is a space of real valued continuous functions on the interval x varying from 0 to 1 with the inner product defined like this, where f_n is defined like this is $\frac{1}{\sqrt{2}} \cos \frac{\pi}{2} \pi n x$ and g_n is this then this set is an orthonormal set, it is very easy to show.

(Refer Slide Time: 07:59)

$$\begin{aligned}
 f_i(x) &= \sqrt{2} \cos 2\pi i x, & g_j(x) &= \sqrt{2} \sin 2\pi j x \\
 \langle f_i, g_j \rangle &= \int_0^1 f_i(x) g_j(x) dx, & i \neq j \\
 &= 2 \int_0^1 \cos 2\pi i x \sin 2\pi j x dx \\
 &= 2 \int_0^1 \left(\sin(2\pi(j+i)x) + \sin(2\pi(j-i)x) \right) dx \\
 &= -\left(\frac{\cos 2\pi(j+i)x}{2\pi(j+i)} \right) \Big|_0^1 - \left(\frac{\cos 2\pi(j-i)x}{2\pi(j-i)} \right) \Big|_0^1 \\
 &= 0 \\
 \langle f_i, f_i \rangle &= 1, & \langle g_j, g_j \rangle &= 1 & \langle f_i, g_j \rangle &= 0 \quad \forall i \neq j
 \end{aligned}$$

You can take you can take any two you see you take $f_i(x)$; $f_i(x)$ is simply under root 2 $\cos 2\pi i x$ you take $g_j(x)$ $g_j(x)$ is simply under root 2 $\sin 2\pi j x$ and if you take the inner product of f_i with g_j which is given by a 0 to 1 $f_i(x)$ into $g_j(x)$ I am taking i naught equal to j here.

So, it will be equal to 0 to 1, if you take these two it is 2 times $\cos 2\pi i x$ into $\sin 2\pi j x dx$ and when you take 2 times when you take simply you see it is 2 of $\sin a x$ into $\cos b x$ which is 0 to 1 $\sin \sin a + b$ that is 2π will come out $j + i$ times x minus $\sin a - b$ $2 \sin a \cos b$. So, it is plus and it is 2π and it is $j - i$ times x whole dx and when you take the when you take the integration it is simply minus \cos of $2\pi(j+i)x$ upon $2\pi(j+i)$ plus \cos of $2\pi(j-i)x$ upon $2\pi(j-i)$ from 0 to 1, again it is minus $\cos 2\pi(j+i)$ minus $\cos 2\pi(j-i)$ plus $\cos 0$ minus $\cos 0$ all divided by $2\pi(j+i)$ minus $2\pi(j-i)$ which is 0.

Now, when you take x equal to 1 it is 2 multiple of 2π and \cos multiple of 2π is 1 and again from the lower limit also it is 1. So, $1 - 1$ is 0. Here also because by the same result it is 0. So, $0 - 0$ is 0 and similarly, we can verify that inner product of f_i with itself is one and similarly inner product of g_j which itself is 1, this we can easily verify using the same concept.

So, we can say that this set this set is an orthonormal set because if you take any two different vectors any two different functions. In fact, if you take one function as 1 and you multiply with any f_i , I mean I want to say in the same if you take inner product of 1

with f_i this is also 0 for all i and inner product of one with g_j is also 0 for all j this also we can verify using the same definition of inner product. So, hence we can say that this set is an orthonormal set.

(Refer Slide Time: 10:56)

Theorem

Let V be an inner product space and $S = \{v_1, v_2, \dots, v_k\}$ be an orthogonal subset of V consisting of non-zero vectors.

- 1 Then, S is L.I.
- 2 If $y \in \text{span}(S)$, then

$$y = \sum_{i=1}^k \frac{\langle y, v_i \rangle}{\|v_i\|^2} v_i$$

IIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 4

Now, the next result is let V be an inner product space, and the set which is given as v_1, v_2 up to v_k be an orthogonal subset of V consisting of non-zero vectors it is it is an orthonormal orthogonal subset and it consist of non-zero vectors. So, the first result is this set is always LI; that means, set of non-zero vectors which is an orthogonal is always linearly independent. How we can show this?

(Refer Slide Time: 11:25)

$$\begin{aligned} \{v_1, v_2, \dots, v_k\} &\rightarrow \text{orthogonal} \rightarrow \langle v_i, v_j \rangle = 0 \quad \forall i \neq j \\ &\quad v_i \neq 0 \quad \forall i \\ v &= \alpha_1 v_1 + \alpha_2 v_2 + \dots + \alpha_k v_k = 0 \\ \langle \alpha_1 v_1 + \alpha_2 v_2 + \dots + \alpha_k v_k, v_i \rangle &= \langle 0, v_i \rangle = 0, \quad \text{for any } 1 \leq i \leq k \\ \underbrace{\alpha_1 \langle v_1, v_i \rangle}_0 + \underbrace{\alpha_2 \langle v_2, v_i \rangle}_0 + \dots + \underbrace{\alpha_k \langle v_k, v_i \rangle}_0 &= 0 \\ \alpha_i \|v_i\|^2 = 0 &\Rightarrow \alpha_i = 0 \\ \alpha_1 = \alpha_2 = \dots = \alpha_k = 0 \\ \Rightarrow \text{LI} \end{aligned}$$

Very easy to show; you see we have the set v_1, v_2 up to v_k . It is given to us that the set is orthogonal orthogonal means inner product of v_i with v_j is 0 for all i not equal to j . Now, in order to show that this set is and we also know that v_i is not equal to 0 for all i because it consist of non-zero vectors.

Now, in order to show that this set is linearly independent, take a linear combination of these vectors, put it equal to 0 and try to show that each scalars are 0 ok. So, take a linear combination of these vectors, and put it equal to 0. Now, we have to show that each alpha is 0 in order to show that this set is linearly independent.

