**Phase Portrait of Linear Differential Equations - I**

Hello friends. Welcome to this lecture. In this lecture, we will continue with study of phase portrait. So in previous lectures, we have discussed what do you mean by phase portrait and we have discussed the different types of critical points. So in this lecture we will discuss more about phase portrait. In fact, we will focus on linear system of dimension 2 so that we can portrait the phase portrait on your xy plane.

And we also try to see that the critical point of the linear system is of what type. So for that, let us consider the following linear differential equation. So consider the linear system  $dx/dt=ax+by$ .

**(Refer Slide Time: 01:11)**

Linear Differential Equations

Consider the linear system

$$\begin{cases} \frac{dx}{dt} = ax + by \\ \frac{dy}{dt} = cx + dy \end{cases} \quad \begin{cases} \begin{pmatrix} \dot{x} \\ \dot{y} \end{pmatrix} = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix} \\ \begin{pmatrix} x \\ y \end{pmatrix} = e^{\lambda t} \begin{pmatrix} A \\ B \end{pmatrix} \end{cases} \quad (1)$$

where  $a, b, c,$  and  $d$  are real constants. The origin  $(0, 0)$  is clearly an equilibrium point of (1). Suppose

$$\begin{vmatrix} a & b \\ c & d \end{vmatrix} \neq 0$$

and hence  $(0, 0)$  is the only critical point of (1). Let the solutions of (1) be

$$x = Ae^{\lambda t}, \quad y = Be^{\lambda t} \quad (2)$$

IIT Roorkee  
NPTL ONLINE  
CERTIFICATION COURSE

2

And  $dy/dt=cx-dy$  where  $a, b, c, d$  are real constants. And here we can say that this system has  $0, 0$  as an equilibrium point. And if we impose one more condition that determinant of  $a \ b \ c \ d$  is non-0, then  $0, 0$  is the only critical point of this system 1 here. Now let us find out the solution of 1 here. So for that you simply assume that  $x=Ae$  to the power  $\lambda t$  and  $y=Be$  to the power  $\lambda t$  be 2 possible solution of this.

And then try to find out the solution of this. In fact, if you look at, here if I simply denote this  $x$  as vector, then it is nothing but your  $a$   $b$   $c$   $d$  and  $x$   $y$  it is written here. So it is a system like this and your solution which we are assuming is the following that  $x = e^{\lambda t}$  and  $y = e^{\lambda t}$  to the power  $\lambda$   $t$  and this  $A$  and  $B$  here. So here we need to find out this vector  $A$   $B$  and vector  $AB$  and the constant  $\lambda$  such that it will work as a solution here.

So that is why we have writing that  $x = Ae^{\lambda t}$  and  $y = Be^{\lambda t}$  to the power  $\lambda$   $t$  be the possible form of the solution. And we need to find out the condition, the values of  $A$   $B$  and the  $\lambda$ . So here we have already seen that this  $\lambda$  is the characteristic note of the matrix  $A$  and  $AB$  is the corresponding eigenvector for eigenvalue  $\lambda$  here.

**(Refer Slide Time: 03:02)**

For (2) to be a solution of (1),  $\lambda$  must satisfy

$$\lambda^2 - (a + d)\lambda + (ad - bc) = 0, \quad (3)$$

called the characteristic equation of (1). Let  $\lambda_1$  and  $\lambda_2$  be the roots of the characteristic equation (3). We claim that the nature of the fixed point depends upon the nature of the roots  $\lambda_1$  and  $\lambda_2$ . For, we must consider the following five cases where  $\lambda_1$  and  $\lambda_2$  are

- ✓ 1 real, unequal and of the same sign.  $\lambda_1 + \lambda_2$
- ✓ 2 real, unequal and of the opposite sign.  $\lambda_1 - \lambda_2$
- ✓ 3 real and equal.
- ✓ 4 conjugate complex but not purely imaginary.
- ✓ 5 purely imaginary.

(0,0)

IT ROOFKEE | NPTEL ONLINE CERTIFICATION COURSE | 3

So for that, look at here. Then for 2 to be a solution of 1,  $\lambda$  must satisfy this equation that is  $\lambda^2 - a + d \lambda + ad - bc = 0$  which is nothing but the characteristic equation of 1 in terms of  $\lambda$  here. So here we call this equation number 3 as the characteristic equation of 1. And since it is a quadratic equation, then there is a possibility of having 2 roots  $\lambda_1$  and  $\lambda_2$ .

So let  $\lambda_1$  and  $\lambda_2$  be the roots of the characteristic equation 3. And we claim that the nature of the fixed points that is  $(0, 0)$  depends upon the nature of the roots of  $\lambda_1$  and  $\lambda_2$ . So here we already know that  $(0, 0)$  is a critical point or say equilibrium point or

stationary point or fixed point. And the type of the critical point whether it is say node or say stable node, unstable node, focus, spiral, it will all depend on the behaviour of  $\lambda_1$  and  $\lambda_2$ .

So based on the root,  $\lambda_1$  and  $\lambda_2$ , we have following 5 cases and we will consider each and every case and based on each case, based on the conditions given in each case, we try to find out the behaviour of  $(0, 0)$  whether  $(0, 0)$  is what kind of critical point. So first case based on  $\lambda_1$  and  $\lambda_2$  is that both  $\lambda_1$  and  $\lambda_2$  are real, unequal and of the same sign.

