Lecture - 13
Solution of Non-Homogeneous Systems

Hello friends. Welcome to this lecture. In this lecture, we will continue our study of linear system and if you recall in previous 2 lectures, we have discussed the solution process of finding, finding solutions of the homogeneous linear differential equation. You can understand like this that in previous few classes, we have discussed $\dot{x} = A(t)x$. How to find out a solution of this and $\dot{x} = A(x)$.

(Refer Slide Time: 00:58)

So first we have discussed the existence and uniqueness criteria and then we have found the solution method to find out the fundamental matrix solution of these 2 system. So in this, this is corresponding to autonomous system, where this matrix A is not depending on time t, then we call the system as autonomous system, while this is system is called non-autonomous system and in the case when A is having n linearly independent Eigenvectors.

Then we know how to find out a solution and we have found the solution $x_i(t) = e^{\lambda_i t} v_i$ where $\lambda_i v_i$ are Eigen pair of the matrix A and when we are not able to find out n linearly independent Eigenvectors, then we have seen the process of finding the solution of

the form $e^{At}v$ and based on the type of V , we have found the solution using this concept and we have seen that how to calculate fundamental matrix solution $x(t)$.

Where $x(t)$ is nothing but $x_1(t)$ to $x_n(t)$ where each X_i is a solution of $\dot{x} = Ax$ and also for non-autonomous system also, we have discussed certain methods to find out the solution of this and we have also seen that in general this $e^{t_0-t} A ds$ will not work as a fundamental matrix of solution here. So here we have seen that under certain conditions as A and this matrix if they commute, then we can consider this as a say possible form of a solution of $\dot{x} = A(t)x$.

And we have seen certain other type of solution of $\dot{x} = A(t)x$. Now we will proceed further and now we will focus on non-homogeneous system of linear equation. Now consider the following linear non-homogeneous differential equation $\dot{x} = A(t)x + f(t)$.

(Refer Slide Time: 03:17)

The nonhomogeneous equation: variation of parameters

Now consider the following linear nonhomogeneous differential equation

$$\dot{x} = A(t)x + f(t) \quad \checkmark$$

*$x' = A(t)x$
 $\rightarrow x(t) = (x_1, \dots, x_n)^T$*

We try to find out a solution of the problem with the help of a fundamental set of solutions of the associated linear homogeneous differential equation. So far we have discussed some methods to find out a solution of a given linear homogeneous differential equation of the following type:

$$\dot{x} = A(t)x.$$

*$x(t) = X(t)C$
 $= c_1 x_1(t) + c_2 x_2(t) + \dots + c_n x_n(t)$*

Now, we may use the variation of parameter method to find the solution of the initial value problem

$$\dot{x} = A(t)x + f(t), \quad x(t_0) = x_0. \quad (2)$$

So the only is different from this 2 previous thing that here now we have one more term extra that is $f(t)$, which is known as forward term, external forward term, we can consider that. So if we have this system $\dot{x} = A(t)x + f(t)$, then we call this system as linear non-homogeneous differential equation and we try to find out a solution of the problem with the help of a fundamental set of solution of the associated linear homogeneous differential equation.

So to find out the solution of this, we consider the associated homogeneous linear system, that is $\dot{x} = A(t)x$ and then we know the fundamental matrix solution is already available that is $x_1(t)$ to $x_n(t)$. So once we have the fundamental matrix solution for homogeneous part, then we try to find out the solution for this linear non-homogeneous differential equation, okay. Now, so far we have discussed some method to find out a solution of a given linear homogeneous differential equation of the following type.

That is $\dot{x} = A(t)x$. Now we may use the variation of parameter method to find the solution of the solution of the initial value problem $\dot{x} = A(t)x + f(t)$ and $x(t_0) = x_0$. So what is variation of parameter method. If you recall, the general solution of $\dot{x} = A(t)x$ is written as $x(t) = x(t) * \text{matrix } C$ where C is or you can simply write it like $C_1 x_1(t) + C_2 x_2(t) + \dots + C_n x_n(t)$. Now here if you look at C_1, C_2 and C_n are all constant.

Now if you consider a very, or we can say that, you can take any arbitrary value of these constant and it will still serve as a solution. Now I can say that if $C_1, C_2,$ and C_n are variable constant or you can say the parameters, then this will act as a solution of, under certain condition this will act as a solution of the non-homogeneous problem. So it means that we are varying our parameters such that this will serve as a solution of non-homogeneous problem. We will try to understand what is, I mean through this.

(Refer Slide Time: 05:56)

$$\dot{x} = A(t)x$$

Let us assume that $x^1(t), \dots, x^n(t)$ forms a fundamental set of n (linearly independent) solutions of equation (1). Then the general solution of (1) is given by

$$x(t) = c_1 x^1(t) + \dots + c_n x^n(t), \quad \checkmark$$

where $c_i, i = 1, \dots, n$ are n real constants. \checkmark

Therefore we may assume that a solution of (2) is given in the form $\dot{x} = A(t)x + f(t)$

$$x(t) = u_1 x^1(t) + \dots + u_n x^n(t), \quad \checkmark \quad (3)$$

where $u_i, i = 1, \dots, n,$ are n parameters.

So here let us assume that $x_1(t)$ to $x_n(t)$ forms a fundamental set of n solution, fundamental set of n solution means that all these are linearly independent and they are solving the system $\dot{x} = A(t)x$, right. They are solution as well as they are linearly independent. Then the general solution of 1 is given as X_H , X_H here means homogeneous part, so the solution of homogeneous linear equation is given as $C_1x_1(t) + C_2x_2(t) + \dots + C_nx_n(t)$ here.

Where C_i i from 1 to n are n real constants. Now therefore, we may assume that a solution of 2 that is $\dot{x} = A(t)x + f(t)$, we may assume that it will be the form $x(t) = U_1x_1(t) + U_2x_2(t) + \dots + U_nx_n(t)$ here, where U_i are n parameters. So if you look at what is the difference between here and here, if you look at here, these C_1 to C_n are constant, but here your U_1 to U_n are parameters. So we are basically varying these parameters so that this term 3 will act as a solution of the non-homogeneous problem $\dot{x} = A(t)x + f(t)$. So just look at how this will work.

