Lecture - 19
Stability of Weakly Non Linear Systems - II

Hello friends. Welcome to this lecture. In this lecture, we will continue our study of stability of nonlinear system. So if you recall in previous class, we are discussing the following system of differential equation that is $\dot{x} = Ax + g(x)$ where x is $n \times 1$ vector and A is $n \times n$ matrix and g is the $n \times 1$ matrix function.

(Refer Slide Time: 00:53)

Stability of equilibrium solutions

Consider the differential equation

$$\dot{x} = \underline{Ax} + \underline{g(x)} \quad (1)$$

where the nonlinear part

$$\underline{g(x)} = \begin{pmatrix} g_1(x) \\ \vdots \\ g_n(x) \end{pmatrix}$$

is small when x is small and

$$\frac{g_i(x)}{\|x\|}, \quad i = 1, \dots, n$$

are continuous functions of x_1, \dots, x_n and vanishes for $x_1 = \dots = x_n = 0$.

g(x) = 0 for x = 0

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 2

It is given as $g(x) = [g_1(x) \dots g_n(x)]^T$ and here we are assuming that the nonlinearity given by the function g of x say is small compared to the linear part that is A of x . So here we have assumed that $g(x)$ is a function such that $g(x)/\|x\|$ is $O(\|x\|)$ (01:20) $g_i(x)/\|x\|$ are continuous function of x_1 to x_n and vanishes for x_1 to $x_n = 0$. So here by putting this condition that $g(0) = 0$ for $x = 0$ simply says that $x = 0$ is an equilibrium solution of the system 1.

(Refer Slide Time: 01:44)

If $g(0) = 0$ then $x(t) \equiv 0$ is an equilibrium solution of (1). Such a system is called a weakly nonlinear system.

In the case of nonlinear systems stability of every solution may not be determined but in some cases with the help of stability of zero solution of its linearized problem, we may discuss the stability of its equilibrium solutions. In this regard, the following theorem is quite useful:

Theorem 1

Suppose that the vector-valued function

$$g(x)/\|x\| \quad \checkmark$$

is a continuous function of x_1, \dots, x_n which vanishes for $x = 0$.

And here and we call this kind of a system as weakly nonlinear system and we have discussed, we have started proving the theorem number 1 which says that suppose the vector-valued function $g(x)/\|x\|$ is a continuous function of x_1 to x_n which vanishes for $x=0$.

(Refer Slide Time: 02:06)

Then,

- The equilibrium solution $x(t) \equiv 0$ of (1) is asymptotically stable if the equilibrium solution $x(t) \equiv 0$ of the "linearized" equation $\frac{dx}{dt} = Ax$ is asymptotically stable. Equivalently, the solution $x(t) \equiv 0$ of (1) is asymptotically stable if all the eigenvalues of A have negative real part.
- The equilibrium solution $x(t) \equiv 0$ of (1) is unstable if at least one eigenvalue of A have positive real part.
- The stability of the equilibrium solution $x(t) \equiv 0$ of (1) can not be determined from the stability of the equilibrium solution $x(t) \equiv 0$ of $\frac{dx}{dt} = Ax$ if all the eigenvalues of A have real part ≤ 0 but at least one eigenvalue of A has zero real part.

Then, the part a that the equilibrium solution $x(t) \equiv 0$ of (1) is asymptotically stable if the equilibrium solution of $x(t) \equiv 0$ of the linearized equation that is $\frac{dx}{dt} = Ax$ is asymptotically stable and we have already seen that the system of linear equation $\frac{dx}{dt} = Ax$ every solution of this will be asymptotically stable provided that all the eigenvalues of A have negative real part.

So it means we can say that we summarize these two facts then we can say that the equilibrium solution $x(t) \equiv 0$ of (1) is asymptotically stable if all the eigenvalues of A

have negative real part. So and the part b says that the equilibrium solution $x(t) \equiv 0$ of (1) is unstable if at least one eigenvalue of A has positive real part, so this is the b part.

And c part is that the stability of the equilibrium solution $x(t) \equiv 0$ of (1) cannot be determined from the stability of the equilibrium solution $x(t) \equiv 0$ of dx/dt if all the eigenvalues of A have real part ≤ 0 but at least one eigenvalue of A has zero real part and in last lecture we have discussed say two examples based on the part c.

(Refer Slide Time: 03:41)

and the eigenvalues of the matrix

$$\begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}$$

are $\pm i$ and falls under the case given in (c).