So it means that here  $\lambda_1$  is not equal to  $\lambda_2$  but the sign is same whether, it means that both may be positive or both may be negative. And the second case is real, unequal but in this case, they are having opposite sign. So it means  $\lambda_1$  is not equal to  $\lambda_2$  and it may happen that  $\lambda_1$  is positive but  $\lambda_2$  is negative and it may be the otherwise also. So this is the case 1 and 2.

Here  $\lambda_1$  is not equal to  $\lambda_2$ . One is that they are having the same sign and the other case is they are having the opposite sign. Now third case that they are real and equal. So it means that the first 2 case are corresponding to unequal roots and the third case is corresponding to equal. So 1, 2, 3, they are all real.  $\lambda_1$  and  $\lambda_2$  both are all real. And it may be unequal or equal.

And the fourth case and fifth case are corresponding to the case when  $\lambda_1$  and  $\lambda_2$  are complex. So they are not real. So again, in complex, we have 2 subcases, that is conjugate complex but not purely imaginary. So it means that they are having both real part as well as the imaginary part. And fifth case is corresponding to purely imaginary part. So it means that real part is missing here.

So these are the 5 cases and based on each case, we have 1 theorem which tells us that under these condition, the behaviour of  $(0, 0)$  is what.

**(Refer Slide Time: 06:25)**

**Theorem 1**

**Theorem** The roots  $\lambda_1$  and  $\lambda_2$  of the characteristic equation (3) are real, unequal, and of the same sign.

Then the critical point  $(0, 0)$  of the linear system (1) is a node.

**Proof.** We first assume that  $\lambda_1$  and  $\lambda_2$  are both negative and take  $\lambda_1 < \lambda_2 < 0$ .

The general solution of (1) may then be written

$$\begin{aligned} x &= c_1 u_1 e^{\lambda_1 t} + c_2 v_1 e^{\lambda_2 t} \\ y &= c_1 u_2 e^{\lambda_1 t} + c_2 v_2 e^{\lambda_2 t} \end{aligned}$$

where  $u_1, u_2, v_1,$  and  $v_2$  are definite constants and  $u_1 v_2 \neq v_1 u_2$ , and where  $c_1$  and  $c_2$  are arbitrary constants. Choosing  $c_2 = 0$  we obtain the solutions

$$\begin{aligned} x &= c_1 u_1 e^{\lambda_1 t} \\ y &= c_1 u_2 e^{\lambda_1 t} \end{aligned} \quad (5)$$

So let us consider the first theorem which corresponding to the case 1. So here the theorem says that the roots  $\lambda_1$  and  $\lambda_2$  are of characteristic equation 3 are real, unequal and of the same sign, right. Then the critical point  $0, 0$  of the linear system 1 is a node. So here the case 1 which is for  $\lambda_1$  and  $\lambda_2$ , both are real, unequal and of the same sign. Then the critical point  $0, 0$  is a node.

Now whether it is a stable node or unstable node, that will depend on the sign of  $\lambda_1$  and  $\lambda_2$ . So first let us assume that  $\lambda_1$  and  $\lambda_2$  are both negative and let us assume this that  $\lambda_1 < \lambda_2 < 0$ . Since they are real and unequal, so we have, we can take this condition  $\lambda_1 < \lambda_2 < 0$ . So here we, just for simplicity, we are assuming that  $\lambda_1 < \lambda_2$  and greater than 0.

So it may be otherwise also. Now in this case, your solution of 1 may be written as  $x = c_1 u_1 e^{\lambda_1 t} + c_2 v_1 e^{\lambda_2 t}$  and  $y = c_1 u_2 e^{\lambda_1 t} + c_2 v_2 e^{\lambda_2 t}$ . In fact, in this case when your dimension is 2 and we have 2 distinct eigenvalues, then we have 2 distinct eigenvectors, this we have already run. So let us call this as  $v$  and  $u$  are 2 eigenvectors.

So  $u$  is given as  $u_1$  and  $u_2$  and  $v$ , I am writing as  $v_1$  and  $v_2$  here. So let me write down the solution here. Solution  $xy$  is given as  $c_1 e^{\lambda_1 t}$ . Now corresponding to  $\lambda_2$

1, we have eigenvectors say  $u_1 u_2 + c_2 e$  to the power  $\lambda_2 t$  and corresponding to  $\lambda_2$ , we have  $v_1$  and  $v_2$  here. So when you simplify, you will get what?  $x = c_1 e$  to the power  $\lambda_1 t + c_2 e$  to the power  $\lambda_2 t$ .

Similarly, y, I can write it,  $c_1 e$  to the power  $\lambda_1 t + c_2 v_2 e$  to the power  $\lambda_2 t$  here. So the solution, form of the solution is given from this, okay. So here, this  $u_1 u_2 v_1 v_2$  are some constants and here we are assuming that  $u_1 v_2$  is not equal to  $v_1 u_2$ . So that is very obvious from here because here  $v$  and  $u$  are linearly independent to each other. So it means that I cannot write  $v$  as some constant multiple of  $u$  here.

So it means that, so  $v$  cannot be written as constant multiple of  $u$  means, let us take  $v_1 v_2$  as say  $k^*$ , say,  $u_1$  and  $u_2$ . And we can say that this is, this condition is easily verified here. And now here, since  $c_1$  and  $c_2$  are some arbitrary constants and we can write down the general solution as  $xy$  here. Here now we consider different cases corresponding to this  $c_1$  and  $c_2$ . So now let us assume that  $c_2 = 0$ .