(Refer Slide Time: 07:25)

We may rewrite the above equation in the following matrix form

$$\dot{x}_{NH}(t) = X_H(t)u(t)$$

where $X_H(t)$ is a fundamental matrix solution given by $X_H(t) = [x^1(t), \dots, x^n(t)]$
and

$$u(t) = \begin{pmatrix} u_1(t) \\ \vdots \\ u_n(t) \end{pmatrix}$$

$$x' = A(t)x$$

So we may rewrite the above equation in the following matrix on that is $\dot{x}_{NH} = X_H \cdot U(t)$ where NH is the solution of non-homogeneous problem $\dot{x} = A(t)x + f(t)$ is the solution matrix or fundamental matrix solution given by this matrix $x_1(t)$ to $x_n(t)$. We are calling it fundamental because x_1 to x_n are given n linearly independent solution of $\dot{x} = A(t)x$. So it means that we are writing our solution of non-homogeneous problems as $X_H(t) \cdot U(t)$.

Now we need to find out the matrix $U(t)$, where $U(t)$ is given as $U_1(t), U_2(t), \dots, U_n(t)$, this is a column matrix where a component of column matrix $U_1(t)$ to $U_n(t)$, some unknown function, which we need to determine, so that this will act as a solution of non-homogeneous problem.

(Refer Slide Time: 08:21)

We may rewrite the above equation in the following matrix form

$$\underline{x_{NH}(t) = X_H(t)u(t)}$$

where $X_H(t)$ is a fundamental matrix solution given by $X_H(t) = [x^1(t), \dots, x^n(t)]$
and

$$u(t) = \begin{pmatrix} u_1(t) \\ \vdots \\ u_n(t) \end{pmatrix}$$

$$x' = A(t)x$$

So now using the expression of $x(t)$ in the differential equation $x' = A(t)x + f(t)$ and integrating between t_0 to t , we have the following formula. Let us try to understand that how we got this formula 4 here. So please look at here, the solution is this part, let me look at here. So here we have $x' = A(t)x$.

(Refer Slide Time: 08:45)

$$\begin{aligned}
 x' &= A(t)x, & x^1(t) & \dots & x^n(t) \\
 X(t) &= [x^1(t) \dots x^n(t)] \\
 X'(t) &= A(t)X(t) \\
 x_{nh} &= X(t)u(t) & U(t) &= \begin{bmatrix} u_1(t) \\ \vdots \\ u_n(t) \end{bmatrix} \\
 x' &= A(t)x + f(t) \\
 x'_{nh} &= \frac{X(t)u(t) + X(t)u'(t)}{1} = \frac{A(t)X(t)u(t) + f(t)}{1} \\
 \frac{A(t)X(t)u(t) + X(t)u'(t)}{1} &= \frac{A(t)X(t)u(t) + f(t)}{1} \\
 X(t)u'(t) &= f(t)
 \end{aligned}$$

And we have solutions $X_1(t)$ to say $X_{n1}(t)$, $X_{n2}(t)$ here. So here we have $X_1(t)$ to $X_{nt}(t)$. So with the help of these n linearly independent solution, we form matrix like $X_1(t)$, $X_{n2}(t)$, $X_{nt}(t)$, right. So it means that this will satisfy the following matrix differential equation $\dot{x}(t) = A(t)x(t)$ here. So here it is $n \times n$, here it is $n \times n$, here it is $n \times n$. Now we claim that this $X^{-1}(t) \dot{X}(t) = U(t)$ where $U(t) = U_1(t)$ to $U_n(t)$. These are some n function, which we need to find out and this is known $X(h)$.

Now let us try to find out this $U(t)$ such that this will act as a solution of $\dot{x}(t) = A(t)x(t) + f(t)$ here. Please note down this is $n \times 1$, this is $n \times n$, this is $n \times 1$, so let us verify here. So if it is a solution of this, it will satisfy this, so it means that let us find out $X^{-1}(t) \dot{X}(t) = U(t)$ and $U(t) + x(t) U'(t)$ and we want that it should be equal to your $A(t)$, X is here as $x(t)$ and $U(t) + f(t)$. So it means that we need to find out this $U(t)$ in a way such that $x'(t) = A(t)x(t) + f(t)$.

Which is coming out to be this must be equal to this. Now $x'(t)$, here it is XH . So here XH is a matrix solution of this matrix equation that is $\dot{x}(t) = A(t)x(t)$. So using this, we can write this as $A(t)X^{-1}(t)U(t) + X^{-1}(t)U'(t) = A(t)x(t)U(t) + f(t)$. Now if you look at this, these 2 are equal, so we can cancel out here and what is left here is $x'(t) - A(t)x(t) = f(t)$, but we are interested in finding this $U(t)$, so we can take.

Since $X^{-1}(t)$ is basically a fundamental matrix solution, so inverse exists, so we multiply by the inverse of this and we can write here as $X^{-1}(t) \dot{X}(t) = U(t)$ sorry $x(t)$ is here. Let me write it in a clear manner.

(Refer Slide Time: 11:46)

$$\begin{aligned}
U'(t) &= X_H^{-1}(t) f(t) \quad t_0 \\
U(t) - U(t_0) &= \int_{t_0}^t X_H^{-1}(s) f(s) ds \\
\checkmark U(t) &= U(t_0) + \int_{t_0}^t X_H^{-1}(s) f(s) ds \\
\checkmark X_{nh} &= X_H(t) U(t) \\
\boxed{X_{nh} &= X_H(t) U(t_0) + \int_{t_0}^t X_H(t) X_H^{-1}(s) f(s) ds} \\
X_{nh}(t_0) &= X_H(t_0) U(t_0) \\
\Rightarrow U(t_0) &= X_H^{-1}(t_0) X_{nh}(t_0)
\end{aligned}$$

So we can multiply by the inverse of this and we can have this $X_H^{-1}(t)$ inverse of $f(t)$, but since it is $U'(t)$, so let us integrate to find out $U(t)$, so let us integrate between t_0 to t where t_0 is initial point and t is some point lying in some interval. So this will, when we integrate we have $U(t) - U(t_0) = \int_{t_0}^t X_H^{-1}(s) f(s) ds$, right. So we need to find out $U(t)$, so $U(t)$ is basically $U(t_0) + \int_{t_0}^t X_H^{-1}(s) f(s) ds$.