To discuss the behavior of the nonlinear system (2), we multiply the first equation by x_1 , the second equation by x_2 and add; which gives

$$\begin{aligned} x_1 \frac{dx_1}{dt} + x_2 \frac{dx_2}{dt} &= -x_1^2(x_1^2 + x_2^2) - x_2^2(x_1^2 + x_2^2) \\ &= -(x_1^2 + x_2^2)^2. \end{aligned}$$

Hence,

$$\frac{d}{dt}(x_1^2 + x_2^2) = -2(x_1^2 + x_2^2)^2.$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 6

In fact, we started with part c and we have shown that in this part when $dx_1/dt = x_2 - x_1^2 - x_2^2$, $dx_2/dt = -x_1 - x_2^2$. In this case, your coefficient matrix of the linearized system has zero real part.

(Refer Slide Time: 04:04)

This implies that

$$x_1^2(t) + x_2^2(t) = \frac{c}{1 + 2ct},$$

where

$$c = x_1^2(0) + x_2^2(0).$$

Hence $x_1^2(t) + x_2^2(t) \rightarrow 0$ as $t \rightarrow \infty$ for any solution $x_1(t), x_2(t)$ of (2).

Also, we may observe that the value of $x_1^2 + x_2^2$ at any time t is always less than its value at $t = 0$.

Hence the trivial solution $x_1(t) \equiv 0, x_2(t) \equiv 0$ is asymptotically stable.

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 7

And here we have seen that the solution is asymptotically stable.

(Refer Slide Time: 04:09)

On the other hand, consider now the following system of differential equations

$$\frac{dx_1}{dt} = x_2 + x_1(x_1^2 + x_2^2), \quad \frac{dx_2}{dt} = -x_1 - x_2(x_1^2 + x_2^2). \quad (3)$$

Then the associated linear system is given by

$$\frac{dx}{dt} = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix} x.$$

But now, $\frac{d}{dt}(x_1^2 + x_2^2) = 2(x_1^2 + x_2^2)^2$, which implies that

$$x_1^2(t) + x_2^2(t) = \frac{c}{1 - 2ct}, \quad c = x_1^2(0) + x_2^2(0).$$

We may observe that every solution $x_1(t), x_2(t)$ of (3) with $x_1^2(0) + x_2^2(0) \neq 0$ approaches infinity in finite time. Hence, the equilibrium solution $x_1(t) \equiv 0, x_2(t) \equiv 0$ is an unstable solution.

Handwritten notes:
 $\frac{dx}{dt} = (Ax + g(x))$
 $\frac{d(x^2)}{dt} = 2(x^2)$

But if we just perturb our system of differential equation like this that $dx_1/dt = x_2 + x_1(x_1^2 + x_2^2)$ and $dx_2/dt = -x_1 - x_2(x_1^2 + x_2^2)$. If you look carefully, then the associated linear system is same and the eigenvalues of A is having zero real part and in previous question we have shown that the zero solution is asymptotically stable solution but in this case your zero solution, the equilibrium solution $x_1(t) \equiv 0$ and $x_2(t) \equiv 0$ is an unstable solution.

So it means that if you are discussing $dx/dt = Ax + g(x)$ of x where x satisfying the condition that $g(0) = 0$ and $g(x)/\|x\|$ is a continuous function of x and it vanishes as $x \rightarrow 0$. Then, we cannot conclude anything if eigenvalues of A, all the eigenvalues of A are nonpositive and at least one of the eigenvalues has zero real part. So in that case, we cannot conclude anything. Now let us prove the result for the first two cases.

That is that eigenvalues of A are having negative real part for all the eigenvalues and if at least one of the eigenvalues have positive real part. So let us prove in the case of 1 and 2.

(Refer Slide Time: 05:50)

Proof

$$\begin{aligned} \dot{x} &= Ax + g(x) \\ \dot{x} &= Ax \\ x(t) &= X(t)C \quad \checkmark \end{aligned}$$

We may observe that any solution $x(t)$ of (1) may be written in the form

$$x(t) = e^{At}x(0) + \int_0^t e^{A(t-s)}g(x(s))ds. \quad \checkmark \quad (4)$$

Since we are looking for the asymptotic stability of zero solution, we want to show that $\|x(t)\| \rightarrow 0$ as $t \rightarrow \infty$.

So we may observe that any solution $x(t)$ of (1), here (1) is $\dot{x} = Ax + g(x)$, here we can say that this any solution of this may be written in the following form that $x(t) = e^{At}x(0) + \int_0^t e^{A(t-s)}g(x(s))ds$ and here we have used the variation of parameter method. In fact, we know that we can write down the solution of $\dot{x} = Ax$ as say this is the fundamental matrix $X(t) * \text{that constant function } c$.