So when  $c_2 = 0$ , then we have the solution  $x = c_1 u_1 e$  to the power  $\lambda_1 t$ ,  $y$  as  $c_2 u_2 e$  to the power  $\lambda_2 t$  or I can say that it is nothing but  $xy =$ , say  $c_1$  and here we have  $u_1$  and  $u_2$  and  $e$  to the power  $\lambda_1 t$  here, right.

**(Refer Slide Time: 10:19)**

Choosing  $c_1 = 0$  we obtain the solutions

$$x = c_2 v_1 e^{\lambda_2 t}$$

$$y = c_2 v_2 e^{\lambda_2 t}.$$

For any  $c_1 > 0$ , the solutions (5) represents a path consisting of "half" of the line  $u_2 x = u_1 y$  of the slope  $u_2/u_1$ . For any  $c_1 < 0$ , the solutions (5) represents a path consisting of "other half" of this line. Since  $\lambda_1 < 0$ , both of these half-line paths approach  $(0, 0)$  as  $t \rightarrow +\infty$ . Also, since  $y/x = u_2/u_1$ , these two paths enter  $(0, 0)$  with slope  $u_2/u_1$ .

IT ROOPKEE    NPTEL ONLINE CERTIFICATION COURSE    5

So now similarly, choosing  $c_1=0$ . Here we have assumed  $c_2=0$ , so we have solution like this. And if we assume that  $c_1=0$ , then your solution will be  $xy=c_2$ , here we have  $v_1$  and  $v_2$  to the power  $\lambda 2t$ , right. So now once we have, this is corresponding to  $c_1=0$ . And the earlier one is corresponding to  $c_2=0$ . Now here consider this case when  $c_2=0$ , but  $c_1$  is non-0, then  $c_1$  may be positive and  $c_2$  may be negative here.

So here if we consider that  $c_1$  is positive, then this  $u_1$  and  $u_2$  simply represent a vector here and we can write here that, let us consider this. So  $u_1$   $u_2$  represent a point here somewhere, right. So now this  $c_1 u_1 u_2 e$  to the power  $\lambda 1t$  is basically, this is your  $u_1$   $u_2$ . Now  $c_1$  is just a scaling vector and  $e$  to the power  $\lambda 1t$  is some scaling vector. So it will give you some point on this line.

So it means that this will represent a line passing through the point  $u_1$  and  $u_2$  here, right. And it is passing through this. Similarly, if you look at this, this may represent, suppose  $v_1 v_2$  is somewhere here,  $v_1$ ,  $v_2$  here. And this line represent the vector  $v_1$  and  $v_2$ . And if  $c_2$  is positive, then it will represent the line like this. And the earlier one line is like this. Now if  $c_1$  is negative, then this will be here and if  $c_2$  is negative, then this will be here, right.

So it means that when  $c_2=0$ , then depending on  $c_1$ , whether  $c_1$  is positive, then it will represent this line. And if  $c_1$  is negative, this will represent this line. And similarly, when  $c_1=0$ , then it will be along your vector  $v_1$  and  $v_2$  and  $c_2$  positive will give you this line and  $c_2$  negative will give you this line. So it means that for any  $c_1 > 0$ , the solution 5 represent a path consisting of half of the line  $u_2 x = u_1 y$ .

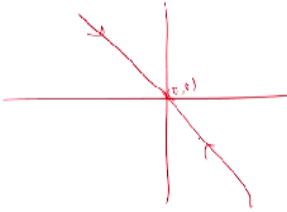

So this line is equation is given by  $xy=$ , say,  $u_1$  and  $u_2$ . So we can write down this line as  $u_2 x - u_1 y$ . And the slope is given by  $u_2/u_1$ . So this line has a slope given by  $u_2/u_1$  here, right. Now for any  $c_1 < 0$ , the solution 5 represent a path consisting of the other half, like other half, this. Now here, one thing we may note down that  $\lambda 1$  is negative. So it means that as  $\lambda 1$  is negative, so as  $t$  tending to infinity, your  $xy$  is tending to 0 along the line given by this  $u_2 x$  and  $u_1 y$ .

So it means that as  $t$  tending to infinity and  $c_2$  is 0, then your solution will tend to  $(0, 0)$  here along the line this with slope  $u_2/u_1$ , right. So it means that your solution will come to here. Now similarly, we can say that solution will tend to  $(0, 0)$  if  $c_1$  is negative and as  $t$  tending to infinity, solution will tend to origin through on this line itself.

So we simply say that both of these half line paths approach  $(0, 0)$  as  $t$  tending to infinity. Now we already know that  $y/x = u_2/u_1$ , so these 2 paths enter  $(0, 0)$  with the slope  $u_2/u_1$  here. So it means that as  $t$  tending to infinity, your solution will enter origin  $(0, 0)$  as  $t$  tending to infinity with the slope  $u_2/u_1$  here.

**(Refer Slide Time: 14:46)**

In like manner, for any  $c_2 > 0$  the solutions (6) represent a path consisting of "half" of the line  $v_2x = v_1y$ ; while for any  $c_2 < 0$ , the path so represented consists of the "other half" of this line. These two half-line paths also approach  $(0, 0)$  as  $t \rightarrow +\infty$  and enter it with slope  $v_2/v_1$ .

