Lecture – 25
Phase Portrait of Linear Differential Equations - II

Hello friends. Welcome to this lecture. So in this lecture, we will continue study of phase portrait of the linear system. So in previous lecture, we have discussed 2 case. In both the cases, we have assumed that eigenvalues are real, unequal and may be of same sign or of say opposite sign. So in this case, we will just continue our study. So in this, let us start with the third case. The third case is that roots are real but equal. So roots are real and equal.

(Refer Slide Time: 01:07)

Theorem-3

Real, unequal, same sign (node)

Theorem If the roots of the characteristic equation of the system (1) are real and equal, then the steady state is a node.

Proof: Let $\lambda_1 = \lambda_2 = \lambda < 0$. Here two cases arise.

Case (a): $a = d \neq 0, b = c = 0$

Case (b): else.

Proof of case (a): In this case $\lambda = a = d$ and therefore the system (1) reduces to

$$\begin{cases} \frac{dx}{dt} = \lambda x \\ \frac{dy}{dt} = \lambda y \end{cases}$$

*$\lambda = \lambda_1 = \lambda_2 = a = d$
 (u_1, u_2)*

$$\begin{pmatrix} x \\ y \end{pmatrix} = c_1 e^{\lambda t} \begin{pmatrix} u_1 \\ u_2 \end{pmatrix} + c_2 e^{\lambda t} \begin{pmatrix} v_1 \\ v_2 \end{pmatrix}$$

$\begin{pmatrix} x \\ y \end{pmatrix} = c_1 e^{\lambda t} \begin{pmatrix} u_1 + u_2 \\ v_1 + v_2 \end{pmatrix}$

18

So now in that case, let us have the following theorem. It says that if the roots of the characteristic equation of the system 1 are real and equal, then the steady state is again a node. So here this thing we have already, so in the case when it is real, unequal and of the same sign, then also it is node. And now in this case when we have real but it is not unequal, it is equal, then also it is a node.

So let us see that how it is? So let us say that consider λ_1 and $\lambda_2 = \lambda_1$ and let us assume that it is less than 0. So here we have 2 cases depending on a, b, c, d. So first case is that $a=d$ is non-0 and $b=c=0$. Basically, it is corresponding to the case then we have a scalar matrix

here. So it is a and d, diagonal matrix basically, right. Now in fact, in this case, $a=d$, so we can say that we have a scalar matrix.

And the other case when it is not a scalar matrix. So let us do proof one by one. So let us consider the case 1. In this case, we assume that $\lambda_1=\lambda_2$ and matrix is of this kind. So in this case, your λ is nothing but your, the value of a and d. So $\lambda=a=d$ here. So we can write down that system is $dx/dt=\lambda x$ and $dy/dt=\lambda y$. So in this case if you recall, your $\lambda_1=\lambda_2$ and equal to, let us say, this quantity, one of this quantity a or d.

So in this case when it is a scalar matrix, then this case we are assuming that since it is scalar matrix, your u and v are 2 linearly independent axis because it is a diagonalizable matrix. So it means that in this case, we must have 2 linearly independent eigenvector corresponding to $\lambda_1-\lambda_2=\lambda$. Let us call this value as λ . So in this case, your system is reduced to this $dx/dt=\lambda x$, $dy/dt=\lambda y$ and corresponding to λ , we have 2 linearly independent eigenvector u and v here.

(Refer Slide Time: 03:46)

The general system is, then,

$$\begin{aligned} x &= c_1 e^{(\lambda t)}, \\ y &= c_2 e^{(\lambda t)} \end{aligned}$$

where c_1 and c_2 are arbitrary constants.
 This solution represents half lines of all possible slopes. All these paths approach and enter $(0, 0)$ as $t \rightarrow +\infty$ because $\lambda < 0$. Thus the zero solution is a node and asymptotically stable.

Remark 1
 If $\lambda > 0$, then these paths enter $(0, 0)$ as $t \rightarrow -\infty$. Thus the zero solution is a node and unstable.
 This type of node is called a star-shaped node.