So your $x(t)$ homogenous part can be written as $X(t) * c$ and then by varying the c we can find out the solution of this and this is I think we have already discussed in one of the lecture. So we can say that here taking this fundamental matrix solution $X(t)$ as e^{At} we can write down the solution of $\dot{x} = Ax + g(x)$ as follows that is it is $x(t) = e^{At}x(0) + \int_0^t e^{A(t-s)}g(x(s))ds$.

And here since we are looking for the asymptotic stability of zero solution, it means that we are looking at that this zero solution is a stable solution and any other solution which start in the neighborhood of zero solution will tend to zero as t tending to infinity. So this we can prove provided that norm of $x(t)$ is tending to 0 as t tending to infinity can be proved. So our focus is to prove that norm of $x(t)$ is tending to 0 as t tending to infinity okay.

(Refer Slide Time: 07:40)

As observed earlier we know that if all the eigenvalues of A have negative real part, then we can find positive constants K and α such that

$$\|e^{At}x(0)\| \leq Ke^{-\alpha t}\|x(0)\|, \quad \checkmark \quad \|e^{At}\| \leq Ke^{-\alpha t}$$

and

$$\|e^{A(t-s)}g(x(s))\| \leq Ke^{-\alpha(t-s)}\|g(x(s))\|.$$

Now as we have observed in the case that if all the eigenvalues of A have negative real part, then we can find out a constant k and α in a way such that this e to power norm of e to power At is bounded by Ke to power $-\alpha t$, so that we have already discussed in previous few lectures. Now here using this let us find out the upper bound of norm of e to power $At * x$ of 0 which is nothing but \leq norm of e to power $At * \text{norm of } x_0$.

Norm of e to power At is bounded by Ke to power $-\alpha t$. So we can say that norm of e to power $At * x_0$ is $\leq Ke$ to power $-\alpha t$ norm of x_0 . Now once we have this now let us look at because here if we have two terms, one term is here, another term is inside. So this can be bounded by Ke to power $-\alpha t$ norm of x_0 . Now look at the integrant basically e to power $A t-s$ of $x s$.

Here in a similar way we can say that norm of e to power $A t-s$ of $x s$ is $\leq Ke$ to power $-\alpha t-s$ norm of g of $x s$. So here we have shown we have found the upper bound here. Now still it is not sufficient because it is quite difficult to say simplify this expression 4.

(Refer Slide Time: 09:20)

Also, we can find a positive constant β such that

$$\|g(x)\| \leq \frac{\alpha}{2K} \|x\|, \text{ if } \|x\| \leq \beta. \quad \checkmark$$

This follows from the fact that the function $\frac{g(x)}{\|x\|}$ is continuous and vanishes at $x = 0$.

$\forall \epsilon > 0 \exists \delta > 0$ s.t. $\left\| \frac{g(x)}{\|x\|} - 0 \right\| < \epsilon$ whenever $\|x\| < \delta$

$\checkmark \left\| \frac{g(x)}{\|x\|} \right\| < \epsilon \Rightarrow \epsilon = \frac{\alpha}{2K}$

So here we also use the following thing that we can find a positive constant beta such that norm of gx is \leq some constant * norm of x and if norm of x is $<$ beta and this follows from the fact that this $gx/\text{norm of } x$ is continuous and vanishes at $x=0$. So how we can obtain this if you look at the continuity of $gx/\text{norm of } x$. So we can simply say that norm of g of x/norm of x $\rightarrow 0$ because it is vanishing at 0 is $<$ epsilon whenever, so continuity says that for every epsilon $>$ 0 there exists a delta $>$ 0.

Such that this quantity is $<$ epsilon whenever norm of x is $<$ delta and this is what this I can write it $gx/\text{norm of } x$ is $<$ epsilon. So now for this particular problem let us choose epsilon as $\alpha/2k$. We will see that why this $\alpha/2k$ I have taken. You can take any constant, later on we can fix that. Now this delta let us say call it beta here.

So we say that since $gx/\text{norm of } x$ is a continuous function and continuous function for norm of x and continuous function of x and it is tending to 0 as x is tending to 0. So with the help of this, we can say that norm of gx is $\leq \alpha/2k * \text{norm of } x$ provided that norm of x is \leq beta here. So corresponding to $\alpha/2k$ we can find out delta and let us call that delta as beta.

So it means that using continuity, we can write that norm of gx is $\leq \alpha/2k * \text{norm of } x$ if norm of x is \leq some beta. Now that beta is depending on this $\alpha/2k$ here.