NPTEL ONLINE CERTIFICATION COURSE

Now the other, in the same manner, we can say that this is your line, right. So here also, your solution will enter to origin with the slope  $v_2/v_1$  in the same way. So if  $c_2$  is positive, then it will come through this line. If  $c_2$  is negative, then it will come through this line, right. So it means that solution will enter  $(0, 0)$  along a particular line with the given slope, right.

**(Refer Slide Time: 15:22)**

Thus the solutions (5) and (6) provide us with four half-line paths which all approach and enter  $(0, 0)$  as  $t \rightarrow +\infty$ .

If  $c_1 \neq 0$  and  $c_2 \neq 0$ , the general solution (4) represents non-rectilinear paths.

Again, since  $\lambda_1 < \lambda_2 < 0$ , all of these paths approach  $(0, 0)$  as  $t \rightarrow +\infty$ . Further, since

$$\frac{y}{x} = \frac{c_1 u_2 e^{\lambda_1 t} + c_2 v_2 e^{\lambda_2 t}}{c_1 u_1 e^{\lambda_1 t} + c_2 v_1 e^{\lambda_2 t}} = \frac{(c_1 u_2 / c_2) e^{(\lambda_1 - \lambda_2)t} + v_2}{(c_1 u_1 / c_2) e^{(\lambda_1 - \lambda_2)t} + v_1}$$

we have

$$\lim_{t \rightarrow \infty} \frac{y}{x} = \frac{v_2}{v_1}$$

and so all of these paths enter  $(0, 0)$  with limiting slope  $v_2/v_1$ .

Now let us assume that, so it means that the solution 5 and 6 provide us the 4 half line path which all approach and enter as  $t$  tending to  $+\infty$ . Now let us assume that none of the constants  $c_1$  and  $c_2$  are 0. So it means that if  $c_1$  and  $c_2$  are non-0, then the general solution 4 represents non-rectilinear path. Means your  $x$  is written as  $c_1 u_1 e$  to the power  $\lambda_1 t + c_2 v_1 e$  to the power  $\lambda_2 t$  and  $y$  is written as  $c_1 u_2 e$  to the power  $\lambda_1 t + c_2 v_2 e$  to the power  $\lambda_2 t$ .

So again, since  $\lambda_1 < \lambda_2 < 0$ , all of these path approach  $0, 0$  as  $t$  tending to infinity but not along the given half line path. So let us find out that whether it will enter to origin  $0, 0$  along some line or not. So for that, you just find out the slope  $y/x$  here. So  $y$  expression is given,  $x$  expression is given, so you simply find out the ratio of  $y/x$  and ratio of  $y/x$  is given by  $c_1 u_2 e$  to the power  $\lambda_1 t + c_2 v_2 e$  to the power  $\lambda_2 t / c_1 u_1 e$  to the power  $\lambda_1 t + c_2 v_1 e$  to the power  $\lambda_2 t$ .

Now since  $\lambda_1 < \lambda_2$ , so let us divide by  $e$  to the power  $\lambda_2 t$ . So when you divide by  $e$  to the power  $\lambda_2 t$ , you will get this  $c_1 u_2 + c_2 e$  to the power  $\lambda_1 - \lambda_2 t + v_2$  and  $c_1 u_1 / c_2 e$  to the power  $\lambda_1 - \lambda_2 t + v_1$ . Now as  $t$  tending to infinity, this quantity is now negative. So this term will tend to 0, this term will tend to 0. So limit of  $t$  tending to infinity  $y$  of  $x$  is given by  $v_2/v_1$  here.

Now what is  $v_2$  and  $v_1$ ? Basically it is an eigenvector corresponding to the eigenvalue  $\lambda_2$  here. So here, let me look at here. Here, yes, this  $v_1$  and  $v_2$  is the eigenvector corresponding to  $\lambda_2$ . So here we simply say that you look at this line. So this is the line corresponding to  $\lambda_1$  and the eigenvector  $u_1$  and  $u_2$ . So slope is  $u_2/u_1$ , the inverse of  $u_2/u_1$ . And similarly, this is the line which is having slope  $v_2/v_1$ .

So it is having the slope  $v_2/v_1$  and it is passing through  $v_1, v_2$ , right. So we already know this thing. Now it is seen that if we take any path and consider the path  $t$  tending to infinity, then this represents that your solution will tend to  $0, 0$ , approach to  $0, 0$  along the line this, right. And since it has a definite slope, so we say that your every solution will enter  $0, 0$  with limiting slope  $v_2, v_1$ .

So it means that if we consider a solution which is starting from this, then ultimately as  $t$  tending to infinity, it will try to come to  $0, 0$  and towards the line having slope  $v_2, v_1$ . So if we have some point here, it will try to come to something like this. And similarly here, if we have any path and it will try to tend to  $0, 0$  along this line, along these half lines. So if we have a point starting from this, it will try to have, say tend to origin along the line this, right.

So if we consider the situation, this is the eigenvector corresponding to  $\lambda_1$  and this is the eigenvector corresponding to  $\lambda_2$ . And since  $\lambda_2$  is bigger than  $\lambda_1$ , then solution will tend to origin along the eigenvector corresponding to  $\lambda_2$ . So it means that this is the eigenvector, this is the line corresponding to the eigenvector  $v_1, v_2$  here. Is that okay? So it means that in this case, your origin  $0, 0$  is a stable node because all the solution is tending to  $0, 0$ .