Now, say this vector is v the linear combination of these vectors say the linear combination of these vector is v which is of course, equal to 0. Now, you take the inner you take the inner product of this v with say any v_i or what you can do you take the inner product of this vector v with any v_i inner product of $\alpha_1 v_1$ plus $\alpha_2 v_2$ and so on up to $\alpha_k v_k$ with any say v_i here also 0 with v_i for any i any i from 1 to k . This i may be 1, this i may be 2 or this i may be k .

Now, this is of course, 0 inner product of 0 with any vector is always 0. Now, when you take the inner product definition of inner product of on this v_i ; so, this will be α_1 times inner product of v_1 with v_i plus α_2 times inner product of v_2 with v_i and so on. In between you will get some α_i also we are we are having v_i, v_i and plus and

so on α_k will come out inner product of v_k with v_i and which is which is equal to 0 which is equal to 0 because the right hand side is 0.

Now, since this is an orthogonal set that means, for any two distinct vectors in this set the inner product is 0. So, that means, this is 0 ; that means, this is 0 ; that means, this is 0 if i is not equal to k it will be, it will be it will have some value only when this i is equal to i . So, that means, it is α_i times norm of v_i square equal to 0 because all others are 0 and since v_i is not 0, for all i this means this is not equal to 0, and; that means, α_i equal to 0.

Now, you vary α you vary i , this i may be 1; that means, α_1 is equal to 0, this i may be 2; that means, α_2 equal to 0 and if you vary this i over k , so; that means, that means, α_1 equal to α_2 equal to and so on, α_k equal to 0 and this means set are set is linearly independent. Or you can understand it is like this you take you take the linear combination of this vector and suppose it is V you first take the inner product of this vector with v_1 this will give α_1 equal to 0.

Now, you take the inner product of this vector v with v_2 this will give α_2 equal to 0 and similarly, you will take inner product of this v with α_k this with α_k equal to 0 and hence we will obtain all α_i are equal to 0 that mean the set is linearly independent.

The second the second point is the second part of the theorem is if y belongs to span of S span means some linear combination of these vectors of S then y can be expressed as this sum also it is also easy to show you see.

(Refer Slide Time: 15:49)

$$\begin{aligned}
 & y \in \text{span} \{v_1, v_2, \dots, v_k\} \\
 \Rightarrow & y = \beta_1 v_1 + \beta_2 v_2 + \dots + \beta_k v_k \\
 & \langle y, v_p \rangle \quad 1 \leq p \leq k \\
 & = \langle \beta_1 v_1 + \dots + \beta_k v_k, v_p \rangle \\
 & = \beta_1 \langle v_1, v_p \rangle + \beta_2 \langle v_2, v_p \rangle + \dots + \beta_p \langle v_p, v_p \rangle + \dots + \beta_k \langle v_k, v_p \rangle \\
 & = \beta_p \|v_p\|^2 \\
 \Rightarrow & \beta_p = \frac{\langle y, v_p \rangle}{\|v_p\|^2} \\
 & y = \sum_{p=1}^k \beta_p v_p = \sum_{p=1}^k \frac{\langle y, v_p \rangle}{\|v_p\|^2} v_p.
 \end{aligned}$$

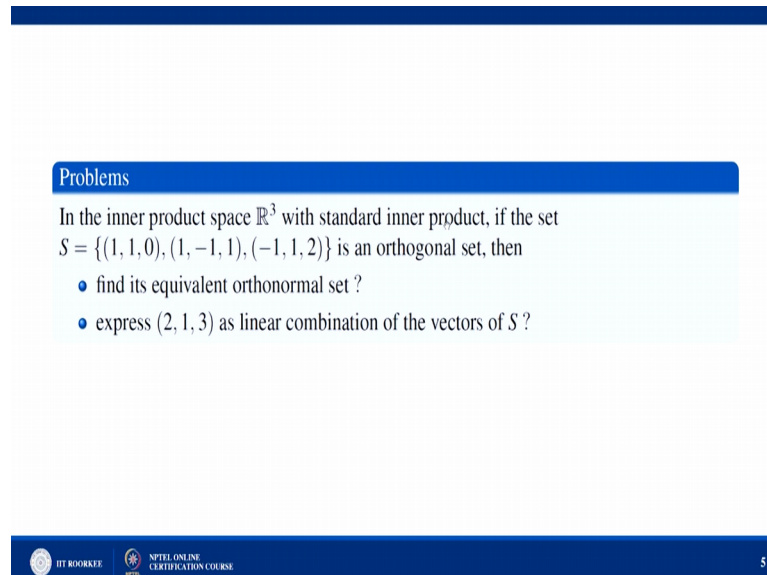

Now, this y belongs to span of this span of S . S is what? S is v_1, v_2 up to v_k . If this y belongs to span of this means there will exist some scalars such that y can be expressed as linear combination of those scalars with these vectors ok; that means, this implies that y will be equals to some $\beta_1 v_1$ plus $\beta_2 v_2$ and so on up to $\beta_k v_k$ because this y is in the span of these vectors. So, now, we have to find out β_1, β_2 up to β_k like this we have to find out.

Now, if you take inner product of this y with suppose v_p ok, where p is where p is any value between k and 1 again p may be 1 , may be 2 , may be k any p then this is equal to inner product of $\beta_1 v_1$ and so on up to $\beta_k v_k$ with v_p . Now, applying the definition of inner product this is β_1 inner product of v_1 with v_p plus β_2 inner product of v_2 with v_p plus and so on, β_p inner product of v_p with v_p plus and so on, in β_k inner product of v_k with v_p and since this set is an ortho orthogonal set so, all these terms are 0 only this term left. So, this means this is equals to β_p into norm of v_p square. So, that means, β_p is nothing, but inner product of y with v_p upon norm of v_p square.