(Refer Slide Time: 11:32)

Therefore, from equation (1), we have

$$\|x(t)\| \leq \|e^{At}x(0)\| + \int_0^t \|e^{A(t-s)}g(x(s))\| ds$$

$$\leq Ke^{-\alpha t}\|x(0)\| + \frac{\alpha}{2} \int_0^t e^{-\alpha(t-s)}\|x(s)\| ds$$

whenever $\|x(s)\| \leq \beta$, $0 \leq s \leq t$. Further simplifying, we get

$$e^{\alpha t}\|x(t)\| \leq K\|x(0)\| + \frac{\alpha}{2} \int_0^t e^{\alpha s}\|x(s)\| ds.$$

$$\|e^{A(t-s)}\| \leq Ke^{-\alpha(t-s)}$$

$$\|g(x(s))\| \leq \frac{\alpha}{2}K\|x(s)\|$$

Now once you have all these things then we can look at our solution that is norm of $x(t) \leq \|e^{At}x(0)\| + \int_0^t \|e^{A(t-s)}g(x(s))\| ds$. Now this quantity is $\leq Ke^{-\alpha t}\|x(0)\| + \int_0^t Ke^{-\alpha(t-s)}\|g(x(s))\| ds$. Now this is $\leq Ke^{-\alpha t}\|x(0)\| + \int_0^t Ke^{-\alpha(t-s)}\frac{\alpha}{2}K\|x(s)\| ds$. Now this norm of g of x of s is $\leq \frac{\alpha}{2}K\|x(s)\|$. Now that one K like here it is $e^{-\alpha(t-s)}$ is bounded by $Ke^{-\alpha(t-s)}$ and norm of g of x of s is bounded by $\frac{\alpha}{2}K\|x(s)\|$.

So this K will be canceled out here and you will get $\frac{\alpha}{2} \int_0^t e^{-\alpha(t-s)}\|x(s)\| ds$. Now here this inequality will be true provided that norm of x is $\leq \beta$ where s is lying between 0 to t here because s is lying between 0 to t here. So if you further simplify in fact we can multiply on both the side by $e^{\alpha t}$ and then we can have $e^{\alpha t}\|x(t)\| \leq K\|x(0)\| + \frac{\alpha}{2} \int_0^t e^{\alpha s}\|x(s)\| ds$ here.

(Refer Slide Time: 13:10)

This inequality can be simplified by setting $z(t) = e^{\alpha t} \|x(t)\|$, for then

$$z(t) \leq K \|x(0)\| + \frac{\alpha}{2} \int_0^t z(s) ds.$$

We see that

$$\|x(t)\| = e^{-\alpha t} \|z(t)\| \leq K \|x(0)\| e^{-\frac{\alpha t}{2}}$$

as long as $\|x(s)\| \leq \beta, 0 \leq s \leq t$.

Handwritten notes and derivations:

- $z'(t) \leq K \|x(0)\| + \alpha z(t)$
- $z'(t) \leq e^{\frac{\alpha t}{2}} K \|x(0)\|$
- $U(t) = \int_0^t z(s) ds$
- $U'(t) = z(t)$
- $U'(t) \leq \frac{\alpha}{2} K \|x(0)\| e^{\frac{\alpha t}{2}}$
- $\|x(t)\| \leq K \|x(0)\| e^{-\frac{\alpha t}{2}}$
- $\|x(s)\| \leq \beta, 0 \leq s \leq t$
- $\Rightarrow U'(t) - \frac{\alpha}{2} U(t) \leq \frac{\alpha}{2} K \|x(0)\| e^{-\frac{\alpha t}{2}}$
- $\frac{d}{dt} \left(e^{-\frac{\alpha t}{2}} U(t) \right) \leq \frac{\alpha}{2} K \|x(0)\| e^{-\frac{\alpha t}{2}}$

So this we can further simplify by taking $z(t) = e^{\alpha t} \|x(t)\|$ and then we can write it $z(t) \leq K \|x(0)\| + \frac{\alpha}{2} \int_0^t z(s) ds$ here. So here we want to find out the bound on $z(t)$ here. So here we have two ways, either you use directly the Gronwall's inequality if you know, otherwise we can solve this by taking let us say $u(t) = \int_0^t z(s) ds$ here.

So the only thing is that we cannot solve for $z(t)$ by just differentiating it because differentiation of the inequality may not be preserved here. So to solve this, we let us assume that $u(t) = \int_0^t z(s) ds$. Then, we can write down $u'(t) = z(t)$ here and it is $z(t)$ here. So we can say that we already know that $z(t) \leq$ this quantity, so we can write $u'(t) = z(t) \leq$ this quantity, so it is $K \|x(0)\| + \frac{\alpha}{2} u(t)$.