In fact, entering to  $0, 0$  along a line, it means having a limiting slope  $v_2, v_1$  here. So we can say that origin  $0, 0$  is node. In fact, it is stable node or we can say since it is entering  $0, 0$ , so it is asymptotically stable node. So in this case, when  $\lambda_1$  and  $\lambda_2$ , both are real, unequal and negative, then solution will tend to  $0, 0$  and enter  $0, 0$ . So in this case, origin is asymptotically stable node.

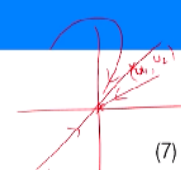

So thus in summary, we can say that thus all the path both rectilinear and non-rectilinear, rectilinear means along the straight lines. And non-rectilinear means along the curves. Enters 0, 0 as t tending to +infinity and all except the 2 rectilinear ones defined by 4 and enter with slope  $v_2/v_1$ , according to the definition, the critical point 0, 0 is a node and clearly it is asymptotically stable node here.

So this is the statement theorem 1. And let us consider one example based on this. So rather phase portrait for the linear system  $y_1' = -3y_1 + y_2$ ,  $y_2' = y_1 - 3y_2$ . And here we can identify that 0, 0 is the critical point and then now look at the determinant of the linear part, that is  $-3 \ 1 \ 1 \ -3$  and you can see that determinant is coming out to be non-0.

**(Refer Slide Time: 22:14)**

**Example 1**

Draw the phase portrait for the linear system

$$\begin{aligned} y_1' &= -3y_1 + y_2 \\ y_2' &= y_1 - 3y_2 \end{aligned} \quad (7)$$

**Solution:** Clearly (0, 0) is the only critical point of the given linear system as

$$\begin{vmatrix} -3 & 1 \\ 1 & -3 \end{vmatrix} = 8 \neq 0$$

The characteristic equation of the given differential equation is given by

$$\begin{vmatrix} -3 - \lambda & 1 \\ 1 & -3 - \lambda \end{vmatrix} = 0 \Rightarrow \lambda_1 = -2 \text{ and } \lambda_2 = -4.$$

Since, both the eigen-values are real and negative, the critical point (0,0) of the given system is a node and it is asymptotically stable.

NPTEL ONLINE  
CERTIFICATION COURSE

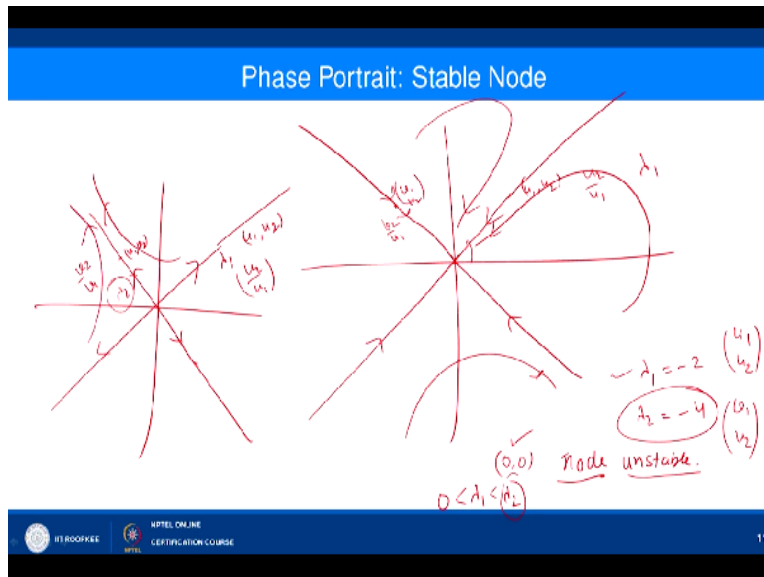

10

So since determinant is non-0, so we can say that 0, 0 is the only critical point. Now let us look at the eigenvalue corresponding to this linear matrix. So matrix is  $-3-\lambda \ 1 \ 1 \ -3-\lambda$  and we can find out the eigenvalues as  $\lambda_1 = -2$  and  $\lambda_2 = -4$ . So both are unequal and real and negative. So it means that we can apply the previous theorem and we can say that the critical point 0, 0 is node and it is asymptotically stable.

So it means that solution will tend to 0, 0 along a slope corresponding to this  $\lambda_1 = -2$ . So here I can write it  $\lambda_2 < \lambda_1 < 0$  here. So here we need to find out that it will, so corresponding to  $\lambda_1$ , if it is the eigenvector, so eigenvector corresponding to this means  $u_1$

and  $u_2$ . So it is passing through  $u_1$  and  $u_2$ . So it means that your solution will ultimately enter to 0 along this line. Is that okay? So the phase portrait will be like this and the critical point  $0, 0$  is a node and which is asymptotically stable node.

**(Refer Slide Time: 23:50)**

Now this is the phase portrait we can draw here. So let us say we have  $\lambda_1 = -2$ ,  $\lambda_2 = -4$  and let us say that  $\lambda_1$ , corresponding to  $\lambda_1$  we have  $u_1$  and  $u_2$  as the eigenvector and corresponding to  $\lambda_2$ , we have  $v_1, v_2$  as the eigenvector. So let us first find out  $u_1$  and  $u_2$ . Let us say that  $u_1$  and  $u_2$  here, you can find out  $u_1$  and  $u_2$ . So this is the line which represents, line segment which represents the eigenvector corresponding to  $\lambda_2 = -2$ .