Handwritten notes on the slide:
 $\lambda < 0$
 $\begin{pmatrix} x \\ y \end{pmatrix} = e^{(\lambda t)} \begin{pmatrix} c_1 \\ c_2 \end{pmatrix}$
 A phase portrait diagram showing trajectories in the xy-plane for $\lambda < 0$. All trajectories are straight lines passing through the origin, with arrows pointing towards the origin, indicating a stable node.

Because we are assuming that linear system is, since matrix a is diagonalizable matrix because it is a scalar matrix. Basically, it is a diagonalizable matrix. So the general system will be solution is then $x, y=c_1 e$ to the power $\lambda r t$ and $c_2 e$ to the power λt , where c_1 and c_2 are arbitrary constants. In fact, you can look at here, solution will be what? $x, y=c_1 e$ to the power

$\lambda t u^1 u^2 + c_2 e^{\lambda t}$ to the power $\lambda t v^1$ and v^2 .

So if you look at here, what I can write it here? $x, y =$, now I can write it here, e to the power λt , you can take it out. Then it is what? $c_1 u^1 + c_2 v^1$ and $c_1 u^2 + c_2 v^2$, right. And these are some, since c_1 and c_2 are arbitrary, so it will take arbitrary values. So we can write down this solution as $x, y =$, so e to the power λt and here we have some constant c_1 and c_2 here. So $c_1 \sim$ or you can call it, these are some arbitrary constants c_1 .

Since c_1 and c_2 are arbitrary constants, so this $c_1 \sim$ and $c_2 \sim$ are also arbitrary. Let us call this as c_1 and c_2 here. So it means that here c_1 and c_2 are arbitrary constants. Now this solution represent half lines of all possible slopes. If you look at the slope of, this will be what? If you, just for the time being, let us forget this e to the power λt , then this will represent what? $x, y = c_1 \sim c_2 \sim$ and $c_1 \sim$ and $c_2 \sim$ are arbitrary.

So it means that the slope of this will be $c_2 \sim / c_1 \sim$. Now these are arbitrary, so slopes are also arbitrary. So it means that this represent the half line with the slope $c_2 \sim / c_1 \sim$. Now these are arbitrary, so it means that I can draw several lines, several half lines passing through origin, right. And your solution is tending to 0 because λ is, we have assumed that $\lambda < 0$. So as t tends to infinity, solution will tend to 0 along the line with the slope $c_2 \sim / c_1 \sim$.

So it means that your solution will tend to 0 along these lines here, right. So it means that in this case, your origin is a node because all the lines are approaching 0, 0 as well as entering 0, 0 along these lines, okay. So here 0, 0 is node and it is a stable node. Basically it is asymptotically stable node. And in this case, we call that 0 solution is node and asymptotically stable and we also have a special name for these kind of phase portrait and we call this that this type of node is called a star shaped node because every solution is entering to 0, 0 along the half lines, right.

So solution will enter to origin along these half lines. Now c_1 and c_2 are arbitrary, so these half lines are arbitrary, infinitely many half lines are towards origin 0, 0 here, right. And if $\lambda > 0$, then these path enter 0, 0 as t tends to $-\infty$ or we can say that they move towards infinity as t tending to $+\infty$ along these half lines.

So in this case, your half line will remain the same. The only thing is that solution is now moving away from origin. And in this case, $(0, 0)$ is node but unstable node. And these kind of nodes are known as star shaped node. So there is a case when your matrix are having equal roots and basically diagonalizable, that is the case we have considered.

(Refer Slide Time: 08:04)

Example 3

Draw the phase portrait for the linear system

$$\begin{aligned} y_1' &= y_1 \\ y_2' &= y_2. \end{aligned} \quad (8)$$

Solution: The only critical point of the given linear system is origin as

$$\begin{vmatrix} 1 & 0 \\ 0 & 1 \end{vmatrix} = 1 \neq 0. \quad \checkmark \quad \begin{pmatrix} 1 \\ 0 \end{pmatrix} \quad \begin{pmatrix} 0 \\ 1 \end{pmatrix}$$

The characteristic equation is given by

$$\begin{vmatrix} 1 - \lambda & 0 \\ 0 & 1 - \lambda \end{vmatrix} = 0 \Rightarrow \lambda_1 = 1 \text{ and } \lambda_2 = 1.$$

Thus, both the eigen-values are real, equal and positive, the critical point $(0,0)$ of the given system is an unstable node.