So, what is β_1 ? You replace p by 1 . What is β_2 ? You replace p by 2 and similarly other β s. So, what we can say about y ? Now, this y can be written as summation p from 1 to k $\beta_p v_p$. So, this can be written as p from 1 to k β_p is inner product of y

with \sqrt{p} up on norm of \sqrt{p} square times \sqrt{p} . So, hence we obtain this. So, the same result instead of I am having \sqrt{p} no problem with that.

(Refer Slide Time: 18:37)

Problems

In the inner product space \mathbb{R}^3 with standard inner product, if the set $S = \{(1, 1, 0), (1, -1, 1), (-1, 1, 2)\}$ is an orthogonal set, then

- find its equivalent orthonormal set?
- express $(2, 1, 3)$ as linear combination of the vectors of S ?

ITB ROORKEE NPTEL ONLINE CERTIFICATION COURSE 5

Now, in this problem you see in the inner product space \mathbb{R}^3 with the standard inner product, this set is an orthogonal set. You can easily verify, you see you take the inner product of any two distinct vectors of this set you will find that it is 0. So, this set is an orthogonal set.

Now, how can we how we can find it is equivalent orthonormal set? This I have already discussed that in order to form an orthonormal set from an orthogonal set, simply divide each vector by its norm. So, what is the norm of this vector? It is under root 2, norm of this vector under root 3 norm of this vector is under root 1 plus 1 plus 4 that is under root 6.

(Refer Slide Time: 19:24)

$$S' = \left\{ \frac{(1, 1, 0)}{\sqrt{2}}, \frac{(1, -1, 1)}{\sqrt{3}}, \frac{(-1, 1, 2)}{\sqrt{6}} \right\}$$
$$(2, 1, 3) = \sum_{i=1}^3 \frac{\langle (2, 1, 3), v_i \rangle}{\|v_i\|^2} v_i$$

So, what is an equivalent orthonormal set of this the equivalent orthonormal set of this is suppose S' which is the first vector is $\frac{1}{\sqrt{2}}(1, 1, 0)$ upon under root the second vector is $\frac{1}{\sqrt{3}}(1, -1, 1)$ upon under root 3; the third vector is $\frac{1}{\sqrt{6}}(-1, 1, 2)$ upon under root 6. So, this will be an equivalent first element is $\frac{1}{\sqrt{2}}(1, 1, 0)$ the first element is $\frac{1}{\sqrt{2}}(1, 1, 0)$. So, this is an equivalent orthonormal set.

Now, again the next problem we have to express $(2, 1, 3)$ as the linear combination of vectors of S' . So, how can we can how we can express $(2, 1, 3)$ as a linear combination of elements of S' . So, we can use the previous result you see. In the previous result this set is an orthogonal set and if y belongs to span of S' then this y is some expression like this.

So, this so, here you can see that this because this is an orthogonal set and its and all vectors are linearly independent. So, this will be a basis of basis of \mathbb{R}^3 , any three linearly independent set of \mathbb{R}^3 will be a basis of \mathbb{R}^3 . So, this is a basis of \mathbb{R}^3 means this $(2, 1, 3)$ will belongs to span of this span of these three vectors v_1, v_2 and v_3 and since $(2, 1, 3)$ belongs to a span of these three vectors.

So, we can use the previous result sorry we can use a previous result here and this y we can write as like this y we can write it like this it is $\sum_{i=1}^3 \frac{\langle (2, 1, 3), v_i \rangle}{\|v_i\|^2} v_i$ here i from 1, 2, 3 because these are three vectors inner product of $(2, 1, 3)$ which is y with v_i 's upon norm of v_i 's square into v_i 's.

So, now, you vary now, you vary i here you can see in this example v_1 is this, v_2 is this, v_3 is this you can simply substitute in that expression to find out that to find out the expression in which v_1, v_2, v_3 can be expressed as linear combination of elements of or vectors of S .

(Refer Slide Time: 22:04)

Theorem

Suppose w_1, w_2, \dots, w_r form an orthogonal set of nonzero vectors in V . Let v be any vector in V . Define

$$v' = v - (c_1 w_1 + c_2 w_2 + \dots + c_r w_r)$$

where

$$c_1 = \frac{\langle v, w_1 \rangle}{\langle w_1, w_1 \rangle}, c_2 = \frac{\langle v, w_2 \rangle}{\langle w_2, w_2 \rangle}, \dots, c_r = \frac{\langle v, w_r \rangle}{\langle w_r, w_r \rangle}$$

Then v' is orthogonal to w_1, w_2, \dots, w_r .

NPTEL ONLINE CERTIFICATION COURSE
6

Now, the next result is supposed w_1, w_2 up to w_r form an orthogonal set of nonzero vectors in V , it is an orthogonal set again and if we write v which is an any vector in V and if we define v' as this where c_i is the defined like this expression, ortho orthano inner product of v with w_1 upon norm of w_1 square and similarly other c_i 's then this v' is always orthogonal to w again it is easy to show you see you see what is what is v' here you see.