So it means that now line segment you simply extend which continue  $u_1, u_2$ . And this will represent the half lines having the slope  $u_2, u_1$ . And similarly, we can have  $v_1$  and  $v_2$ . Let us say  $v_1$  and  $v_2$  is here. I am just giving a pictorial representation. You can actually find out the values of  $u_1$  and  $u_2$  and you can draw it here. So here suppose your  $v_1$  and  $v_2$  is here. So this will represent eigenvector.

And if you extend these line segment here, then it will represent the line segment having the slope  $v_2, v_1$  here, right. And along this also, your solution will tend to  $0, 0$  here. So here the slope of this is  $v_2/v_1$  and slope here is  $u_2/u_1$ , right. And these are the line segment and since this is corresponding to your  $\lambda_1$ , so your solution will ultimately tend to 0 along this line,

okay. So somewhere we have a solution and it will tend to 0, 0 along the line this. Is that okay?  
 So here we have a, the origin is asymptotically stable node.

(Refer Slide Time: 25:46)

**Theorem 2**

**Theorem** The roots  $\lambda_1$  and  $\lambda_2$  of the characteristic equation (3) are real, unequal, and of the opposite sign.

Then the critical point  $(0, 0)$  of the linear system (1) is a saddle point.

**Proof.** We assume that  $\lambda_1 < 0$  and  $\lambda_2 > 0$ . Recall the general solution of (1)

$$\begin{aligned} x &= c_1 u_1 e^{\lambda_1 t} + c_2 v_1 e^{\lambda_2 t} \\ y &= c_1 u_2 e^{\lambda_1 t} + c_2 v_2 e^{\lambda_2 t} \end{aligned}$$

and particular solutions of the forms (5) and (6).

$$\begin{aligned} x &= c_1 u_1 e^{\lambda_1 t}, & y &= c_1 u_2 e^{\lambda_1 t} \quad (c_2 = 0) \\ x &= c_2 v_1 e^{\lambda_2 t}, & y &= c_2 v_2 e^{\lambda_2 t} \quad (c_1 = 0). \end{aligned}$$

For any  $c_1 > 0$ , the solutions (5) again represents a path consisting of "half" of the line  $u_2 x = u_1 y$ ; while for any  $c_1 < 0$ , they again represent a path consisting of "other half" of this line.

Now consider next theorem, theorem 2. Here the roots  $\lambda_1$  and  $\lambda_2$  of the characteristic equation 3 are real, unequal and of the opposite sign. Now one more thing which I have missed here in the previous lecture that here what happens if  $\lambda_1$  and  $\lambda_2$ , both are real, unequal but positive. So in that case, the only difference is your sign will be reversed.

Because in that case,  $(0, 0)$  is the repulsive point. It means that all the solution will tend to infinity, say going away from origin  $(0, 0)$ . So in that case, your  $(0, 0)$  will be node but in this case, it is unstable node. So this is the case corresponding to  $\lambda_1 < \lambda_2$  and it is greater than 0. So in this case, your node, origin will remain the node but in this case, it is unstable and the phase portrait will look like exactly the same.

The only thing is that now solution will move towards the infinity along the, say other sign. So it means that it is moving away along the line, say having the slope  $u_2/u_1$  and it will go towards infinity along the other line corresponding to  $\lambda_2$  equal to the bigger one. So corresponding to, say  $\lambda_2$  here. So it means that it will tend to infinity along this line. Is that okay? So let me write it here.

So corresponding to this, we have this line. So this is corresponding to  $\lambda_1$  and we have your  $u_1, u_2$  on this line and slope of this line is  $u_2/u_1$  and this is corresponding to  $\lambda_2$  and slope is  $v_2/v_1$  and  $v_1$  and  $v_2$  are 2 points running on this. And now all solutions are moving away from origin and now it will, this  $\lambda_2$  is bigger than  $\lambda_1$ . So as  $t$  tending to infinity, the component corresponding to  $\lambda_2$  is bigger.

So it means that all the solution will go to infinity along this line. Is that okay? So here your origin  $0, 0$  is node but unstable node, right. Now move on to theorem 2. So the roots  $\lambda_1$  and  $\lambda_2$  of the characteristic equation 3 are real, unequal and of the opposite sign. So in the previous case, it was of the same sign. And then this case, critical point  $0, 0$  of the linear system is a saddle point.

So it means that if eigenvalues are opposite in sign, then we call origin a critical point as a saddle point. So in the same way, we recall the general solution as  $x=c_1u_1e^{\lambda_1 t}+c_2v_1e^{\lambda_2 t}$ ;  $y=c_1u_2e^{\lambda_1 t}+c_2v_2e^{\lambda_2 t}$ . And the particular solution in the case when  $c_2=0$ , we call  $x=c_1u_1e^{\lambda_1 t}$ ,  $y=c_1u_2e^{\lambda_1 t}$  and similarly, in the case corresponding to  $c_1=0$ .