20

Now look at example based on this. So draw the phase portrait of the linear system $y_1' = y_1$, $y_2' = y_2$. The only critical point of the given linear system is $(0, 0)$ because their determinant is coming out to be 1. So it is non-0. So $(0, 0)$ is the only critical point and we can find out the eigenvalue of this. In fact, it is an identity matrix, so eigenvalues are nothing but 1, 1. And you can check that eigenvectors are $\begin{pmatrix} 1 \\ 0 \end{pmatrix}$ and $\begin{pmatrix} 0 \\ 1 \end{pmatrix}$ corresponding to $\lambda_1 = \lambda_2 = 1$.

So here your eigenvalues are real, equal and positive. So critical point $(0, 0)$ is node and it is unstable. It that okay?

(Refer Slide Time: 08:58)

Now this case when matrix is not-diagonalizable, it means that we are not having enough number of linearly independent eigenvectors, then what to do? So in this case, $\lambda_1 = \lambda_2$. Let us assume that it is negative but we are not able to get your enough number of linearly independent eigenvectors. So in this case, your general solution is given by $x = c_1 A e^{\lambda t} + c_2 A_1 t + A_2 e^{\lambda t}$; $y = c_1 B e^{\lambda t} + c_2 B_1 t + B_2 e^{\lambda t}$.

So let me write down your solution will be what? x, y to the power λt , your $u + e$ to the power λt , let us call this c_1 and c_2 here. Here we have $I + A - \lambda I t$, and here we have say, v here. So if you simplify this, it is what? $c_1 e^{\lambda t}$, it is $u_1 u_2 + c_2 e^{\lambda t}$ to the power λt , you can take it out, is $\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} + t$, this sum matrix, something and t , and this is v_1 and v_2 .

So when you simplify, you will get this kind of form, right. So x, y is given by this. Now not only this, please observe that these AB 's are constants and c_1 and c_2 are arbitrary constants. And we have this thing, $B_1/A_1 = B/A$. So how we can get this? If you look at this, that basically if you recall how we are obtaining this v here? v is called as generalized eigenvector and we obtained this v as the solution of something that $(A - \lambda I)^2 v = 0$, but, yes, it is $(A - \lambda I)^2 v = 0$. But $(A - \lambda I)v$ is non-0, okay.

So we have obtained like this. So if you look at, I can write this as $(A - \lambda I)$ operating on $(A - \lambda I)v = 0$. So if you look at this $(A - \lambda I)v$, if you call this as w , then this w is an eigenvector corresponding to the λ . Now we already have that u is an eigenvector corresponding to λ . So it means that w must be written as some constant multiple of u . So it means that w if I am writing as, w is basically this $(A - \lambda I)u$, so w is basically, if I look at here, w is basically given as A_1 and B_1 .

So here it is w_1 , so it is w_1 . Now, sorry w here. Now u is basically your A and B . So if you look at, this w is a constant multiple of u . So it means that w is constant multiple of u . It means that this $A_1 = k \cdot A$ and $B_1 = k \cdot B$ here where k is some non-0. So it means that we can easily verified that $B_1/A_1 = B/A$ here. Now here again we have 2 possible cases. Let us say that choosing $c_2 = 0$

and $c_1=0$.

So if you choose $c_2=0$, then this part is gone and we have $x, y=c_1 A e^{\lambda t}$ to the power λ , $c_1 B e^{\lambda t}$ to the power λ . So corresponding to this, your solution will be $x, y=c_1 e^{\lambda t}$ to the power λ and here we have simply u that is A and B here, right. So here $A B$ is just a constant. So we can simply, this simply represents a line passing through origin with a slope B/A . So these are lines here. Now as λ is negative, so solution is tending to $0, 0$ here, right.

(Refer Slide Time: 14:13)

For any $c_1 > 0$, the solutions (10) represent a path consisting of half of the line $Bx = Ay$ of slope B/A and for any $c_1 < 0$, they represent a path consisting the other half of this line. Since $\lambda < 0$, both of these half line paths approach and enter $(0, 0)$ with slope B/A as $t \rightarrow +\infty$.