(Refer Slide Time: 22:43)

$$v' = v - \sum_{i=1}^r c_i w_i, \quad c_i = \frac{\langle v, w_i \rangle}{\|w_i\|^2}$$

$$\langle v', w_i \rangle = 0 \quad \text{for all } i$$

$$\begin{aligned} \langle v', w_i \rangle &= \left\langle v - \sum_{i=1}^r c_i w_i, w_i \right\rangle \\ &= \langle v, w_i \rangle - \langle c_1 w_1 + c_2 w_2 + \dots + c_r w_r, w_i \rangle \\ &= \langle v, w_i \rangle - c_i \langle w_i, w_i \rangle \\ &= \langle v, w_i \rangle - \frac{\langle v, w_i \rangle}{\|w_i\|^2} \langle w_i, w_i \rangle \\ &= 0 \end{aligned}$$

What is v' here? v' is v minus the sum of $c_i w_i$ for i from 1 to r . So, you can take it up to r and sorry it is v and what are c_i 's? c_i 's are nothing, but these c_i 's are given to us that the c_i is inner product of v with w_i upon norm of w_i square and we have to show that this v' is orthogonal to w_1, w_2, \dots, w_r any w_i . So, that means, we have to show that this inner product of v' with any w_i is equal to 0 for all i , this we have to prove.

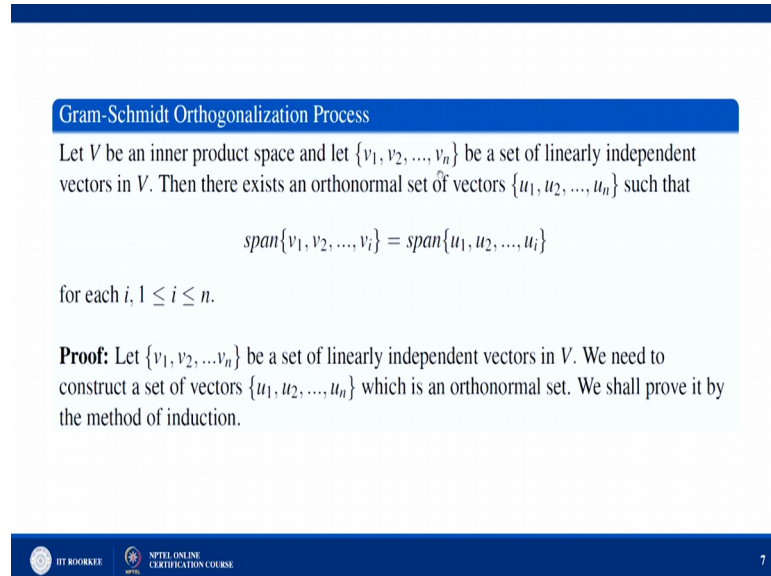

So, take the inner product of v' with w_i 's. This is inner product of what is v' ? v' minus some from i from 1 to r $c_i w_i$ with w_i . This is inner product of v with w_i minus. Now, when you open this sum it will be what? c_1 you see minus will come out its inner product of $c_1 w_1$ plus $c_2 w_2$ and so on up to $c_r w_r$ with w_i this will remain as it is.

Now, since this w_1, w_2 up to w_r is an orthogonal set; that means, w_1 with w_i is 0 if i is not equal to 1; that means, this will be having some nonzero value when w_i with inner product with w_i only; that means, it will value only one coefficient itself c_i , w_i with w_i . You see when you apply a definition of inner product in this expression w_1 inner product with w_i . So, in between we are having some $c_i w_i$ also. So, only that expression will be here all other for all other for other i 's it will be 0.

Now, this is v comma w_i 's minus c_i is given by this expression is given to us when you substitute it over here, and this cancels out and this is minus this is 0. So, we have shown that the inner product of v' with w_i is 0 for all i , because i is an arbitrary I mean you

can put it 1 or 2 or any i . So, hence we can we have shown that v_j is orthogonal to w_i 's.

(Refer Slide Time: 25:50)

Gram-Schmidt Orthogonalization Process

Let V be an inner product space and let $\{v_1, v_2, \dots, v_n\}$ be a set of linearly independent vectors in V . Then there exists an orthonormal set of vectors $\{u_1, u_2, \dots, u_n\}$ such that

$$\text{span}\{v_1, v_2, \dots, v_i\} = \text{span}\{u_1, u_2, \dots, u_i\}$$

for each $i, 1 \leq i \leq n$.

Proof: Let $\{v_1, v_2, \dots, v_n\}$ be a set of linearly independent vectors in V . We need to construct a set of vectors $\{u_1, u_2, \dots, u_n\}$ which is an orthonormal set. We shall prove it by the method of induction.

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 7

Now, we are having important process to orthogonalize the given set of vectors. Suppose a set of vectors v_1, v_2 up to v_n is a linearly independent set, and you want to find out an orthonormal or orthogonal anyone anything orthogonal orthonormal set of vectors u_1, u_2 , up to u_n such that the span of v_1, v_2 up to v_i is equal to span of u_1, u_2 up to u_i for each $i; i$ varying from 1 to n . So, this is basically this property or this result is called Gram Schmidt orthogonalization process.

Now, what is the proof of this? The proof is basically we can obtain the proof using mathematical induction. So, we have to construct a set of vectors u_1, u_2 up to u_n such that this set is an orthonormal set and the span of u_1, u_2 , up to u_i is equal to a span of v_1, v_2 up to v_i for each $i; i$ is varying from 1 to n this we have to show.

So, in the mathematical induction first we take i equal to 1, ok. First you take this i equal to 1 and then we take then we assume for i equal for this result for i hold for i minus 1 and try to show that it is also true for each i for i that means, we have done using mathematical induction.