Now $U(t)$ is known to us, so with the help of $U(t)$, now we can find out the solution of non-homogeneous problem that $x(t) = U(t)$. So this I can write it $x(t) = U(t_0) + \int_{t_0}^t x(t) X_H^{-1}(s) f(s) ds$, so $X_H^{-1}(t) x(t) = X_H^{-1}(t) U(t_0) + \int_{t_0}^t X_H^{-1}(t) X_H^{-1}(s) f(s) ds$. So this is the solution of non-homogeneous problem that is $X_H^{-1}(t) U(t_0) + \int_{t_0}^t X_H^{-1}(t) X_H^{-1}(s) f(s) ds$. The only problem is that what is the value of $U(t_0)$. So if you look I can use this equation to find out the value of $U(t_0)$.

You can find out $x(t_0) = X_H(t_0) U(t_0)$. So we can multiply by the inverse $X_H^{-1}(t_0)$ since X is a fundamental matrix solution, so inverse exist for all t , so in particular for t_0 also, so I can find out the value of $X_H^{-1}(t_0) x(t_0) = U(t_0)$ and we have, okay. So we can write this and we can have our solution like this.

(Refer Slide Time: 14:28)

$$x_{NH}(t) = X_H(t) X_H^{-1}(t_0) x_0 + \int_{t_0}^t X_H(t) X_H^{-1}(s) f(s) ds$$

$\checkmark x_{NH}(t_0) = ??$

$X_H(t) -$
 $X_H^{-1}(t) -$
 $X_H(t_0) =$

So $x_{NH}(t) = X_H(t)$, now X inverse t_0 and $X_{NH}(t_0)$ to t X_H inverse t . This is not inverse, it is $X_H(t)$ and X_H inverse as $f(s)d(s)$. Now it is written completely and so this will act as a, this is already known to us that $X_{NH}(t_0)$ is known to us. It is already given with the initial value problem. So this is known to us and if you are able to find out $X_H(t)$, then we can calculate X_H inverse of t also and we can calculate $X_H(t_0)$ also. So all these are calculable when $X_H(t)$ is known to us.

(Refer Slide Time: 15:38)

Using the expression of $X_H(t)$ in the differential equation $\dot{x} = A(t)x + f(t)$ and integrating between t_0 and t we have

$$x_{NH}(t) = X_H(t) X_H^{-1}(t_0) x_0 + X_H(t) \int_{t_0}^t X_H^{-1}(s) f(s) ds. \quad (4)$$

Since, for autonomous case, e^{At} may be taken as a fundamental matrix solution, then the equation (4) may be rewritten as

$$x(t) = e^{A(t-t_0)} x_0 + \int_{t_0}^t e^{A(t-s)} f(s) ds. \quad (5)$$

$X(t) = e^{At}$
 $X^{-1}(t) = e^{-At}$
 $X(t) X^{-1}(t) = e^{At} e^{-At} = e^0 = I$
 $X(t) X^{-1}(t_0) = e^{At} e^{-At_0} = e^{A(t-t_0)}$
 $X(t) X^{-1}(t_0) = e^{At} e^{-At_0} = e^{A(t-t_0)}$

NPTEL ONLINE CERTIFICATION COURSE

I can say that using the expression $X_H(t)$ in the differential equation $\dot{x} = A(t)x + f(t)$ and integrate between t_0 to t , we have the following formula $x_{NH}(t) = X_H(t) X_H^{-1}(t_0) x_0$ where x_0 is basically X_{NH} at t_0 . If you look at here, it is already given here that $x(t_0) = x_0$. So using

this, I can write this $X^{-1}(t_0)$ as $x_0 + X^{-1}(t)$ since this integration is respect to X , so I can take it out $X^{-1}(t)$ and we can write t_0 to t X^{-1} inverse as $\int_{t_0}^t f(s)ds$.

So is when X fundamental matrix solution of this system $\dot{X} = A(t)X$ is known to us, then we can write down the one particular solution of $\dot{x} = A(t)x + f(t)$ and it is given by equation number 4. Now since for autonomous case, we know one fundamental matrix solution given by e^{At} . So e^{At} may be taken as a fundamental matrix solution, then this equation number 4 may be written in this following manner $x(t) = e^{At-t_0}$.

This expression is I am using for $X^{-1}(t) X^{-1}(t_0)$. If you look at $x(t) = e^{At}$, then X^{-1} inverse of t , you can verify that it is nothing but e^{-At} that you can verify that $X^{-1}(t) X^{-1}(t_0) = e^{-At} e^{At-t_0}$ and $e^{-At} e^{At-t_0}$. Now since these 2 matrix commute with each other, so we can write this as $x(t) X^{-1}(t_0) = e^{-At} e^{At-t_0}$ that is $e^{-At} e^{At-t_0}$, this is nothing but identity. So this will act as an inverse matrix of this $x(t) = e^{At-t_0}$.

So once we know the inverse, then we can calculate $x(t) X^{-1}(t_0)$ that is nothing but $e^{At-t_0} e^{-At-t_0}$ and we can simply write e^{At-t_0} . Similarly, we can calculate $x(t) X^{-1}(s)$, this is nothing but $e^{At-t_0} e^{-As}$ that is e^{At-s} , that is what is written here. So I can say that a solution of non-homogeneous differential equation is given as $x(t) = e^{At-t_0} x_0 + \int_{t_0}^t e^{At-s} f(s)ds$.

So it means that we need to find out e^{At} for the homogeneous part, then we can write down the solution of non-homogeneous part using the equation number 5. Now once we have the formula with us, let us see some example and see how we can calculate this.