$\lim_{t \rightarrow \infty} \frac{y}{x} = \frac{B}{A}$

Now as for any $c_1 > 0$, the solution 10 represent a path consisting of half of the line $Bx=Ay$. This is the line $Bx=Ay$, of slope B, A and for any $c_1 < 0$, they represent the path consisting the other half of this line. Now since $\lambda < 0$, both of these half line paths approach and enter $0, 0$ with the slope B/A as t tending to infinity. That we have pointed out here that this is the line having slope B/A and since λ is negative, so as t tending to infinity, x, y both are tending to $0, 0$ along the line having the slope B/A , okay.

(Refer Slide Time: 14:54)

If $c_2 \neq 0$, the general solution represents non rectilinear paths. These rectilinear paths also approach and enter $(0, 0)$ as $t \rightarrow +\infty$ with the same limiting slope. Thus all the paths (both rectilinear and non-rectilinear) enter $(0, 0)$ $t \rightarrow +\infty$ with slope B/A . Hence the critical point origin is a node and asymptotically stable.

Remark 2

If $\lambda > 0$, the same result will be obtained except that the fixed point is unstable in this case.

Now what happen if c_2 is non-0? So in this case, the general solution represent non-rectilinear paths. And these rectilinear paths also approach and enter $0, 0$ as t tending to $+\infty$ and with the same limiting slope. Just look at here, the solution is this. And so let us look at the slope here. So slope will be what? y/x . So y/x will be what? e to the power λt , you can take it out. So we will get $c_1 B + c_2$ and here we have $B_1 t + B_2$, and here we have $c_1 A + c_2 A_1 t + A_2$.

Now and if we divide it by t here, right, so what you will get? So I will get here $c_1 B/t$, here $c_1 A/t$, $+c_2 B_2/t$, here also $c_2 A_2/t$, $+c_2 B_1$ and here it is $c_2 A_1$. So these term will simply vanish. The only thing will left is, that B_1/A_1 . So limit of, so you get limit t tending to infinity $y/x = B_1/A_1$. So it is B_1/A_1 which is same as writing B/A here, right. So it means that the earlier line along with your solution is tending to origin, so it means that this says that even with non-rectilinear path also entering $0, 0$ along the same line which we have just drawn.

So it means that ultimately your solution are moving towards origin along the line this. Is that okay? So here, in this case, your all the solutions are entering $0, 0$ along the line given by this which is the line containing the eigenvector corresponding to the $\lambda_1 = \lambda$ here. So it means that here we have only 1 eigenvector and solution will tend to $0, 0$ along the half line given by this eigenvector here.

So in this case, all the paths, both rectilinear and non-rectilinear, enter $0, 0$ as t tending to

+infinity with slope B, A and hence the critical point origin is node and asymptotically stable. Now the other case when lambda is positive, that the same result will be obtained except that the fixed point is unstable in this case. So in this case, your fixed point is unstable.

(Refer Slide Time: 18:06)

So just for say phase portrait of this, let us consider the following thing. you have x, y dash = $1 \ 1 \ 0$ $1 \ x \ y$. So here eigenvalues $\lambda_1 = \lambda_2 = 1$, let us, okay. So here eigenvalues are same. Now corresponding to eigenvector, if you find out the eigenvector, eigenvector corresponding to $\lambda_1 = \lambda_2 = \lambda = 1$, it is $0 \ 1 \ 0 \ 0$. So and v_1 and v_2 . So solution will be that $v_2 = 0$. So your solution, eigenvector will get only this $1, 0$.

So there is no other linearly independent eigenvector available. So in this case, you have to find out the other eigenvector, means generalized eigenvector which is a solution of $(A - \lambda I)^2 u = 0$. So if you look at $(A - \lambda I)$, λ is 1 here, so it is $0 \ 1 \ 0 \ 0$ whole square, it means $0 \ 1 \ 0 \ 0$ and $u = 0$. So it is nothing but 0 matrix, u_1 and u_2 . So you can say that your, this will give you what?