Now this quantity is what, this quantity is your $u(t)$, so let me write it here. So this is what $u'(t) = z(t) \leq K \|x(0)\| + \frac{\alpha}{2} u(t)$ here. So what we have done here, we just assumed this quantity as $u(t)$ and then we have evaluated the derivative of this that this $u'(t) = z(t) \leq K \|x(0)\| + \frac{\alpha}{2} u(t)$. Now $z(t)$ we know that the upper bound of $z(t)$ is what, $z(t)$ is bounded by $K \|x(0)\| + \frac{\alpha}{2} u(t)$ here.

So now using the bound of $z(t)$ I can write down $u'(t) \leq K \|x(0)\| + \frac{\alpha}{2} u(t)$. So we can write down $u'(t) - \frac{\alpha}{2} u(t) \leq K \|x(0)\|$. Now here this we can solve in terms of $u(t)$ here. For that we simply multiply by $e^{-\frac{\alpha t}{2}}$ here. If you multiply here, then I can write this as $\frac{d}{dt}$ of this is what let us say $-$ sign here, then this will give you what $e^{-\frac{\alpha t}{2}} u(t)$.

If you differentiate this what you will get, this u and differentiation of this will be what, e to power $-\alpha/2$ and if you take this as e to power $-\alpha t$ and u now this is $\leq \alpha/2 K$ times norm of x_0 e to power $-\alpha t/2$. So what we have done we multiplied by e to power $-\alpha t/2$ then this left hand side is reduced to d/dt of e to power $-\alpha t/2$ and right hand side we have written $\alpha/2 K$ times norm of x_0 e to power $-\alpha t/2$ here.

Now let us so we are solving this d/dt of e to power $-\alpha t/2$ u of t which is $\leq \alpha/2 K$ times norm of x_0 e to power $-\alpha t/2$ and this we can solve as follows.

(Refer Slide Time: 17:12)

The slide shows the following handwritten derivation:

$$\frac{d}{dt} \left(e^{-\frac{\alpha t}{2}} U(t) \right) \leq e^{-\frac{\alpha t}{2}} \frac{\alpha K}{2} \|x(0)\|$$

$$\Rightarrow \frac{d}{dt} \left(e^{-\frac{\alpha t}{2}} U(t) \right) - \frac{\alpha}{2} e^{-\frac{\alpha t}{2}} K \|x(0)\| \leq 0 \quad \checkmark$$

$$\Rightarrow \frac{d}{dt} \left(e^{-\frac{\alpha t}{2}} U(t) \right) + \frac{d}{dt} \left(e^{-\frac{\alpha t}{2}} K \|x(0)\| \right) \leq 0 \quad \checkmark \quad U(0) = \int_0^t z(s) ds$$

$$\Rightarrow \frac{d}{dt} \left(e^{-\frac{\alpha t}{2}} \left(U(t) + K \|x(0)\| \right) \right) \leq 0 \quad \checkmark \quad U(0) = 0$$

$$\Rightarrow e^{-\frac{\alpha t}{2}} \left(U(t) + K \|x(0)\| \right) \leq \frac{U(0) + K \|x(0)\|}{1}$$

$$\textcircled{z(t)} \leq U(t) + K \|x(0)\| \leq e^{\frac{\alpha t}{2}} K \|x(0)\|$$

We can write down d/dt of e to power $-\alpha t/2$ u of $t \leq e$ to power $-\alpha t/2$ $\alpha/2 K$ times norm of x_0 here. Now this we can take it in left hand side and we can write d/dt e to power $-\alpha t/2$ u $-\alpha/2 e$ to power $-\alpha t/2$ K times norm of x_0 is ≤ 0 here. Now this part I can write as d/dt of e to power $-\alpha t/2$ K times norm of x_0 . So using this we can write down this as d/dt e to power $-\alpha t/2$ $u + K$ times norm of $x_0 \leq 0$ here.

Now we simply integrate with respect to t from 0 to t , so we have e to power $-\alpha t/2$ $u + K$ times norm of $x_0 \leq$ putting the value 0 here. Then, e to power $-\alpha 0/2$ is simply 1 that is $u_0 + K$ times norm of x_0 . Now what is u_0 here, so u_0 you can simply find out using this that $u = \int_0^t z(s) ds$. Now if you put $t=0$ here, then this integral will vanish, this whole thing will vanish and you can get the value of $u_0=0$ here.