(Refer Slide Time: 18:43)

Example 1

Solve the following linear nonhomogeneous initial value problem

$$\dot{x} = \begin{pmatrix} 1 & 0 & 0 \\ 2 & 1 & -2 \\ 3 & 2 & 1 \end{pmatrix} x + \begin{pmatrix} 0 \\ 0 \\ e^t \cos 2t \end{pmatrix}, \quad x(0) = \begin{pmatrix} 0 \\ 1 \\ 1 \end{pmatrix}.$$

Solution If λ be an eigenvalue of $A = \begin{pmatrix} 1 & 0 & 0 \\ 2 & 1 & -2 \\ 3 & 2 & 1 \end{pmatrix}$. Then the characteristic equation of A is given by

$$|A - \lambda I| = \begin{vmatrix} 1-\lambda & 0 & 0 \\ 2 & 1-\lambda & -2 \\ 3 & 2 & 1-\lambda \end{vmatrix} = 0.$$

$x' = Ax + f(t)$
 $f(t) = \begin{pmatrix} 0 \\ 0 \\ e^t \cos 2t \end{pmatrix}$
 e^{At} $x' = Ax$

So let us consider the first example, solve the following linear non-homogeneous initial value problem $\dot{x} = \begin{pmatrix} 1 & 0 & 0 \\ 2 & 1 & -2 \\ 3 & 2 & 1 \end{pmatrix} x + \begin{pmatrix} 0 \\ 0 \\ e^t \cos(2t) \end{pmatrix}$ with initial condition that $x(0) = \begin{pmatrix} 0 \\ 1 \\ 1 \end{pmatrix}$. So I can write this as system $\dot{x} = A(x) + f(t)$ where A is the matrix given like this $\begin{pmatrix} 1 & 0 & 0 \\ 2 & 1 & -2 \\ 3 & 2 & 1 \end{pmatrix}$ and $f(t)$ I am writing this as $\begin{pmatrix} 0 \\ 0 \\ e^t \cos(2t) \end{pmatrix}$, okay. Now we need to calculate the fundamental matrix e^{At} .

So for that since it is a constant matrix, let us find out e^{At} with the help of fundamental matrix of solution. So for that we need to find out 3 linearly independent solution of $\dot{x} = Ax$. So for that let us first find out the Eigenvalues of the coefficient matrix A . So for that consider the characteristic equation of A that is determined of $A - \lambda I = 0$ that is $(1-\lambda)(1-\lambda-2)(1-\lambda-2) = 0$. When you simplify.

(Refer Slide Time: 20:08)

Or

$$(1-\lambda)[(1-\lambda)^2+4]=0.$$

$(1-\lambda)^2 = -4$
 $(1-\lambda) = \pm 2i$
 $\lambda = 1 \pm 2i$

Therefore Eigenvalues of A are given as $\lambda_1 = 1$ and $\lambda_{2,3} = 1 \pm 2i$.

Eigenvector corresponding to $\lambda_1 = 1$:

$$\begin{pmatrix} 1-1 & 0 & 0 \\ 2 & 1-1 & -2 \\ 3 & 2 & 1-1 \end{pmatrix} \begin{pmatrix} x_1 \\ y_1 \\ z_1 \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \\ 0 \end{pmatrix} \quad (A - \lambda_1 I) \vec{x} = 0$$

$\lambda_1 = 1$
 $\lambda_2 = 1+2i$
 $\lambda_3 = 1-2i$

On simplification, we have $\begin{pmatrix} x_1 \\ y_1 \\ z_1 \end{pmatrix} = \begin{pmatrix} 2 \\ -3 \\ 2 \end{pmatrix}$

$2x_1 - 2z_1 = 0$
 $3x_1 + 2z_1 = 0$
 $3z_1 + 2x_1 = 0 \Rightarrow z_1 = -\frac{3}{2}z_2$

$x_1 = z_1$
 $x_1 = -\frac{3}{2}z_2$

You will have the following expression that is $1-\lambda(1-\lambda)^2+4=0$. So this will give you a simple rule that is $\lambda=1$ and if you simplify this, this is what $1-\lambda^2+4\lambda-4=0$, but this is possible when λ take the complex value. So $1-\lambda = \pm 2i$. So $\lambda = 1 \pm 2i$. So we call this as λ_2, λ_3 that is $1 \pm 2i$ here. So if you look at $\lambda_1=1$, $\lambda_2=1+2i$ and $\lambda_3=1-2i$. So if you look at all 3 are distinct.

So it means that if all 3 are distinct, it means that we have guarantee of having 3 linearly independent Eigenvectors in this case and we can find out 3 linearly independent solutions and hence we can find out a fundamental matrix solution in a quite easy manner and so first find out the Eigenvector corresponding to $\lambda_1=1$. So for that, we need to solve this $(A-\lambda_1 I)\vec{x}=0$ here.

So here let us put $\lambda_1=1$ and try to solve here, where x is given as x_1, y_1 and z_1 . So it is the following equation $1-1 \ 0 \ 0 \ 2 \ 1 \ -1 \ -2 \ 3 \ 2 \ 1 \ -1 \ x_1 \ y_1 \ z_1 = 0 \ 0 \ 0$. So if you look at the first equation, first equation is nothing but $0=0$, so it will not give any equation in terms of x_1, y_1, z_1 . If you look at the second equation, it is $2x_1-2z_1=0$ and $3x_1+2z_1=0$. So if you look at here we can easily find out your x_1 as z_1 and with the help of x_1 , you can put it here.

And you can write it here $3z_1+2x_1=0$. So it means that x_1 is given as $-\frac{3}{2}z_1$, sorry z_1 here, sorry it is some problem here, it is y_1 it is basically. So it is $3x_1+2y_1$ and it is y_1 . So we can

write it $y_1 = -3/2x_1$, sorry $3/2z_1$. So now x_1 can be written as z_1 and y_1 can be written as $-3/2z_1$. So we can take some suitable value for z_1 . So let us take value $z_1 = 2$, then I can write y_1 as $-3/2 * 2$ that is -3 here and your x_1 is nothing but z_1 .

So Eigenvector is coming out to be x_1 that is 2, y_1 that is -3 and z_1 is 2. So $2 -3 2$ will be the corresponding Eigenvector and so we can find out linearly independent solution corresponding $\lambda_1 = 1$ as e to power $\lambda_1 t$.

