Lecture – 29
Lyapunov Stability - I

Hello friends, welcome to this lecture, in this lecture we will discuss the Lyapunov stability of dynamical system in fact, we have already discussed some concept of stability in previous few lectures also but in this lecture, in all those lectures when we try to discuss the say, stability of linear system then it is a problem of finding the say, sign of real part of the eigenvalues of the linear matrix A but when we try to solve the; when we try to find out the stability of non-linear system, then we consider the corresponding linear system.

And then we try to find out the this similar thing which we have solve which we have done for linear system, so in all those cases, we basically try to find out some solution and then we do all this thing but in case of Lyapunov stability, we need not to find out solutions of the dynamical system in fact, here we try to find out a function which is known as a Lyapunov function having certain properties, so here without solving without finding the solution of dynamical system, we can find out the stability behaviour of the dynamical system.

In fact, one more thing which we can obtain through the Lyapunov stability or with the help of Lyapunov function that here we can find out the region in which your dynamical system is stable, unstable or say asymptotically stable thing, so here the new thing is that we can find out the region in which your solution is stable here, so these things we can obtain with the help of Lyapunov function but the difficult part in case of Lyapunov function is to construct the Lyapunov function.

So, if you are a good enough to find out the Lyapunov functions, then we can achieve all these benefit here, so in fact there is no general method to find out the Lyapunov function for given dynamical system, so all this thing we try to discuss in this and the next lecture so, let us first start the Lyapunov stability of a non-linear system.

Lyapunov stability of autonomous system

Consider an autonomous system

$$\dot{x} = f(x) \quad (1)$$

where $f \in C[\mathbb{R}^n; \mathbb{R}^n]$.

Assume that f is smooth enough to ensure the existence and uniqueness of the solutions of (1). Let Ω be an open set in \mathbb{R}^n containing the origin.

So, first consider an autonomous system $\dot{x} = f(x)$, here f is a continuous function from \mathbb{R}^n to \mathbb{R}^n , so it is basically $n \times 1$ system, x is a $n \times 1$ vector and assume that f is smooth enough to ensure the existence and uniqueness of the solutions of (1), so it means that here we are assuming that dynamical system is having solutions and solutions are satisfying the uniqueness conditions also.

So, let Ω be an open set in \mathbb{R}^n containing the origin here, so now the function; Lyapunov function V which we are talking about, it satisfy certain properties, let us do some basic concept and try to identify those properties, so first let us define certain things so, suppose $V(x)$ is a scalar continuous function defined in Ω , so Ω is already defined, Ω is an open set in \mathbb{R}^n which contains the origin.

(Refer Slide Time: 04:13)

Suppose $V(x)$ is a scalar continuous function defined on Ω . Then

- 1 A scalar function $V(x)$ is said to be positive definite on the set Ω if and only if $V(0) = 0$ and $V(x) > 0, \forall x \neq 0$ and $x \in \Omega$.
- 2 A scalar function $V(x)$ is said to be positive semi-definite on the set Ω when V has the positive sign throughout Ω , except at certain points where it is zero.
- 3 A scalar function $V(x)$ is negative definite(negative semi-definite) on the set Ω if and only if $-V(x)$ is positive definite(positive semi-definite) on the set Ω .

$$\begin{array}{ll} V(x) \text{ PD} & -V(x) \text{ ND} \\ V(x) \text{ PSD} & -V(x) \text{ NSD} \end{array}$$

So, V is a scalar continuous function defined on Ω , then we a scalar function Vx is said to be a positive definite on the set Ω , if and only if $V(0) = 0$ at, it means that at origin, it is 0 and in all other point, it is positive, so Vx is positive for all x which are nonzero and x belongs to Ω , so it means that positive definite means that it can it is taking value at origin and in all other point, it is taking only the positive value.

So, in this case we say that Vx is a positive definite on the set Ω , where it satisfy this properties. Now, second is a scalar function Vx is said to be a positive semi-definite on the set Ω , when V has the positive sign throughout Ω except at certain points where it is 0, so it means that positive semi definite means it is taking only the nonnegative values, so it is taking either the value 0 or the positive value, right.

So, it means that there are certain points where it is 0, in all other points, it is taking only the positive value, so in that case we say that Vx is a positive semi definite on the set Ω similarly, we can define the negative definite, so a scalar function Vx , negative definite or negative semi definite on the set Ω if and only if $-Vx$ is positive definite, so it means that Vx is negative definite means that $-Vx$ is positive definite.

So, here we simply say Vx is negative definite, means $-Vx$ is positive definite, similarly Vx is negative semi definite means, $-Vx$ is positive semi definite here on the set Ω , so here Vx

is positive definite then - of Vx is negative definite and if Vx is positive semi definite, then - of Vx is negative semi definite here. So, in this way we can define the positive definite, positive semi definite, negative definite and negative semi definite.

(Refer Slide Time: 06:45)

Example 1

For $n=3$, consider the functions

- 1 $V_1(x) = x_1^2 + x_2^2 + x_3^2$ PD
- 2 $V_2(x) = x_2^2$ PS
- 3 $V_3(x) = x_1^2 + (x_2 + x_3)^2$ PS

Here V_1 is positive definite but the function V_2 is not.