So we can get that $e^{-\alpha t/2}$ times K times norm of x_0 is given by this is simply K times norm of x_0 . So here we can get the value of t that $e^{-\alpha t/2}$ times norm of x_0 is $\leq e^{-\alpha t/2} K$ times norm of x_0 and if you look at this is the bound of $z(t)$. So $z(t)$ is bounded by $e^{-\alpha t/2} K$ times norm of x_0 . So that is what we have obtained from $z(t)$ here, that $z(t)$ is bounded by $e^{-\alpha t/2} K$ times norm of x_0 .

So we can say that from this inequality if we solve we can get that $z(t)$ is $\leq e^{-\alpha t/2} K$ times norm of x_0 here. So that is what we have achieved here $e^{-\alpha t/2} K$ times norm of x_0 . Now what is $x(t)$ here, so from this we can find out $x(t)$ is $e^{-\alpha t}$ times norm of $z(t)$ here. So norm of $x(t)$ is $\leq e^{-\alpha t}$ times norm of $z(t)$ and that we can write it here that K times norm of x_0 $e^{-\alpha t/2}$ you will get provided that norm of x_s is $\leq \beta$ but s is lying between 0 to t . So we can say that from this we can write it here.

That if so what we have achieved here let me write it here that norm of $x(t)$ is $\leq K$ times norm of x_0 $e^{-\alpha t/2}$ provided that norm of x_s is $\leq \beta$ where s is lying between 0 to t . Now here now our claim is that this will be automatically true if we assume that x_0 is \leq some quantity. Now here we can say that $e^{-\alpha t/2}$ is basically < 1 , so we can say that norm of $x(t)$ is $\leq K$ times norm of x_0 .

So if we choose our x_0 suitably then your x_s will be $< \beta$ for s lying between 0 to t here.

(Refer Slide Time: 21:01)

If $\|x(0)\| \leq \frac{\beta}{K}$, then $\|x(t)\| \leq \beta$ for $t \geq 0$. ✓

Therefore, this inequality is true for all $t \geq 0$ if $\|x(0)\| \leq \frac{\beta}{K}$. ✓

Finally we observe that $\|x(t)\| \leq K\|x(0)\|e^{-\frac{\alpha t}{2}}$ and therefore $\|x(t)\| \rightarrow 0$ as $t \rightarrow \infty$.
Hence the equilibrium solution $x(t) \equiv 0$ of (1) is asymptotically stable.

(b) The proof of (b) is quite lengthy and involving so we assume the proof without proving it here.

Handwritten notes in red ink:

- $\|x(t)\| \leq K \cdot \|x(0)\| \leq \frac{\beta}{K}$
- $\|x(t)\| \leq \beta$ ✓ $t \geq 0$
- $\|x(t)\| \leq K \|x(0)\| e^{-\frac{\alpha t}{2}}$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 14

So it means that if I choose that norm of x_0 is $< \beta/K$, then we can say that norm of $x(t)$ is \leq here we have written it is K times x_0 , so it is K times norm of x_0 here. So we

simply say that if $\|x_0\| < \beta/K$ then you can say that norm of $x(t)$ is $\leq \beta$ here β times norm of x_0 is $\leq \beta/K$, then your norm of $x(t)$ is $\leq \beta$ for all $t \geq 0$ here, so it means that the previous this inequality is always true for all $t \geq 0$ here.

So it means that the restriction that norm of x is $\leq \beta$ can be realized can be met if we assume that norm of x_0 is $\leq \beta/K$ because in this K norm of $x(t)$ is always $\leq \beta$ for $t \geq 0$. So this condition is now met automatically that norm of x is $\leq \beta$. So this if you say that norm of x_0 is $\leq \beta/K$ then norm of x of t is $\leq K$ times norm of $x_0 \cdot e^{-\alpha t/2}$ to power K times norm of x_0 $e^{-\alpha t/2}$.

So here this inequality is always true for all $t \geq 0$ if norm of x_0 is $< \beta/K$. So finally we observed that norm of $x(t)$ is $\leq K$ times norm of $x_0 e^{-\alpha t/2}$ and then we can say that norm of $x(t)$ is tending to 0 as t tending to infinity and hence we can say that the equilibrium solution $x=0$ is asymptotically stable solution. So this says that it is stable solution.

And then because of $e^{-\alpha t/2}$ term is here as t tending to infinity this term will vanish to will tend to 0 very fast and we can say that $x(t)$ will tend to 0 as t tending to infinity and hence we can say that $x(t) \equiv 0$ is an asymptotically stable solution. So what we have proved that if eigenvalues of A , if all the eigenvalues of A have negative real part then the solution zero solution of $\dot{x} = Ax + g(x)$ is asymptotically stable solution.