So in this case, we can simply write it that you have  $\lambda_1$  and  $\lambda_2$ . Since these are unequal, so it means that we have say  $u$  eigenvector and  $v$  eigenvector. So  $u$  and  $v$  are linearly independent eigenvectors, right. And let us say this  $u$  is given by  $u_1, u_2$  and  $v$  is given by  $v_1$  and  $v_2$ . And the line, this is the line corresponding to  $u_1, u_2$  which contain this vector  $u_1, u_2$  and slope is  $u_2/u_1$  and this line is passing through the point  $v_1, v_2$  with the slope  $v_2/v_1$  here.

And depending on the  $c_1$  and  $c_2$ , it will be this thing. Now here, we are assuming that  $\lambda_1 < 0$  and  $\lambda_2 > 0$ . So it means that if you look at the component  $x$  here, which is corresponding to  $c_2=0$ , so since  $\lambda_1 < 0$ , your  $x$  will tend to 0, right. So it means that  $x$  is tending to 0 but  $y$  is tending to say infinity, I am sorry.  $x$  and  $y$  tending to 0 along the line  $c_2=0$ . So it means that here solution will tend to origin as  $t$  tending to infinity.

Now as  $\lambda_2 > 0$ , so in this case when  $c_1=0$ , your  $x$  and  $y$ , both are tending to infinity. So it

means that it will move away along the line passing through  $v_1, v_2$  here. Is that okay? So it means that for any  $c_1$  positive, the solution 5 again represent a path consisting of half of the line  $u_2x=u_1y$  while for any  $c_1 < 0$ , they again represent the path consisting of the other half of this line.

**(Refer Slide Time: 31:17)**

Once again, if  $c_1 \neq 0$  and  $c_2 \neq 0$ , the general solution (3) represents nonrectilinear paths. But here since  $\lambda_1 < 0 < \lambda_2$ , none of these paths can approach  $(0, 0)$  as  $t \rightarrow +\infty$  or as  $t \rightarrow -\infty$ . Further, none of them pass through  $(0, 0)$  for any  $t_0$  such that  $-\infty < t_0 < \infty$ . As  $t \rightarrow +\infty$ , we see from (3) that each of these non-rectilinear paths becomes asymptotic to one of the half-line paths defined by (5). As  $t \rightarrow -\infty$ , each of them becomes asymptotic to one of the paths defined by (5).

So since  $\lambda_1 < 0$ , both of these half line path approach and enter  $0, 0$  as  $t$  tending to infinity. So as we have pointed out here, the solution will enter to  $0, 0$  as  $t$  tending to infinity depending on the behaviour of  $c_1$  whether the  $c_1$  is positive or  $c_1$  is negative here. Now for any  $c_2 > 0$ , the solution 6 represents a path consisting of half of the line  $v_2x=v_1y$ , that is this line here. This line is  $v_2x=v_1y$ .

And for any  $c_2 < 0$ , the path which they represent consist of the other half of this line. But in this case, since  $\lambda_2 > 0$ , both of these half lines now approach and enter  $0, 0$  as  $t$  tending to  $-\infty$ , right. So in this case, it will enter  $0, 0$  as  $t$  tending to  $-\infty$ . So it means that as  $t$  tending to infinity, they are moving away from origin. So we are putting like this. So once again if  $c_1$  and  $c_2$ , both are non-negative, then general solution 3 represents non-rectilinear paths.

But since  $\lambda_1 < 0 < \lambda_2$ , none of these path can approach  $0, 0$  as  $t$  tending to  $+\infty$  or  $t$  tending to  $-\infty$ . And none of them pass through  $0, 0$  for any  $t_0$  such that  $t_0$  is lying between  $-\infty$  to infinity, right. As  $t$  tending to infinity, we see that each of these non-rectilinear path

become asymptotically to one of the line paths defined by 5. As  $t$  tending to  $-\infty$ , each of them becomes asymptotic to one of the paths defined by 5 here.

**(Refer Slide Time: 33:02)**

Thus there are two half-line paths which approach and enter  $(0,0)$  as  $t \rightarrow +\infty$  and two other half-line paths which approach and enter  $(0,0)$  as  $t \rightarrow -\infty$ . All other paths are non-rectilinear paths which do not approach  $(0,0)$  as  $t \rightarrow +\infty$  or as  $t \rightarrow -\infty$ , but which become asymptotic to one or another of the four half-line paths as  $t \rightarrow +\infty$  and  $t \rightarrow -\infty$ . According to the description and definition, the critical point  $(0,0)$  is a saddle point. Clearly, it is unstable.

$\lambda_1 \neq \lambda_2$   
 $\lambda_1, \lambda_2 < 0$

$(0,0)$

15

So it means that if you look at here, we have a path line like this. So it is solution are tending to origin along this line and moving away from this. So if you take any point here, solution starting from this, then it will try to come to origin along this line but as it is near to origin, then it will tend away from  $0,0$  along this line, right. So it is coming along the line this which is tending towards origin  $0,0$  and as it is near little bit origin, near to  $0,0$ , it will move away from  $0,0$  along the other line, right.

So in a similar way, if we have this thing, then it will behave like this and here it is like this, here it is like this. So none of the path, none of the solution is tending towards  $0,0$  here. So thus there are 2 half line paths which approach and enter  $0,0$  as  $t$  tending to infinity. These are half line paths. So one half line path is tending to origin and other half line path are moving away from origin, right.