(Refer Slide Time: 27:24)

$$\begin{aligned}
 \underline{i=1} \quad u_1 &= \frac{v_1}{\|v_1\|} & \|u_1\| &= 1 \\
 \|u_1\| &= \left\| \frac{v_1}{\|v_1\|} \right\| = \frac{1}{\|v_1\|} \|v_1\| = 1, \quad v_1 \neq 0 \\
 \|v_1\| &= \|v_1\| \|u_1\| \\
 \text{span}\{v_1\} &= \text{span}\{u_1\}
 \end{aligned}$$

$$\begin{aligned}
 \underline{i>1}, \quad \underline{i-1} \\
 w_i &= v_i - \langle v_i, u_1 \rangle u_1 - \langle v_i, u_2 \rangle u_2 - \dots - \langle v_i, u_{i-1} \rangle u_{i-1} \\
 u_i &= \frac{w_i}{\|w_i\|}, \quad w_i \neq 0 & \{u_1, u_2, \dots, u_{i-1}, u_i\} \\
 \langle u_i, u_p \rangle &= 0
 \end{aligned}$$

Now, for i equal to 1 we can easily see you see if we take i equal to 1. So, you can always set u_1 as v_1 upon norm of v_1 you have to set v_1 u_1 , u_2 up to u_n such that this set is an orthonormal set and the span of v_1, v_2 up to v_i is equal to span of u_1, u_2 up to u_i for each i . So, first we are taking i equal to 1 this is a first step for i equal to 1 I assume that u_1 is like this, of course, you can easily verify that norm of u_1 is 1 you can simply see the norm of this is what the norm of u_1 is what the norm of u_1 is the norm of v_1 upon norm of v_1 .

And norm is a scalar quantity it can be taken out norm of v_1 and which is 1 and of course, this norm is well defined I mean this v_1 is u_1 is well defined because v_1 is not equal to 0 because it is given to us that v_1, v_2 up to v_n is a linearly independent set and if any vector is 0 it will become LD set linearly independent set. So, that means ; that means, each v_i is not equal to 0. So, this expression this expression is well defined.

And, now, since v_1 equal to norm of v_1 times u_1 so, we can easily say that a span of v_1 is equal to a span of u_1 because it is some scalar multiplication of u_1 . So, is since is a scalar multiplication of u_1 . So, whatever span this v_1 is creating the same span will span by the vector u_1 . So, we have we have proved this result for i equal to 1.

No, we will assume that it hold for i equal to 1 say i minus 1 it holds for i , i equal to i minus 1. Now, we have to show that it also hold for i .

(Refer Slide Time: 29:28)

Continued...

Step 1: Let $i = 1$ and set $u_1 = \frac{v_1}{\|v_1\|}$ ($v_1 \neq 0$ as the set $\{v_1, v_2, \dots, v_n\}$ is linearly independent). Obviously, $\text{span}\{v_1\} = \text{span}\{u_1\}$ since $v_1 = \|v_1\|u_1$, that is, a scalar multiplication of u_1 . Also, $\|u_1\| = 1$. Hence, true for $i = 1$.

Step 2: Let $i > 1$. Suppose that we have constructed an orthonormal set of $i - 1$ vectors $\{u_1, u_2, \dots, u_{i-1}\}$ such that $\text{span}\{v_1, v_2, \dots, v_{i-1}\} = \text{span}\{u_1, u_2, \dots, u_{i-1}\}$. Now, since $\{v_1, v_2, \dots, v_n\}$ is linearly independent, therefore, $v_i \notin \text{span}\{v_1, v_2, \dots, v_{i-1}\}$. Now, define $w_i = v_i - \langle v_i, u_1 \rangle u_1 - \langle v_i, u_2 \rangle u_2 - \dots - \langle v_i, u_{i-1} \rangle u_{i-1}$ and set $u_i = \frac{w_i}{\|w_i\|}$, clearly $w_i \neq 0$. Therefore, $\|u_i\| = 1$. Further, we have to show that u_i is orthonormal to u_1, u_2, \dots, u_{i-1} . For any integer, $k, 1 \leq k < i$, consider

$$\langle u_i, u_k \rangle = \left\langle \frac{w_i}{\|w_i\|}, u_k \right\rangle$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 8

So, basically what I assumed in the step 2 that we have basically I have assumed that we have constructed an orthonormal set of i minus 1 vectors. u_1, u_2 up to u_{i-1} such that the span of these i minus 1 v 's is equal to a span of these u 's i minus 1 u 's.

Now, first of all since these vectors are linearly independent so, of course, any v_i 's cannot be expressed as linear combination of i minus 1 v 's. If it is not, then this v_i will if this v_i belongs to a span of this means this mean the set is linearly dependent, because this v_i belongs to span of this; that means, there exist a vector v_i in this set such that this that v_i can be expressed as linear combination of elements of this set. So, of course, this v_i will not belongs to span of this number one.

Now, we defined our self we defined w_i like this you see we defined w_i as we defined w_i as v_i minus inner product of v_i with u_1 times u_1 minus inner product of v_i with u_2 with u_2 and so on inner product of v_i with u_{i-1} times u_{i-1} because we are considering i minus 1 set of u 's. So, we have we our self have constructed a w_i satisfying this expression this we have constructed our self.

Now, we have constructed we have set u_i as a inner as a w_i upon norm of w_i . Now, again the norm of u_i is equal to 1 for each i that is easy to verify and again this expression is well defined because w_i is not equal to 0, because if w_i equal to 0; that means, v_i is equal to linear combination of u 's and linear combination of u 's u 's with i minus 1 vector is same as linear combination of v_i with i minus 1 vectors that may the

set v_1, v_2 up to v_n will become LD. So, which is not possible hence w_i will not equal to 0.

Now, now, we can now, we have to show that this set is an orthogonal set orthonormal set basically we have to show that this u_i is orthogonal to any u_p , where p is varying from 1 to i minus 1. So, the thing is very easy to show u_p or u_k you can take anything, where k is varying from 1 to i minus 1. Now, what is u_i here u_i is u_i is w_i upon norm of w_i , as we have already discussed. This expression of norm of w_i can be taken out by a definition of inner product can be taken out. This w_i is given by you can see here this w_i this expression we can substitute it here with u_k .