Now here regarding the proof of b, this proof is quite lengthy and involving. So here we can assume the proof without proving it here and so it means in this way we can say that we have done, we have considered all the cases, case a, case b and case c here. So now with this, we have completed the theorem. Now let us consider the application here. So in this proof, we have just discussed the stability of equilibrium solution which is $x=0$.

Now how we can utilize this theorem to discuss the stability of nonzero equilibrium solution. That we are going to discuss in next few slides. So now we say that this theorem 1 is also useful in determining the stability of equilibrium solution of arbitrary autonomous differential equation.

(Refer Slide Time: 25:01)

Theorem 1 is also useful in determining the stability of equilibrium solutions of arbitrary autonomous differential equations. Let x^0 be an equilibrium solution of the differential system

$$\frac{dx}{dt} = f(x) \quad (5)$$

$f(x^0) = 0$

and denote $z(t) = x(t) - x_0$. Then

$$\dot{z} = \frac{dx}{dt} = f(x^0 + z) \Rightarrow \dot{z}(t) = f(x^0 + z) \quad (6)$$

Clearly $z(t) \equiv 0$ is an equilibrium solution of (6) and the stability of $x(t) \equiv x^0$ is equivalent to the stability of $z(t) \equiv 0$.

$$z \equiv 0 \quad f(x^0) = g(z) = 0$$

$$\dot{z}(t) = f(x^0 + z) = Az + g(z)$$

So let x_0 be an equilibrium solution of the differential equation $dx/dt=f$ of x . Now this x_0 may not be a 0, if it is a 0 we have the result we can get it but if x_0 is nonzero let us see how we can say utilize our theorem 1 to discuss the stability of equilibrium solution here. So now we simply shift our origin and we simply write z as $x-x_0$ here. So using this now I can write \dot{z} as \dot{x} since x_0 is equilibrium solution, so \dot{x}_0 is simply 0.

So $\dot{z} = \dot{x}$. Now $\dot{z} = \dot{x}$ we can simply write dx/dt and dx/dt is already given as f of x . Now x can be replaced as $z+x_0$, so we can say that now we can have $\dot{z} = f$ of x_0+z here. Now what is the change in equation number 5 and this equation number 6 here, that here your equilibrium solution of 5 is x_0 , it means that f of x_0 is $=0$ here but if you look at the system 6 here if you say that $z=0$ is an equilibrium solution here because when you put z identically $=0$ then it is nothing but f of x_0 and we know that it is 0.

So it means that we are able to convert a problem where we have a nonzero equilibrium solution to a problem where we have 0 as an equilibrium solution here. So this is now converted into $\dot{z} = f$ of x_0+z . Now we can say that here this can be converted into a form which you have discussed earlier that is $\dot{z} = \dot{x}$, we want that if we impose certain condition on f here, then this f of x_0+z may be written as $Az + g(z)$ where Az is a linear part in z and $g(z)$ is something that $g(0)=0$.

And $g(z)/z$ is a continuous function of 0 and vanishes at $z=0$. So we need to find out a condition on f such that we may write it like this. So here let me write it here that clearly $z=0$

is an equilibrium solution of 6 and the stability of x^t identically $=x^0$ is equivalent to the stability of z^t identically $=0$ here.

(Refer Slide Time: 27:58)

So here we have the following lemma by which we can say that we can convert, we can write down the expression f of x^0+z as f of $x^0+Az+gz$ here where gz satisfy the property mentioned in the previous theorem that is $gz/\text{norm of } z$ is a continuous function of z and vanishes for $z=0$ here. So the condition we are putting on f is the following that let f_x have two continuous partial derivatives with respect to each of its variable x_1 to x_n .

Then, f of x^0+z may be rewritten as f of $x^0+z=f$ of x^0+Az+g of z here. Now I am giving you these are the sufficient condition we impose on f here. Here we may consider only that this thing that first-order partial derivative exist continuous and second-order partial derivative simply exists, then also we can write down f of $x^0+z=f$ of $x^0+Az+gz$ here. The following lemma this lemma has several proof.

We are just using one result we simply here we have written z dash $t=f$ of x^0+z here. Now we already know that this f of x^0 is $=0$ here. So I can write this as f of x^0 here right. Now since f of x^0+z-f of x^0 . Then, using your mean value theorem I can write this as f of $x^0+\text{some } \theta z$ here where θ is lying between 0 and 1 here and so here now so this can be written as z dash $t=f$ of $x^0+\theta z$.