(Refer Slide Time: 23:33)

Hence $x^1(t) = e^t \begin{pmatrix} 2 \\ -3 \\ 2 \end{pmatrix}$ ✓

Eigenvector corresponding to $\lambda_2 = 1 + 2i$: $(A - \lambda_2 I)X = 0$
 $\checkmark X = \begin{pmatrix} x_2 \\ y_2 \\ z_2 \end{pmatrix}$

$$\begin{pmatrix} 1 - (1 + 2i) & 0 & 0 \\ 2 & 1 - (1 + 2i) & -2 \\ 3 & 2 & 1 - (1 + 2i) \end{pmatrix} \begin{pmatrix} x_2 \\ y_2 \\ z_2 \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \\ 0 \end{pmatrix}$$

On simplification, we have $\begin{pmatrix} x_2 \\ y_2 \\ z_2 \end{pmatrix} = \begin{pmatrix} 0 \\ i \\ 1 \end{pmatrix}$ ✓

Thus $x(t) = e^{(1+2i)t} \begin{pmatrix} 0 \\ i \\ 1 \end{pmatrix}$

Handwritten notes:
 $-2i \ x_2 = 0 \Rightarrow x_2 = 0$
 $2x_2 - 2iy_2 - 2z_2 = 0$
 $2iy_2 = 2z_2$
 $iy_2 = z_2$
 $x_2 = 0$
 $y_2 = i$
 $z_2 = 1$

So e to power λ_1 , $\lambda_1 = 1$, so e to power t $2 -3 2$ is 1 linearly independent solution. So $x_1(t) = e$ to power t $2 -3 2$ is basically linearly independent solution of this. Now second thing is find out the Eigenvector corresponding to $\lambda_2 = 1 + 2i$ and we have already discussed this case that when we have complex Eigenvector case, then we have Eigenvalues comes in pairs and Eigenvector also comes in pairs.

So here we know that how to find out 2 solution out of this. So let us first find out Eigenvector corresponding to $\lambda_2 = 1 + 2i$. So we simply solve $A - \lambda_2 I$, your $x = 0$ here. Here x let us assume that it is x_2, y_2 and z_2 . We need to find out this x . So let us put the value of λ_2 that is $1 + 2i$, so we can have $1 - 1 + 2i$ 0 0 x_2 y_2 z_2 and so we can have this. Now when you simplify, then we have the following equation $-2i$ 0 0 and 2 here $-2i$ -2 3 2 $-2i$ x_2 y_2 z_2 and that is 0 0 0 .

So one thing is very much clear here that $-2I x_2=0$ means that your x_2 has to be 0. So if you look at the second equation is $2x_2 -2I y_2 -2z_2=0$. My x_2 is 0, so this part is gone, so we can write down $2I y_2=z_2$, yeah $-z_2$. So now I can put the value of y_2 or z_2 and we can find out the corresponding value of, so x_2 is 0. Now put y_2 as 1, so if you put $x_2=0$, and $y_2=1$, then z_2 you can find out as, it is $2I \cdot 1=-z_2$. So this is $2I$ square that is -2 and that minus will cancel out.

So z_2 will come out to be, I think there is something wrong here. It is $2z_2$ here, okay. So z_2 is coming out to be 1. So your $x_2 y_2 z_2$ is coming out to be 0 1 and 1. So solution, the complex solution will be given as $x(t)=e^{(1+2i)t} \begin{pmatrix} 0 \\ 1 \\ 1 \end{pmatrix}$ and when you solve, this is a complex valued solution and if you solve the other way around that is $1-2I$, then also you can find out the Eigenvector, just complex conjugate to this Eigenvector.

And will get a similar kind of solution for other one that is $1-2I$. So first find out the real and imaginary part of this complex valued solution.

(Refer Slide Time: 27:04)

Now

$$\begin{aligned}
 e^{(1+2i)t} \begin{pmatrix} 0 \\ i \\ 1 \end{pmatrix} &= e^t (\cos 2t + i \sin 2t) \left[\begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix} + i \begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix} \right] \\
 &= e^t \left[\cos 2t \begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix} - \sin 2t \begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix} \right. \\
 &\quad \left. + i \sin 2t \begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix} + i \cos 2t \begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix} \right] \\
 &= e^t \begin{pmatrix} 0 \\ -\sin 2t \\ \cos 2t \end{pmatrix} + i e^t \begin{pmatrix} 0 \\ \cos 2t \\ \sin 2t \end{pmatrix}
 \end{aligned}$$

$\lambda_1 = 1 + 2i$
 $\lambda_2 = 1 - 2i$
 $x_1 = e^{(1+2i)t} \begin{pmatrix} 0 \\ 1 \\ 1 \end{pmatrix}$
 $x_2 = e^{(1-2i)t} \begin{pmatrix} 0 \\ 1 \\ 1 \end{pmatrix}$
 $x = A x_1 + A x_2$

So we can write $e^{(1+2i)t} \begin{pmatrix} 0 \\ i \\ 1 \end{pmatrix}$ as $e^t \begin{pmatrix} 0 \\ \cos 2t + i \sin 2t \\ \cos 2t + i \sin 2t \end{pmatrix}$ that we are writing as $\begin{pmatrix} 0 \\ 1 \\ 1 \end{pmatrix}$. So here we are writing the real part different and imaginary part different. So now we multiply here. So first write down the real part that is $e^{2t} \begin{pmatrix} 0 \\ \cos 2t \\ \cos 2t \end{pmatrix}$ that this thing and when you multiply these 2 term will have negative part that is $\sin 2t \begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix}$. Similarly, we

can find out the complex part that is $e^{t} \cos 2t$ with 010 that is we are writing here and then this with this.

So $\sin 2t$ 001 , so $\sin 2t$ $001 e^{t}$ we are taking out. So we can write down the imaginary and real part in this way. If you add this, what you will get e^{t} and 0 and it is $-\sin 2t \cos 2t$ and here imaginary part is $i e^{t}$ and then it is $\cos 2t \sin 2t$. So here this is the real part and this is the imaginary part and we have already seen that real and imaginary also forms linearly independent set of solutions. This we have not proved.

We have just proved that if $x_t = y_t + iz_t$ is a complex solution, then y_t and z_t also is a solution of $\dot{x} = A(t)x(t)$. This we have proved, but we have not proved that y_t and z_t are linearly independent. In fact, we can prove in an easy manner. You simply just show that y_t and z_t are solutions corresponding to say different, distinct Eigenvectors corresponding to distinct Eigenvalues.

So this you try and we can prove that y_t in general that if $x_t = y_t + iz_t$ is a complex valued solution, then y_t and z_t are 2 real valued linearly independent solution of $\dot{x} = A(t)x(t)$ that you can verify. In fact, you can verify like this that $x_t = y_t + iz_t$, then you can find out the \bar{x}_t as $y_t - iz_t$. So we can write down y_t and z_t in terms of x_t and \bar{x}_t and then you can show that this x_t and \bar{x}_t are linearly independent. So y_t and z_t are also linearly independent.