(Refer Slide Time: 33:03)

Continued...

$$\begin{aligned} \langle u_i, u_k \rangle &= \frac{1}{\|w_i\|} \langle w_i, u_k \rangle \\ &= \frac{1}{\|w_i\|} \langle v_i - \langle v_i, u_1 \rangle u_1 - \dots - \langle v_i, u_{i-1} \rangle u_{i-1}, u_k \rangle \\ &= \frac{1}{\|w_i\|} (\langle v_i, u_k \rangle - \langle v_i, u_k \rangle \|u_k\|^2) \\ &= \frac{1}{\|w_i\|} (\langle v_i, u_k \rangle - \langle v_i, u_k \rangle) \\ &= 0 \end{aligned}$$

Hence, $\{u_1, u_2, \dots, u_i\}$ is orthonormal. Also, $v_i \in \text{span}\{u_1, u_2, \dots, u_i\}$. Both the sets $\{v_1, v_2, \dots, v_i\}$ and $\{u_1, u_2, \dots, u_i\}$ are linearly independent, hence by induction

$$\text{span}\{u_1, u_2, \dots, u_i\} = \text{span}\{v_1, v_2, \dots, v_i\} \quad \forall 1 \leq i \leq n.$$

Now, u_1, u_2 up to u_i minus 1 is an orthogonal set i mean orthonormal set this is by our assumption assumption of mathematical induction. So, that means, if you take the inner product of v_i with u_k it will be remain as it is and this u_k for any k between 1 to i minus 1 this will this will be 0 for all u_i 's other than i equal to k .

Though it will exist only for i equal to k and for i equal to k the inner product of u_k with u_k will be norm of u_k square and it will v_i into u_k you see in some term you will be having some v_i u_k inner product of v_i with u_k with u_k . Now, a inner product of u_k with u_k will be norm of u_k square and this will come out since it is a orthonormal set. So, this norm is 1 and this will cancel out. So, it is 0.

So, we have shown that the set of now, i vectors u_1, u_2 up to u_i 's becomes an orthonormal set, we have set it like this only and also v_i belongs to span of this also we have seen from above. So, both the vectors are linearly independent. Hence by induction we can say that span of this equal to span of this for all i 's. So, hence we have proved Gram Schmidt process.

So, basically what in what happens in Gram Schmidt process that if you are having a any linearly independent set of vectors say u_1, u_2 up to u_k then you can always find an orthonormal or orthogonal set of vectors v_1, v_2 up to v_k such that span of u_i 's u_1, u_2 up to u_i is equals to a span of v_1, v_2 up to v_i for each i this is a main concept of Gram Schmidt process.

(Refer Slide Time: 35:20)

$$\begin{aligned} \{u_1, u_2, \dots, u_k\} &\rightarrow \text{LI} \\ &\rightarrow \{v_1, v_2, \dots, v_k\} \rightarrow \text{orthogonal} \end{aligned}$$

$$\begin{aligned} v_1 &= u_1 \\ v_2 &= u_2 - \frac{\langle u_2, u_1 \rangle}{\|u_1\|^2} u_1 & \langle v_1, v_2 \rangle &= \langle u_1, u_2 - \frac{\langle u_2, u_1 \rangle}{\|u_1\|^2} u_1 \rangle \\ v_3 &= u_3 - \frac{\langle u_3, u_1 \rangle}{\|u_1\|^2} u_1 - \frac{\langle u_3, u_2 \rangle}{\|u_2\|^2} u_2 & &= \langle u_1, u_3 \rangle - \frac{\langle u_2, u_1 \rangle}{\|u_1\|^2} \langle u_1, u_3 \rangle \\ &\vdots & &= \langle u_1, u_3 \rangle - \frac{\langle u_2, u_1 \rangle}{\|u_1\|^2} \langle u_1, u_3 \rangle \\ v_p &= u_p - \sum_{i=1}^{p-1} \frac{\langle u_p, u_i \rangle}{\|u_i\|^2} u_i & &= \langle u_1, u_p \rangle - \frac{\langle u_2, u_1 \rangle}{\|u_1\|^2} \langle u_1, u_p \rangle \\ & & &= 0 \end{aligned}$$

Now, how we can apply Gram Schmidt process in some in various problems? You see say u_1, u_2 up to u_k which is linearly independent given to you. Now, you want to construct an orthogonal set of vectors using Gram Schmidt process from this set of vectors. So, how we can do that? You so, suppose that set of vectors is v_1, v_2 , up to v_k of course, the same number of elements will be there.

So, we have to construct this orthogonal set. If you obtain orthogonal then orthonormal can be find out by dividing each vector by its norm, because all vectors will be definitely nonzero vectors because this vectors are linearly independent.

So, how we can find v_1 ; v_1 you take it equal to u_1 , v_2 will be equals to u_2 minus norm of u_2 with v_1 upon norm of u_1 square with u_1 . You can easily verify you can easily verify the norm of inner product of v_1 with v_2 will be 0 because inner product of v_1 with v_2 is what is u_1 with u_2 minus inner product of u_2 , u_1 upon norm of u_1 square with u_1 which is this into this inner product of u_1 , u_2 minus this quantity is I mean this quantity is a real quantity.

So, it can be taken out into inner product of u_1 with u_1 . So, this cancels out ok, this bar will be here, yeah. Here will be a bar because this scalar is coming from the second term. So, this is inner product of u_1 with u_2 and this we again u_1 with u_2 . So, this cancels out and this is 0. So, we can easily verify that we are hence we are constructing an orthogonal set of vectors.

Similarly, v_3 will be similarly u_3 minus inner product of u_3 with u_2 upon norm of u_2 square with u_2 minus inner product of u_3 with u_1 upon norm of u_1 square with u_1 . So, if you want to construct say v_p . So, v_p will be u_p minus i if varying from 1 to p minus 1 inner product of u_p with u_i upon norm of u_i square with u_i . So, in this way we can construct an orthonormal orthogonal set of vectors and if further we want to find orthonormal set of vector using this so, we can divide each vector by its norm.