This will give you that u_1 and u_2 may be any of choice. So we will choose the eigenvector which is linearly independent to the earlier ones. So it is let us say that $0, 1$ is your generalized eigenvector. So solution will be written as $x, y = c_1 e^{t} + c_2 e^{t} (1, 0)^T + c_2 t e^{t} (0, 1)^T$, and here we have I that is $1 \ 0 \ 0 \ 1$, $+t^*$, $(A - \lambda I)$ that is $0 \ 1 \ 0 \ 0$, and here

it is 0 1.

So you simplify $c_1 e^{(\alpha + i\beta)t} + c_2 e^{(\alpha - i\beta)t}$, $e^{\alpha t}$ to the power t you can still write and if you multiply, you will get $0 \ 1$ and here if you multiply, you will get $1 \ 0$ and t , right. So here it is if you recall this case, here. So here if you look at, A and B will be what? So here you can say we want to verify this $B_1/A_1 = B/A$, so that we can verify here. So this is A and B and this is your $A_1 B_1$, sorry, what is this?

It is $A_1 B_1$, okay. So it is $A_1 B_1$ and this is $A_2 B_2$. No A_1 corresponding to t , so here this is $A_2 B_2$ and this is $A_1 B_1$, because it is corresponding to. So we can easily see that here A and B and $A_1 B_1$ are same, exactly same. So of course ratio will be same, slope will be same. B_1/A_1 is same as B/A here. Is that okay?

So in this case, it is 0. So in fact, these are coming out to be same here, okay. So all the solution in this case will, so eigenvector is $1 \ 0$. So $1 \ 0$ means, 1 and 0. So $1 \ 0$ is a point here, $x=1$ and $y=0$, so it means that all these are, solution will tend to 0 and any other will tend towards 0. So your phase portrait will be like this, okay.

(Refer Slide Time: 21:43)

Theorem-4

Theorem If the roots of the characteristic equation of the system (1) are conjugate complex with nonzero real part, then the fixed point is a spiral point.

Proof: Let λ_1 and λ_2 be respectively $\alpha + i\beta$ and $\alpha - i\beta$ with $\alpha, \beta \neq 0$. Then the general solution of the system (1) may be written as

$$\begin{aligned} x &= e^{\alpha t} [c_1 (A_1 \cos(\beta t) - A_2 \sin(\beta t)) + c_2 (A_2 \cos(\beta t) + A_1 \sin(\beta t))] \\ y &= e^{\alpha t} [c_1 (B_1 \cos(\beta t) - B_2 \sin(\beta t)) + c_2 (B_2 \cos(\beta t) + B_1 \sin(\beta t))] \end{aligned} \quad (11)$$

where A 's and B 's are definite constants, c_1 and c_2 are arbitrary constants.

$\begin{pmatrix} x \\ y \end{pmatrix} = e^{(\alpha + i\beta)t} \begin{pmatrix} u_1 + i u_2 \\ v_1 + i v_2 \end{pmatrix}$

25

So now consider the next case, theorem 4. And it is corresponding the case when eigenvalues are complex and it is not purely imaginary. So it means that if the roots of the characteristic equation

of the system 1 are conjugate complex with non-0 real part, then the fixed point is a spiral point. So let us have the proof of this. So let lambda 1 and lambda 2 be given by alpha+i beta and alpha-i beta and none of them is 0.

So since we are assuming that it is complex, so beta is non-0 and we are also assuming that it has non-0 real part. It means that alpha is also non-0. Then the general solution of the system 1 may be written as this. $x=e$ to the power alpha t and so on, this one. So here how we can obtain this? If you recall, your solution will be what? $x, y=e$ to the power alpha+i beta t and $u_1+i u_2$, right and when you simplify, you will get this, right.

So it means that, this I am leaving it to you that please verify that your solution is given by equation number 11 here. So here Ai's and Bi's are different, definite constants and c1 and c2 are arbitrary constants. So definite constants means your A1 B1 is coming from this and another A1 B2 is given by this.