(Refer Slide Time: 29:52)

Therefore

$$x^2(t) = e^t \begin{pmatrix} 0 \\ \cos 2t \\ \sin 2t \end{pmatrix} \quad \checkmark$$

and

$$x^3(t) = e^t \begin{pmatrix} 0 \\ \sin 2t \\ -\cos 2t \end{pmatrix} \quad \checkmark$$

You try, the characteristic of the matrix is that now we are able to find out 2 new linearly independent solution $x^2(t) = e^t \begin{pmatrix} 0 \\ \cos 2t \\ \sin 2t \end{pmatrix}$ and real part as $x^3(t) = e^t \begin{pmatrix} 0 \\ \sin 2t \\ -\cos 2t \end{pmatrix}$ that is this thing. So here we may observe this thing that $x^3(t)$ we have written as $e^t \begin{pmatrix} 0 \\ \sin 2t \\ -\cos 2t \end{pmatrix}$, but here it is just minus different, so it is $0 \begin{pmatrix} -\sin 2t \\ \cos 2t \end{pmatrix}$, but anyway if $x^3(t)$ is a solution, then $-x^3(t)$ is also a solution of $\dot{x} = A(t)x$, okay.

With this, we can say that x^2 and x^3 are 2 linearly independent solution of $\dot{x} = A(t)x$.

(Refer Slide Time: 30:38)

$$\text{Now } x^1(0) = \begin{pmatrix} 2 \\ -3 \\ 2 \end{pmatrix}, x^2(0) = \begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix} \text{ and } x^3(0) = \begin{pmatrix} 0 \\ 0 \\ -1 \end{pmatrix} \quad \checkmark \quad \checkmark \quad \checkmark$$

Therefore the solution $x(t)$ of our initial value problem must have the form

$$x(t) = c_1 e^t \begin{pmatrix} 2 \\ -3 \\ 2 \end{pmatrix} + c_2 e^t \begin{pmatrix} 0 \\ \cos 2t \\ \sin 2t \end{pmatrix} + c_3 e^t \begin{pmatrix} 0 \\ \sin 2t \\ -\cos 2t \end{pmatrix}.$$

So now we can write, we can check that $x^1(0)$ is $2 \begin{pmatrix} -3 \\ 2 \end{pmatrix}$, $x^2(0)$ is $0 \begin{pmatrix} 1 \\ 0 \end{pmatrix}$ and $x^3(0)$ is $0 \begin{pmatrix} 0 \\ -1 \end{pmatrix}$ and we can check easily that these 3 are linearly independent Eigenvectors of $A(0)$. So it means if these 3 are

linearly independent Eigenvectors of r_3 and $x_1, x_2,$ and x_3 are 3 solutions of $\dot{x} = A(t)x$, then it will form 3 linearly independent solutions of $\dot{x} = A(t)x$ and we can write down the general solution of our initial value problem as this $x(t) = c_1 e^{2t} - 3c_2 e^{0t} \cos 2t \sin 2t + c_3 e^{0t} \sin 2t - \cos 2t$.

So general solution of homogeneous problem is written like this. Now with the help of this, we can form the fundamental matrix of solution.

(Refer Slide Time: 31:36)

A fundamental matrix solution of $\dot{x} = Ax$ may be given as

$$X(t) = \begin{pmatrix} 2e^t & 0 & 0 \\ -3e^t & e^t \cos 2t & e^t \sin 2t \\ 2e^t & e^t \sin 2t & -e^t \cos 2t \end{pmatrix}$$

$\chi^1 \quad \chi^2 \quad \chi^3$

χ

That is this is your $x_1(t)$, this x_2 , it is x_3 . So we can write down the fundamental matrix of $\dot{x} = Ax$ may be given as $x(t) = 2e^t - 3e^t \cos 2t \sin 2t + e^t \sin 2t - e^t \cos 2t$ and once your $x(t)$ is given to us and we have already checked that it is, these 3 solutions are linearly independent solution. So $x(t)$ is an invertible matrix, that is non-singular matrix.

(Refer Slide Time: 32:11)

Observe that $X(0) = \begin{pmatrix} 2 & 0 & 0 \\ -3 & 1 & 0 \\ 2 & 0 & -1 \end{pmatrix}$ and $\det(X(0)) = -2 \neq 0$, therefore X is an invertible matrix and its inverse matrix X^{-1} is given by

$$X^{-1}(0) = \begin{pmatrix} \frac{1}{2} & 0 & 0 \\ \frac{3}{2} & 1 & 0 \\ 1 & 0 & -1 \end{pmatrix}.$$

Hence, we can calculate the fundamental matrix solution e^{At} as follows:

$$\begin{aligned} e^{At} &= X(t)X(0)^{-1} \\ &= e^t \begin{pmatrix} 1 & 0 & 0 \\ \frac{-3}{2} + \frac{3}{2}\cos 2t + \sin 2t & \cos 2t & -\sin 2t \\ 1 + \frac{3}{2}\sin 2t - \cos 2t & \sin 2t & \cos 2t \end{pmatrix}. \end{aligned}$$

So we can observe the value of $X(0)$, which is coming as 2 -3 2 0 1 0 0 -1 and we can check that determinant of $X(0)$ is coming out to be non-zero and hence we can find out the inverse of $X(0)$ that is $1/2$ 0 0 $3/2$ 1 0 1 0 -1. You can find out the inverse using your properties of matrix and you can easily find out the inverse of $X(0)$ and it is given as X inverse(0). So idea is to calculate e to power $A(t)$, the fundamental matrix solution e to power $A(t)$ is now calculated as $x(t)x_0$ inverse.

We are writing e to power t $x(t)$ is already given to us, X inverse(0) we have just calculated. So we multiply $x(t)$ and $X(0)$ inverse and we have the following solution, following matrix as a fundamental matrix solution e to power $A(t)$.