(Refer Slide Time: 38:02)

Continued...

Corollary 1: Let V be a finite dimensional inner product space. Then V has an orthonormal basis.

Corollary 2: Let V be a finite dimensional inner product space. Then any orthonormal set of vectors $\{u_1, u_2, \dots, u_m\}$ in V can be extended to an orthonormal basis of V .

IIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 10

Now, these are some result from this if V be a finite dimensional inner product space then it has always having a orthonormal basis, very easy to show you see. If we are

having a finite dimensional vector space so, it will be having a finite basis, say it is u_1, u_2, \dots, u_n if it is having and if it is a finite dimensional vector space and using Gram Schmidt process we can always find an equivalent orthonormal set of vectors. So, that means, there exists an orthonormal basis of a finite dimensional vector space inner product space.

The next is if V is a finite dimensional inner product space then any orthonormal set of vectors any in V can be extended to form an orthonormal basis of V .

(Refer Slide Time: 39:04)

$$\{u_1, u_2, \dots, u_m\} \longrightarrow \{u_1, u_2, \dots, u_m, v_1, \dots, v_p\}$$

$$\{u_1, u_2, \dots, u_m, u_{m+1}, \dots, u_{m+p}\} \longrightarrow$$

If it is an orthonormal, if it is an orthonormal set of vectors if it is a orthonormal set of vectors you see this is an orthonormal set of vectors. So, we can always extend this to find an basis say to find an basis of V if basis dimension of basis is m plus p , and using using Gram Schmidt orthogonalization process we can always find its equivalent orthonormal basis using the corollary one. So, that means, u_1, u_2 up to u_m and it is u_m plus 1 and so on up to u_m plus p that will be the equivalent orthonormal orthonormal basis of that that finite dimensional vector space. So, these are few examples.

(Refer Slide Time: 39:53)

Example

- Apply the Gram-Schmidt orthogonalization process to find an orthogonal basis and then an orthonormal basis for the subspace U of \mathbb{R}^4 spanned by

$$u_1 = (1, 0, 1, 0), u_2 = (1, 1, 1, 1), u_3 = (0, 1, 2, 1)$$
- Let $V = P(\mathbb{R})$ with the inner product $\langle f(x), g(x) \rangle = \int_{-1}^1 f(t)g(t)dt$, and consider the subspace $P_2(\mathbb{R})$ with the standard ordered basis β . Use Gram-Schmidt process to replace β by an orthogonal basis $\{v_1, v_2, v_3\}$ for $P_2(\mathbb{R})$.

11

Based on this let us discuss the first one using the second one can be obtained similarly. So, what basically Gram Schmidt process is? You see you have given a set of linearly independent vectors and how to find an equivalent orthogonal or orthonormal set of vectors from it such that the span of u_1, u_2 up to u_i is equal to span of v_1, v_2 up to v_i for each i .

(Refer Slide Time: 40:31)

$$\{u_1, u_2, \dots, u_k\} \rightarrow \text{LI}$$

$$\hookrightarrow \{v_1, v_2, \dots, v_k\} \rightarrow \text{orthogonal}$$

$$v_1 = u_1$$

$$v_2 = u_2 - \frac{\langle u_2, v_1 \rangle}{\|v_1\|^2} v_1$$

$$v_3 = u_3 - \frac{\langle u_3, v_1 \rangle}{\|v_1\|^2} v_1 - \frac{\langle u_3, v_2 \rangle}{\|v_2\|^2} v_2$$

$$\vdots$$

$$v_p = u_p - \sum_{i=1}^{p-1} \frac{\langle u_p, v_i \rangle}{\|v_i\|^2} v_i$$

$$\langle v_2, v_1 \rangle$$

$$= \langle u_2 - \frac{\langle u_2, v_1 \rangle}{\|v_1\|^2} v_1, v_1 \rangle$$

$$= \langle u_2, v_1 \rangle - \frac{\langle u_2, v_1 \rangle \langle v_1, v_1 \rangle}{\|v_1\|^2} = 0$$

That means suppose you are having a set of vector say the set of vectors are v_1, v_2 or u_1, u_2 and so on up to u_k , these are linearly independent and you want to construct an

equivalent orthogonal set of vectors from this using Gram Schmidt orthogonalization process. So, suppose it is v_1, v_2 and so on up to v_k , number of elements will be same of course, so, that is orthogonal. These orthogonal set of vectors we want to construct from this.

So, how we will form it, how will how we will obtain this? You set v_1 is equal to u_1 . Now, v_2 can be obtained as v_2 minus inner product of u_2 with v_1 upon norm of v_1 square into v_1 you can easily verify you see in that proof also we are doing the same thing, but other way out, you see if you find the inner product of u_2 with v_2 with v_1 what is this? This is inner product of u_2 minus $u_2 \cdot v_1$ upon norm of v_1 square times v_1 with v_1 . So, this is inner product of u_2 with v_1 minus this is a scalar quantity will comes out by the definition of inner product and this is a inner product of v_1 with v_1 . So, this is a squares cancels out and this is 0.

Similarly, we can verify for others also. If you want to find v_3 this is v_3 minus inner product of u_3 with v_2 upon norm of v_2 square into v_2 minus inner product of u_3 with v_1 upon norm of v_1 square with v_1 it is v_2 and similarly, if you want to find say any v_p it is u_p minus summation i from 1 to $p-1$, inner product of u_p with v_i 's, norm of v_i is square times v_i 's.

So, this is how we can easily find out set of orthogonal vectors and once we obtain an orthogonal set of vectors from this linearly independent set using Gram Schmidt process so, orthonormal set can be find out by dividing each vector with it is norm.