(Refer Slide Time: 23:16)

Let $\alpha < 0$, then from (11) we see that solution tends to origin as $t \rightarrow +\infty$. Also, we may rewrite (11) in the form

$$\begin{aligned} x &= e^{\alpha t}(c_3 \cos(\beta t) + c_4 \sin(\beta t)) \\ y &= e^{\alpha t}(c_5 \cos(\beta t) + c_6 \sin(\beta t)) \end{aligned} \quad (12)$$

where $c_3 = c_1 A_1 + c_2 A_2$, $c_4 = c_2 A_1 - c_1 A_2$, $c_5 = c_1 B_1 + c_2 B_2$, $c_6 = c_2 B_1 - c_1 B_2$. Assuming c_1 and c_2 are real, the above solution represent all paths in the real x-y phase plane. These solutions may be put in the form

$$\begin{aligned} x &= K_1 e^{\alpha t} \cos(\beta t + \phi_1) \\ y &= K_2 e^{\alpha t} \cos(\beta t + \phi_2) \end{aligned} \quad (13)$$

where $K_1 = \sqrt{c_3^2 + c_4^2}$ and $K_2 = \sqrt{c_5^2 + c_6^2}$ and ϕ_1 and ϕ_2 are defined by the equations

NPTEL ONLINE CERTIFICATION COURSE 26

So it means that let $\alpha < 0$. Now let us assume that since alpha is non-0, so it may be positive, it may be negative. So let us consider that $\alpha < 0$. So let $\alpha < 0$, then from 11, we see that the solution tends to origin as t tending to infinity. So as alpha is negative, t tending to infinity means this term is tending to 0, similarly this term also. So x, y is tending to 0, 0 as t tending to infinity.

Now we can rewrite our solution x and y in this following format. x, y as e to the power alpha t c3cos of beta t+c4sin of beta t and y as e to the power alpha t c5cos of beta t+c6sin of beta t. And where c3, c4, c5, c6 can be given as the earlier c1, c2, and A1 A2 B1 B2, we can write it like that. This is not very difficult. You rearrange and you simply arrange the coefficient of cos of beta t and sin of beta t, you will get this.

Now again we can rewrite this in a very compact form and it is given by this, x=k1e to the power alpha t cos of beta t+phi 1 and y as k2e to the power alpha t cos of beta t+phi 2. Now here this is using geometric, here k1 is given by under root c3 square+c4 square and k2 is given by under root c5 square+c6 square.

(Refer Slide Time: 24:47)

Let us now consider

$$\frac{y}{x} = \frac{K_2 e^{\alpha t} \cos(\beta t + \phi_2)}{K_1 e^{\alpha t} \cos(\beta t + \phi_1)} \quad (14)$$

Assuming $K = \frac{K_2}{K_1}$ and $\phi_3 = \phi_1 - \phi_2$, this becomes

$$\begin{aligned} \frac{y}{x} &= \frac{K \cos(\beta t + \phi_1 - \phi_3)}{\cos(\beta t + \phi_1)} \\ &= K \frac{\cos(\beta t + \phi_1) \cos \phi_3 + \sin(\beta t + \phi_1) \sin \phi_3}{\cos(\beta t + \phi_1)} \\ &= K [\cos \phi_3 + \sin \phi_3 \tan(\beta t + \phi_1)] \end{aligned} \quad (15)$$

And phi 1 and phi 2 are defined by the equation, this that cos of phi 1 is c3/k1, cos of phi 2=c5/k2, sin of phi 1=-c4/k1 and so on. So it means that, I am assuming that you can rewrite equation number 11 as equation number 13 here. So this is the more compact form and we start working with this. Now idea is to say that here since t tending to infinity, your x and y, both component will tend to, will approach to 0, 0.

Now we want to know that what is the limiting slope. If limiting slope is finite, we call that origin as node. If they are approaching but not entering 0, 0, then the origin is known as the spiral point or focal point. So here let us find out the slope here. Slope is y/x=k2e to the power

$\alpha t \cos(\beta t + \phi_2) k_1 e^{\alpha t} \cos(\beta t + \phi_1)$. Now in this ϕ_2 and ϕ_1 , since if c_1 and c_2 are arbitrary, then this ϕ_2 and ϕ_1 may not be the same thing.