All other paths are non-rectilinear path which do not approach  $0,0$  as  $t$  tending to  $+\infty$  or as  $t$  tending to  $-\infty$ . But which become asymptotic to one or another of the 4 half line paths as  $t$  tending to  $+\infty$  and  $t$  tending to  $-\infty$ . So according to the definition, the critical point  $0,0$  is a saddle point. And saddle point is always a unstable point. So in this case,  $0,0$ , the case is

what? When  $\lambda_1$  and  $\lambda_2$  are not equal and having opposite signs, that is  $\lambda_1$  and  $\lambda_2$  are less than 0.

So when product is less than 0 and  $\lambda_1$  and  $\lambda_2$  are real and unequal, then in this case (0, 0) is a saddle point and unstable point.

**(Refer Slide Time: 35:19)**

The slide is titled "Example 2" and contains the following text and equations:

Draw the phase portrait for the linear system

$$\begin{aligned}y_1' &= y_1 \\ y_2' &= -y_2.\end{aligned}$$

**Solution:** (0,0) is the only critical point of the given linear system as

$$\begin{vmatrix} 1 & 0 \\ 0 & -1 \end{vmatrix} = -1 \neq 0.$$

The characteristic equation of the given differential equation is given by

$$\begin{vmatrix} 1 - \lambda & 0 \\ 0 & -1 - \lambda \end{vmatrix} = 0 \Rightarrow \lambda_1 = 1 \text{ and } \lambda_2 = -1.$$

Thus, both the eigen-values are real and of opposite sign, the critical point (0,0) of the given system is a saddle point and it is unstable.

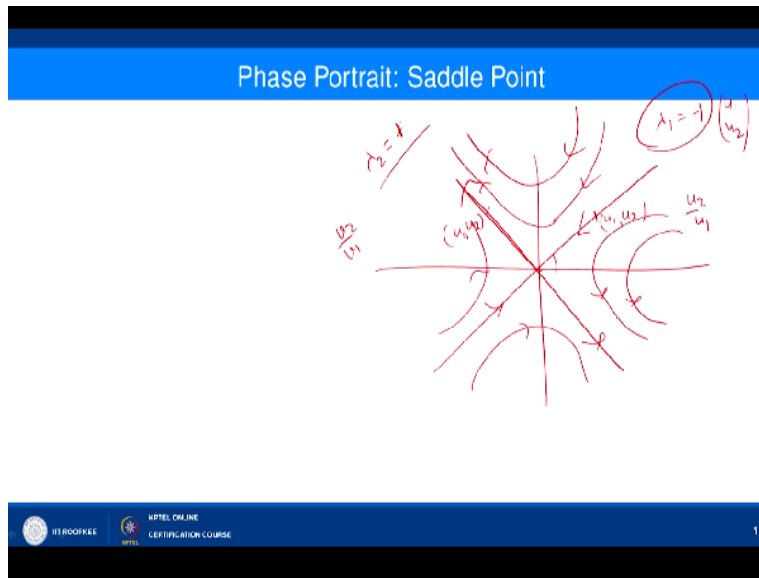

At the bottom of the slide, there are logos for IIT ROORKEE and NPTEL ONLINE CERTIFICATION COURSE, and the number 16 in the bottom right corner.

So now let us consider one example based on this. Draw the phase portrait for the linear system  $y_1' = y_1$  and  $y_2' = -y_2$ . So we can see that (0, 0) is the only critical point and we can check that the determinant is -1, so we can simply check. Now the characteristic equation of the given differential equation is given by  $\lambda^2 - 1 = 0$ , which gives the roots  $\lambda_1 = 1$  and  $\lambda_2 = -1$ .

So both are real, unequal and having opposite sign. So in this case, the critical point (0, 0) is saddle point and it is unstable here.

**(Refer Slide Time: 35:59)**

And the graph or the phase portrait, let us say that this is the eigenvector corresponding to, so this is the eigenvector corresponding to say  $\lambda_1 = -1$  and this is the  $\lambda_2 = +1$ . So corresponding to this, we have an eigenvector say  $u_1$  and  $u_2$ . So let us say this is the point  $u_1, u_2$  or we can say the line passing through  $u_1, u_2$  with the slope  $u_2, u_1$  here. Similarly, this is the line passing through origin  $0, 0$  and passing through  $v_1, v_2$  and the slope is  $v_2, v_1$  here, right.

So here since  $\lambda_1$  is negative, so solution will tend to origin as  $t$  tending to infinity. And since this is corresponding to positive eigenvalues, so it means the solution will move away from origin as  $t$  tending to  $+\infty$  or we can say that solution will tend to  $0$  as  $t$  tending to  $-\infty$ , okay. So now these are 4 rectilinear paths and for non-rectilinear paths, you should take any solution, then it will tend towards origin along this line and as it is near to origin, then it will move away from origin along the other line here.

So your phase portrait will be like this, something like this. So this is the phase portrait of saddle point and so here we stop. So in this we have considered case corresponding to that eigenvalues are real, unequal. One case where it is of equal sign and in other case, it is of opposite sign. And here we have seen the case in which they are of the same sign, then origin is node and stable, unstable depending on the sign of the eigenvalue.

But in the other case, when  $\lambda_1$  and  $\lambda_2$  are unequal, real and are opposite sign,  $0, 0$  is

a saddle point. So here we will stop and we will continue in the next lecture. Thank you very much for listening. Thank you.