So, now, let us discuss one example based on this before discussing an examples let us discuss these two results you see that if V ; V is a finite dimensional inner product space then V is an orthonormal basis you see if it has a finite dimensional inner product space; that means, it is having a finite dimensional basis and using Gram Schmidt process you can always find it is equivalent orthogonal orthonormal set which is of course, a basis because a span a span is equal a span of both the sides are equal by the Gram Schmidt process and is independent also. So, by the Gram Schmidt process we can always find an orthonormal basis of any finite dimensional inner product space V .

Now, if V is a finite dimension inner product space then any orthonormal set of vectors v_1, v_2, \dots, v_m can be extended to form an orthonormal basis of V .

(Refer Slide Time: 44:00)

$$\begin{aligned} \{u_1, u_2, \dots, u_n\} &\rightarrow \text{Orthonormal} \\ &\searrow \\ &\{u_1, u_2, \dots, u_m, v_1, \dots, v_p\} \\ &\quad \downarrow \\ &\{u_1, u_2, \dots, u_m, \underline{u_{m+1}}, \dots, u_{m+p}\} \end{aligned}$$

This is also very easy to show you see you are now having a set of vectors u_1, u_2, \dots, u_m . This is an orthonormal set. Now, you can always extend up any set to form the basis of V finite dimensional vector space V . So, suppose we extended it up to p suppose dimension of the vector space v is m plus p and now, using Gram Schmidt process Gram Schmidt orthogonalization process you can always convert this set of vectors into its equivalent orthonormal set of vectors. So, hence we have extended this orthogonal set to an orthogonal basis of this vector space V .

Now, these are some problems based on this and there are two problems that can be easily obtained. Let us discuss the first problem, the second can be solved on the same lines, the definition of inner product is different other things are same.

(Refer Slide Time: 45:13)

$$\begin{aligned} & \left\{ \begin{array}{ccc} (1, 0, 1, 0) & (1, 1, 1, 1) & (0, 1, 2, 1) \\ u_1 & u_2 & u_3 \end{array} \right\} \\ v_1 &= u_1 \\ v_2 &= u_2 - \frac{\langle u_2, v_1 \rangle}{\|v_1\|^2} v_1 \\ &= (1, 1, 1, 1) - \frac{2}{2} (1, 0, 1, 0) = (0, 1, 0, 1) \\ v_3 &= u_3 - \frac{\langle u_3, v_1 \rangle}{\|v_1\|^2} v_1 - \frac{\langle u_3, v_2 \rangle}{\|v_2\|^2} v_2 \\ &= (0, 1, 2, 1) - \frac{1}{2} (1, 0, 1, 0) - \frac{1}{2} (0, 1, 0, 1) \\ &= (0, 1, 2, 1) - (1, 1, 1, 1) \\ &= (-1, 0, 1, 0) \end{aligned} \quad \{u_1, u_2, u_3\} \rightarrow \text{orthogonal}$$

You see here we are having in this example you are having the set of vectors as 1, 0, 1, 0, the second is 1, 1, 1, 1, the third is 0, 1, 2, 1 this is u_1, u_2, u_3 . So, v_1 is equals to u_1 by the Gram Schmidt process, v_2 with be equals to u_2 minus inner product of u_2 with v_1 upon norm of v_1 square times v_1 which is 1, 1, 1, 1 minus; inner product of u_2 with v_1 is what? Is 1 plus 1, 2 upon norm of v_1 square, v_1 is u_1 and norm of this is 2 and v_1 is u_1 which is 1, 0, 1, 0. So, this is equals to basically 2, 2 cancels out it is 0, 1, 0, 1.

Now, if you take the inner product of this with v_1 ; v_1 is u_1 ; that means, 0 plus 0 plus 0 plus 0 which is 0. So, that means, we are going on the right direction, how we find v_3 now? v_3 is again u_3 minus inner product of u_3 with v_1 upon norm of v_1 square times v_1 minus inner product of u_3 with v_2 upon norm of v_2 square times v_2 . So, this is you see u_3 is 0, 1, 2, 1 minus.

Inner product of u_3 with v_1 u_3 with v_1 , v_1 is u_1 ; the inner product of u_3 with u_1 is 1 into 0 is 0 0 this is 2, this is 0, that is 2 inner product of v_1 square is again 2, v_1 is 1, 0, 1, 0 minus, inner product of u_3 with v_2 u_3 with v_2 v_2 is this vector. So, this is 0, this is 1, this is 0, this is 1, 1 plus 1 is 2 and norm of u_2 square, norm of u_2 square is again 2 and v_2 is 0, 1, 0, 1 this 2, 2 cancels out 2, 2 cancels out it is 0, 1, 2, 1 minus when you subtract these two it is 1, minus 1, 1, minus 1 and if you take the you have to add these two sorry. So, it is 1 this is a 0 plus 1 is 1, this is 1 plus 0 is 1, this is 1. Now, you subtract these two it is minus 1 it is 0, it is 1, it is 0. Now, if you take inner product

of these two, these two it is 0, 0, 0, 0 you have 0 inner product of these two is minus 1 plus 1, 0, yeah.

Now, this v_1, v_2, v_3 this set of vectors v_1, v_2, v_3 is an orthogonal set and if you want to find out the corresponding orthonormal set, then divide each vector by its norm. Norm of this is 2, norm of this is 2 and norm of this is also I mean norm of this is under root 2, norm of this is under root 2 and norm of this is also under root 2. So, divide each vector by its norm, you will get an equivalent orthonormal set of vectors. Now, similarly we can discuss this solve this examples.

So, hence we have seen this in this lecture that if we have a if you are given a set of a linear independent vectors how we can find it is in equivalent orthogonal or orthonormal set of vectors.

So, thank you.