So here by simple rearrangement, let us assume that $k = k_2/k_1$ and ϕ_3 as $\phi_1 - \phi_2$. And assuming that ϕ_1 and ϕ_2 , since c_1 and c_2 are arbitrary, so ϕ_3 is not ideally equal to 0 here. So y/x , we can rewrite like this. So $k \cos(\beta t + \phi_2)$ I am replacing as $\phi_1 - \phi_3$, so we are writing. And $\cos(\beta t + \phi_1)$. Now here we can simply simplify this using this as $A -$, so $\cos(A - B)$ you can apply and it is written as $k \cos(\beta t + \phi_1) \cos(\phi_3) + \sin$ of this thing/this.

Or we can rewrite this thing. The idea is that if take the limit here, then this is independent of t , this is independent of t , this will depend on t . So as t tending to infinity, $\tan(\beta t + \phi_1)$ will tend to infinity. So it means that limit does not exist, right. So we simply say that limit t tending to infinity, y/x is not a finite quantity. So it means that in this case, origin is not a node here. So though we know that $0, 0$ is stable but not a node.

And you can understand why we are doing all this thing. We can do it here also, but the thing is that here we simply say that here, these will cancel out. So k_2/k_1 , this may be equal if ϕ_2 and ϕ_1 are equal. So here you simply say that limit t tending to infinity, limit does not exist. That is why we did these kind of say arrangement.

(Refer Slide Time: 27:38)

Now since the limit of $\frac{y}{x}$ does not exist as $t \rightarrow +\infty$, the paths do not enter $(0, 0)$. But it follows from (14) and (15) that the path approach origin in a spiral like manner winding origin an infinite number of times as $t \rightarrow +\infty$. Thus the critical point is a spiral point. Also, it is asymptotically stable as $\alpha < 0$.

Remark 3

If $\alpha > 0$, the same situation arise except that origin is unstable in this case.

So here what we have concluded here? Now since the limit of y/x does not exist as t tending to infinity, the paths do not enter $0, 0$ but it follows from the previous equation that the path approaches origin in a spiral like manner. So it means that it is tending to $0, 0$ but it is not taking any say slope. So it means that there is no finite slope. So it means that there is a possibility that it will approach to origin in a spiral like manner, winding origin in an infinite number of times as t tending to infinity.

Thus the critical point is a spiral point. And also it is asymptotically stable as $\alpha < 0$. And if $\alpha > 0$, then situation will reverse. It means that it will be spiral but not a stable one. It will be unstable spiral. And here we simply say that origin is unstable spiral. Now here we can conclude the same thing from this. Here if you look at this, what you will get here? So we can write $x = k_1 e^{\alpha t} \cos(\beta t + \phi_1)$, $y = k_2 e^{\alpha t} \cos(\beta t + \phi_2)$.

So here we, in place of writing \cos of $\beta t + \phi_1$, we can again simplify and from here also we can get that it is basically kind of a periodic if you look at here, it is periodic of $2\pi/\beta$, right. So x is periodic with period $2\pi/\beta$ and y is also periodic with period $2\pi/\beta$ here. Is that okay? So here if I replace t by $t + 2\pi/\beta$. So what you will get? You will get x of $t + 2\pi/\beta$ will be $k_1 e^{\alpha(t + 2\pi/\beta)} \cos(\beta(t + 2\pi/\beta) + \phi_1)$ and y will be $k_2 e^{\alpha(t + 2\pi/\beta)} \cos(\beta(t + 2\pi/\beta) + \phi_2)$.

So βt will be βt and here β will be cancelled. It is 2π . So $\beta t + \phi_1 + 2\pi$. So it is

nothing but same. So it means that it will be coming out to the same thing. The only thing is that now radius is changed. It is not e to the power αt anymore. Now it is e to the power α , so it will be like, I can write it x of $t+2\pi/\beta = x * e$ to the power $2\pi \alpha/\beta$, right. So here we have assumed that α is negative.

And let us say that β is something. So here we can say that here your ray is changing, right. So here we simply say that I am assuming that now that β is positive here. So we simply say that the distance is reduced from the earlier one, right. So here we simply say that it is tending to 0, 0 with say radius lesser than the earlier one. So it means that it is basically, it is something like this, oh, sorry, just opposite, or this way.