(Refer Slide Time: 33:11)

Consequently

$$x(t) = e^{A(t-t_0)} + \int_{t_0}^t e^{A(t-s)} f(s) ds.$$

$$x(t) = e^{At} \begin{pmatrix} 0 \\ 1 \\ 1 \end{pmatrix} + e^{At} \int_0^t e^{-s} ds \quad (6)$$

$$\times \begin{pmatrix} 1 & 0 & 0 \\ -\frac{3}{2} + \frac{3}{2} \cos 2s + \sin 2s & \cos 2s & -\sin 2s \\ 1 + \frac{3}{2} \sin 2s - \cos 2s & \sin 2s & \cos 2s \end{pmatrix} \times \begin{pmatrix} 0 \\ 0 \\ e^t \cos 2s \end{pmatrix} ds \quad (7)$$

Hence we get

$$x(t) = e^t \begin{pmatrix} 0 \\ \cos 2t - (1 + \frac{1}{2}) \sin 2t \\ (1 + \frac{1}{2}) \cos 2t + \frac{5}{4} \sin 2t \end{pmatrix}.$$

So now e^{At} is given to us, then we can use our formula to find out the solution of non-homogeneous problem that is $x(t) = e^{A(t-t_0)} + \int_{t_0}^t e^{A(t-s)} f(s) ds$. So here e^{At} is already known to us. t_0 is coming out to be 0, so we can write $e^{A(t-t_0)}$ as e^{At} . This is $x(t_0)$. So $x(t_0)$ is $\begin{pmatrix} 0 \\ 1 \\ 1 \end{pmatrix}$. Now we are writing $e^{-A(s)}$ as e^{-s} as e^{At} is given here, then $e^{-A(s)}$ is simply replace t by $-s$ and we can write down $e^{-A(s)}$ and we can write it like this.

So here you can check that it is actually written as e^{-As} and we can have this. And multiply by $f(s)$ that is $\begin{pmatrix} 0 \\ 0 \\ e^t \cos 2s f(s) \end{pmatrix}$ we are writing here. We can multiply this expression into e^{-s} , you can integrate with respect to 0 to t and then multiply e^{At} and we simplify and we can have this as a solution $x(t) = e^t \begin{pmatrix} 0 \\ \cos 2t - (1 + \frac{1}{2}) \sin 2t \\ (1 + \frac{1}{2}) \cos 2t + \frac{5}{4} \sin 2t \end{pmatrix}$ and this process is quite lengthy and tiring, so we can see that even though we are able to find out e^{At} , but this calculation is quite lengthy, I will say.

So finding the solution of non-homogeneous problem using variation of parameter method is quite difficult. So another alternative method available to find out the solution of non-homogeneous linear system is the use of nice guess. So if you look at $f(t)$ is $\begin{pmatrix} 0 \\ 0 \\ e^t \cos 2t \end{pmatrix}$, so it means that here you can say that this we can find out the possible way of solution is something like $\alpha e^t \cos 2t + \beta e^t \sin 2t$.

And then we try in to find out alpha beta in a suitable manner such that it will satisfy this non-homogeneous problem. This is something, which you do for the scalar valued function. So you can see that both are giving you the same result, that is given here as this. Now let us consider one more example, so that this can be simplified in a better way.

(Refer Slide Time: 36:07)

Example 2

Solve the following initial value problem

$$\dot{x} = \begin{pmatrix} 1 & 0 \\ 0 & 2 \end{pmatrix} x + \begin{pmatrix} \sin at \\ \cos bt \end{pmatrix}, \quad x(0) = \begin{pmatrix} 0 \\ 1 \end{pmatrix}.$$

Solution Let λ be an eigenvalue of the matrix $A = \begin{pmatrix} 1 & 0 \\ 0 & 2 \end{pmatrix}$. Then the characteristic polynomial of A is given by

$$|A - \lambda I| = \begin{vmatrix} 1 - \lambda & 0 \\ 0 & 2 - \lambda \end{vmatrix}$$

Hence the characteristic equation of A is given by

$$(1 - \lambda)(2 - \lambda) = 0$$

i.e. $\lambda_1 = 1$ and $\lambda_2 = 2$.

So let us consider 2x2 matrix case, where this can be further simplified. So solve the following initial value problem $\dot{x} = \begin{pmatrix} 1 & 0 \\ 0 & 2 \end{pmatrix} x + \begin{pmatrix} \sin at \\ \cos bt \end{pmatrix}$, initial condition is given as $x(0) = \begin{pmatrix} 0 \\ 1 \end{pmatrix}$ here. So forcing to find out e to power At at fundamental matrix solution of $\dot{x} = Ax$ where A is given as $\begin{pmatrix} 1 & 0 \\ 0 & 2 \end{pmatrix}$. So we have taken very simple case. If you look at this, nothing but diagonalizable case. So we can find out the Eigenvalues in a very easy manner.

That is nothing but the diagonal entry of this matrix. So $\lambda_1 = 1$ and $\lambda_2 = 2$ Eigenvalue of matrix A .

(Refer Slide Time: 36:47)

Eigenvector corresponding to $\lambda_1 = 1$:

$$\begin{pmatrix} 1-1 & 0 \\ 0 & 2-1 \end{pmatrix} \begin{pmatrix} x_1 \\ y_1 \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \end{pmatrix}.$$

On simplification, we have an eigenvector $v_1 = \begin{pmatrix} x_1 \\ y_1 \end{pmatrix} = \begin{pmatrix} 1 \\ 0 \end{pmatrix}$. $x_1(t) = e^t \begin{pmatrix} 1 \\ 0 \end{pmatrix}$

Eigenvector corresponding to $\lambda_2 = 2$:

$$\begin{pmatrix} 1-2 & 0 \\ 0 & 2-2 \end{pmatrix} \begin{pmatrix} x_2 \\ y_2 \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \end{pmatrix}.$$

On simplification we have $\begin{pmatrix} x_2 \\ y_2 \end{pmatrix} = \begin{pmatrix} 0 \\ 1 \end{pmatrix}$. $x_2(t) = e^{2t} \begin{pmatrix} 0 \\ 1 \end{pmatrix}$

So we can find out the Eigenvector corresponding to lambda 1=1 that is coming out to be 1 0, so we can simply write it here that y1 is coming out to be 0. So x1 you can take arbitrary value. In particular, I am taking value as 1. So Eigenvector corresponding to lambda 1=1 is 1 0. So we can write down the first solution $x_1(t) = e^t \begin{pmatrix} 1 \\ 0 \end{pmatrix}$. Similarly, we can find out the Eigenvector corresponding to lambda 2=2 and you can see that your x2 is coming out to be 0 here.

So y2 is, you can take any arbitrary value, we have taken the particular value that is 1. So Eigenvector corresponding to lambda 2=2 is given as 0 1. So your $x_2(t)$ is given as $e^{2t} \begin{pmatrix} 0 \\ 1 \end{pmatrix}$ and 0 and 1. So $x_1(t)$ and $x_2(t)$ are coming out to be very easily.