Now here we are assuming sorry it is with respect to the derivative with respect to x here. Now sorry it is a function of z . So f_z $x^0+\theta z$ it is given here. Now we have assumed that

this has continuous partial derivative, so it means that this implies that let limit theta tending to 0, your $f_z(x_0 + \theta z)$ is nothing but $f_z(x_0)$ here, sorry it is z tending to 0. So limit z tending to 0 $f_z(x_0 + \theta z) = f_z(x_0)$ or I can write here $f_z(x_0 + \theta z) = f_z(x_0) + \text{some } g_z$ here.

Now this implies that g_z is tending to 0. So this implies that limit g_z is tending to 0 as g_z/z is tending to 0 as z is tending to 0 here. So this is one way to look at the say proof of this. Another way to write down the proof is using Taylor's theorem. Then, since f is what, f is $f(x_0 + z)$ is nothing but we can write it $f_1(x_0 + z)$ $f_2(x_0 + z)$ here and $f_n(x_0 + z)$ here. Now for each f_i we can write down say $f_i(x_0 + z)$ as your $f_i(x_0) + \text{now here we can write down } z_1 \frac{df_i}{dz_1} + z_2 \frac{df_i}{dz_2} + \dots + z_n \frac{df_i}{dz_n} + \dots$

Now this is nothing but okay and similarly we can write down for each $i, i=1$ to n here. So it means that I can write down let me write it here.

(Refer Slide Time: 32:35)

$$f_i(x_0 + z) = f_i(x_0) + z_1 \frac{\partial f_i}{\partial z_1} + z_2 \frac{\partial f_i}{\partial z_2} + \dots + z_n \frac{\partial f_i}{\partial z_n} + \dots$$

$$i=1, \dots, n$$

$$f(x_0 + z) = \begin{pmatrix} f_1(x_0) \\ \vdots \\ f_n(x_0) \end{pmatrix} + \begin{pmatrix} \frac{\partial f_1}{\partial z_1} & \dots & \frac{\partial f_1}{\partial z_n} \\ \vdots & & \vdots \\ \frac{\partial f_n}{\partial z_1} & \dots & \frac{\partial f_n}{\partial z_n} \end{pmatrix} \begin{pmatrix} z_1 \\ \vdots \\ z_n \end{pmatrix} + \dots$$

$$f(x_0 + z) = f(x_0) + Az + g(z)$$

That for each i $f_i(x_0 + z)$ is given as $f_i(x_0) + z_1 \frac{df_i}{dz_1} + z_2 \frac{df_i}{dz_2} + \dots + z_n \frac{df_i}{dz_n} + \dots$ and so on $z_n \frac{df_i}{dz_n} + \text{high order term}$. So this I can write it for each $i, i=1$ to say n . So we can simply say that in particular I can write f of $x_0 + z$ as this is $f_1(x_0) + \dots + f_n(x_0) + \text{now this let me write it here}$. This is what $\frac{df_1}{dz_1} + \dots + \frac{df_1}{dz_n}$ and to $\frac{df_n}{dz_1} + \dots + \frac{df_n}{dz_n} \cdot z_1$ to z_n here $+ \text{high order term}$.

Now high order term means involving the say squared terms of z_1, z_2 and z_n 's and multiple of this. So it means that here your g_z will be containing say polynomials in terms of z_i 's of degree more than 2 here. So this means that this is your f of x_0 here, this we denote as A and

this is z +whatever left is your $g(z)$ here. Now $g(z)$ contains say polynomial terms in terms of z_1 to z_n of degree 2 or more here.

So this is what we have written here x_0+z I can write it like this. So that is what is given here that if $f(x)$ have two second-order continuous special derivative with respect to each of its variable x_1 to x_n then f of x_0+z may be written as f of $x_0+z=f$ of $x_0+Az+g(z)$ here. So here we are not assuming anything on any condition on x_0 but if we assume that f of $x_0=0$ then we can do it by same mean value theorem also and the continuity properties here.

But here in general if $f(x)$ contains the, $f(x)$ has the second order continuous partial derivative then we can rewrite f of x_0+z as f of $x_0+Az+g(z)$ here. Now since f of x_0 is 0 then I can write this the previous problem z dash $t=f$ of x_0+z dash z where $g(z)$ contains the term in terms of z_1 to z_n with power 2 or higher. So here we can rewrite we can apply our theorem 1 for general nonlinear system also where we want to check the stability of an equilibrium solution x_0 here.

So with this we finish our lecture here and next lecture we will discuss some example based on this observation and discuss the stability of an arbitrary equilibrium solution and that we discuss in next lecture. Thank you very much for listening us. Thank you.