So again there are 2 possibilities. Whether it will follow this or it will follow this. It depends on, I think it is same, sorry, it is like this. So it is the, this thing side, okay. So here there are 2 possibilities.

Example 4

Draw the phase portrait for the linear system

$$\begin{aligned} y_1' &= y_1 - y_2 \\ y_2' &= -y_1 + y_2 \end{aligned} \quad (16)$$

Solution: Origin is the only critical point of the given linear system as

$$\begin{vmatrix} 1 & 1 \\ -1 & 1 \end{vmatrix} = 2 \neq 0.$$

The characteristic equation of the given differential equation is given by

$$\begin{vmatrix} 1-\lambda & 1 \\ -1 & 1-\lambda \end{vmatrix} = 0 \Rightarrow \lambda_1 = 1+i \text{ and } \lambda_2 = 1-i.$$

Since, both the eigen-values are complex conjugates with positive real part, the critical point $(0,0)$ of the given system is an unstable spiral point.

Now let us consider one example. So it will follow which path, that will depend on the equation itself. Now let us look at this example, example 4. Draw the phase portrait for the linear system $y_1 \text{ dash} = y_1 + y_2$, $y_2 \text{ dash} = -y_1 + y_2$ and we want to look at the behaviour of origin that is 0, 0. And we can check that origin is the only critical point of the given linear system that is because determinant is non-0.

And look at the eigenvalues here. So eigenvalues is coming out to be $\lambda_1 = 1+i$ and $\lambda_2 = 1-i$. So eigenvalues are complex conjugate to each other with positive real part. So in this case, $(0, 0)$ is the spiral point but it is unstable spiral point. And we want to find out the phase portrait in this case. So here there are 2 possibilities that the solution will move like this or solution will move.

So which one it will follow? Whether it is going the anticlockwise or it is moving the clockwise. It is anticlockwise here. So which path it will follow? So for that, choose a point on, let us say choose this point, right. Similarly, here. So let us say this is y_1 here and this is y_2 here. This is y_1 here and y_2 here. So at this particular point, your y_2 is 0 and y_1 is positive. And here if you look at above this, y_2 is positive and below this, y_2 is negative.

So basically we want to look at the behaviour of y_2 at this particular point. So to look at the behaviour of y_2 , look at the second equation, differential equation in terms of y_2 . So here $\dot{y}_2 = -y_1 + y_2$. So at this particular point, your y_1 is positive. So this is negative. $y_2 = 0$, so this is simply, so at this point your $\dot{y}_2 = -y_1$. So y_1 is positive. So \dot{y}_2 is negative. So it means that y_2 is decreasing.

So it means that your y_2 is coming from positive to negative side because y_2 is 0 here and here it is decreasing. So it means that y_2 is going to negative side rather than positive side. So it means that it will follow this path only, rather than this path. Because here, at this particular point, your direction is this way. So here at this particular point, your y_2 is moving from negative side to positive side.

It means that here \dot{y}_2 has to be positive but from the equation, it is coming out that \dot{y}_2 is negative. So it means that this is not the correct phase portrait. This is the correct phase portrait, okay. So here we have seen that both the eigenvalues are complex conjugate with this positive real part, the critical point $(0, 0)$ of the given system is unstable spiral point here. So with this, we will finish our lecture here.

So in this lecture, what we have discussed 2 cases, one is when eigenvalues are real but equal. In that case, we have shown that origin is node but whether it is star shaped or say it is only simple a node, that will depend on the eigenvectors corresponding to the eigenvalues λ . And other case, we have considered is that when λ_1 and λ_2 are complex conjugate to each other and we have non-0 real part.

In this case, we have shown that it is a spiral point. Now whether it is stable or unstable, that will depend on the real part of the eigenvalue λ . So if real part of the eigenvalues are positive, then it is unstable. If real part of the eigenvalue is negative, then it is stable spiral point. So in next class, we will consider one more case and we will discuss some more properties. So with this, we will conclude and thank you very much for listening us. Thank you.