(Refer Slide Time: 37:40)

Then a fundamental matrix solution of $\dot{x} = Ax$ may be given as

$$X(t) = \begin{pmatrix} e^t & 0 \\ 0 & e^{2t} \end{pmatrix}. \quad X(0) = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$$

Since $X(t)$ is a nonsingular matrix, we can calculate its inverse as:

$$X^{-1}(0) = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$$

Therefore, the fundamental matrix solution e^{At} is given by

$$e^{At} = \begin{pmatrix} e^t & 0 \\ 0 & e^{2t} \end{pmatrix} \quad e^{-At} = \begin{pmatrix} e^{-t} & 0 \\ 0 & e^{-2t} \end{pmatrix}$$

And we can write down the fundamental matrix solution as $x_1(t)$, $x_1(t)$ is e^{at} and $x_2(t)$ is $0 e^{2t}$, right. So that we have written here. So this we can write e^{at} and this we can write it $0 e^{2t}$. So with the help of $x_1(t)$ $x_2(t)$ we have written $x(t)$ as e^{at} $0 e^{2t}$ and we can write down $x(0)$ is nothing but $1 \ 0 \ 0 \ 1$. So it is an identity matrix, so it is invertible. So $x(t)$ is a fundamental matrix solution.

So we can find out the inverse of this and since it is identity matrix inverse is coming out to be identity equal. So e^{at} is nothing but the $x(t) \cdot x^{-1}(t)$, so that is coming out to be $x(t)$ itself. So e^{at} is coming out to be e^{at} $0 e^{2t}$. So now we can find out the inverse of this.

(Refer Slide Time: 38:34)

Consequently

$$\begin{aligned}
 x(t) &= e^{At} \begin{pmatrix} 0 \\ 1 \end{pmatrix} \\
 &+ e^{At} \int_0^t \begin{pmatrix} e^{-s} & 0 \\ 0 & e^{-2s} \end{pmatrix} \begin{pmatrix} \sin as \\ \cos bs \end{pmatrix} ds \\
 &= e^{At} \begin{pmatrix} 0 \\ 1 \end{pmatrix} \\
 &+ e^{At} \int_0^t \begin{pmatrix} \frac{e^{-s} \sin as}{e^{-2s} \cos bs} \end{pmatrix} ds = e^{At} \begin{pmatrix} 0 \\ 1 \end{pmatrix} + e^{At} \int_0^t \begin{pmatrix} \frac{e^{-s} \sin as}{(1+a^2)} [-\sin as - a \cos as] \\ \frac{e^{-2s}}{(4+b^2)} [-2 \cos bs + b \sin bs] \end{pmatrix} ds
 \end{aligned}$$

And inverse of this is nothing but so e^{-As} as you can write simply as e^{-s} $0 e^{-2s}$, right. Now we can write down the formula here. Formula is this, $x(t) e^{-As}$, initial condition $x(0)$ is $0 \ 1 + e^{at}$ $0 \ 1 \ 0 \ t e^{-s}$ $0 e^{-2s} \sin as \sin bs \ ds$. This is as it is. Now e^{at} we have taken out $0 \ t$, if you multiply what you will get, it is nothing but $e^{-s} \sin as$ and this is nothing but $e^{-2s} \cos bs \ ds$.

So we can integrate this is nothing but e^{at} $0 \ 1 + e^{at}$ and $0 \ t$ and now rather than we can take integration of this matrix is nothing but integration of each component. Now you can find out the integration of $e^{-s} \sin as$ and $e^{-2s} \cos bs$ and it is coming

out to be this that e to power $-s/1+a^2-\sin as-a \cos as$. Similarly, we can find out 0 to t e to power $-2s \cos bs$ as e to power $-2s 4+b^2-2 \cos bs+b \sin 2s 0t$. So now we just plug in the limits here and we can plug in the limits.

(Refer Slide Time: 40:01)

$$\begin{aligned}
 &= \begin{pmatrix} 0 \\ e^{2t} \end{pmatrix} + \begin{pmatrix} e^t & 0 \\ 0 & e^{2t} \end{pmatrix} \\
 &\quad \left(\begin{array}{l} \frac{e^{-t}}{(1+a^2)}[-\sin at - a \cos at] + \frac{a}{1+a^2} \\ \frac{e^{-2t}}{(4+b^2)}[-2 \cos bt + b \sin bt] + \frac{2}{4+b^2} \end{array} \right) \\
 &= \begin{pmatrix} 0 \\ e^{2t} \end{pmatrix} + \\
 &\quad \left(\begin{array}{l} \frac{1}{(1+a^2)}[-\sin at - a \cos at] + \frac{ae^t}{1+a^2} \\ \frac{1}{(4+b^2)}[-2 \cos bt + b \sin bt] + \frac{2e^{2t}}{4+b^2} \end{array} \right) \\
 &= \left(\begin{array}{l} \frac{1}{(1+a^2)}[ae^t - (\sin at + a \cos at)] \\ \frac{1}{(4+b^2)}[(6 + b^2)e^{2t} + (-2 \cos bt + b \sin bt)] \end{array} \right) \checkmark
 \end{aligned}$$

And we can have like 0 e to t that we have just calculated e to power $At*0 1$ that is coming out to be $0A2t$ +this is e to power $At*$ this, this we have plug in the value. So here when we multiply and we have the following value e to power $-t 1+a^2-\sin at -a \cos 2at$ +this thing and in this we have plug in the limits of $0t$ and when you simplify you have this solution. This is quite lengthy, I will say, though it is 2×2 case, but still it is quite lengthy.

We say that though it is a very good method and you can find out the solution of almost all the problems, but it is quite lengthy. So I suggest that you can also consider the solution system which involves the guessing, say finding the undetermined coefficient method of undetermined coefficient you can try finding the solution of non-homogeneous linear system. So with this I end this lecture.

We will continue our study in next lecture. So in this lecture, we have discussed the solution of non-homogeneous linear differential equation with the help of solution of homogeneous linear differential equation and we have used the method of variation of parameter method in this lecture and also observed that though this process is quite lengthy, but it is quite reliable and you

can find out the solution of almost all the linear non-homogeneous problems with the help of the present method, which we have just presented.

Other alternative methods available are method of undetermined coefficients and other method. So with this we end our lecture. Thank you very much for listening this. Thank you.