Handwritten notes:

- $x_1^2 + x_2^2 \leq \|x\|^2$
- $\|x\|^2 = x_1^2 + x_2^2$
- $x_1^2 + x_2^2 = (x_1^2 + x_2^2) - 2x_1^2 x_2^2 = \|x\|^2 - 2x_1^2 x_2^2$
- $V_2(x) = 0 \quad (x_1, 0, x_3)$
- $V_2(x) \geq 0$
- $V_2(x) = 0 \Rightarrow x_2^2 = 0 \Rightarrow x_2 = 0$
- $V_1(x) = 0 \Rightarrow x_1^2 + x_2^2 + x_3^2 = 0 \Rightarrow (x_1, x_2, x_3) = (0, 0, 0)$
- $x_1 = 0, \quad x_2 + x_3 = 0, \quad x_2 = -x_3$
- $V_4(x) = x_1^2 + x_2^2 - x_1^4 - x_2^4 = \|x\|^2 - x_1^4 - x_2^4, \quad n=2, \quad x = \begin{pmatrix} x_1 \\ x_2 \end{pmatrix}$

So, let us take some example to identify this, so first let us say for $n = 3$, now consider some functions, so here first function is $V_1x = x_1^2 + x_2^2 + x_3^2$, so since it is sum of squares so, it will always take the value 0 or say, nonzero, positive values, so if you look at when it will take the value 0, so $V_1 x = 0$, implies that $x_1^2 + x_2^2 + x_3^2 = 0$, so it means that this is possible only when x_1 , and x_2 and x_3 are all 0.

So, it means that it is taking value only a 0, only on the; only at the origin and in all other point this is basically, positive value, it is sum of positive values, so it is taking the positive value, so it means that it is taking 0 value only at the origin and in all other point where x is nonzero, it is taking the positive value, so V_1x is your positive definite scalar function now, similarly we can define $V_2x = x_2^2$ square.

Now, here again we can say that since it is V_2x is given as a square of some x_2 , so it means that V_2x will take only say nonnegative value and if you look at if you put $V_2x = 0$, then this implies that your $x_2^2 = 0$, so this implies that $x_2 = 0$ but it gives no condition on the other

component x_1 and x_3 , so it means that that V_2x will be 0 provided we have all this kind of a structure here.

So, x_1 , x_2 and $x_1 \neq 0$ here, so it means that on x_1 x_3 plane, where $x_2 = 0$, V_2x may take the zero value, so it means that it is taking positive value, nonnegative value throughout the domain and it is taking 0 value other than origin also, so in this case V_2x is a positive semi definite function, so here it is PD positive definite, it is positive semi different here, so it is taking only the nonnegative value here.

So and it is a taking value 0 other than origin also, so it is a positive semi definite function, now defined $V_3x = x_1^2 + x_2 + x_3$ whole square, again it is given as some of the squares function, so it is basically taking nonnegative value. Now, we need to find out that at what point it is taking the value 0, so here it is taking the value 0 provided that $x_1 = 0$ and $x_2 + x_3 = 0$, so here this may gives you the entire plane.

So, we can say that $x_2 = -x_3$, so it is, it may take value other than origin, so it means that here it is taking nonnegative value and it may take value zero other than origin also, so in this case your V_3 function is again a positive semi definite function. Similarly, we can define one more function say V_4x as $x_1^2 + x_2^2 - x_1^4 - x_2^4$, here let us take $n = 2$ here, so it means that we have only x as x_1 and x_2 here, right.

So, if we look at this V_4x square, now it is quite difficult to find out whether it is taking all the positive value or negative value, so here if you look at $x_1^2 + x_2^2$, I can write this as norm of x whole square $- x_1^4 - x_2^4$ here, now here we know that norm of x square is basically $x_1^2 + x_2^2$, now what about this $x_1^4 + x_2^4$, if we add, so this I can write as $x_1^2 + x_2^2$ whole square of this $- 2x_1^2$ and x_2^2 square, right.

So, - of this will be; so I can write this as this is what; this is norm of x to the power 4, -2 of $x_1^2 - x_2^2$, this $-x_1^2 - x_2^2$, so here these 2 are minus, okay, so this implies this, so here if you look at $x_1^4 + x_2^4$ is some values which is $< x_2^4$

here, so I can write that x_1 to the power 4 + x_2 to the power 4 is something which is less than so, is $> =$; sorry, this is x to power 4 here.

So, it means that here we are subtracting some positive value, some nonnegative value to get x_1 to the power 4 + x_2 to the power 4, so it means that x_1 to the power 4 + x_2 to the power 4 is $<$ norm of x to the power, so - of x_1 to the power 4 - x_2 to the power 4 is $> =$ norm of x_2 to the power 4 here, so I can write this as this is $> =$; so here we can say that x_1 to the power + x_2 to the power 4 is written as norm of x_2 to the power 4 - $2x_1$ square + x_2 square.

So, if we use the value x_1 to the power 4 + x_2 to the power 4 as this, then we can write V_4x as norm of x square -; in place of x_1 to power 4 - x_2 to power 4, we are writing $-x_2$ to power; norm of x_2 to power 4 + $2x_1$ square x_2 square.

(Refer Slide Time: 12:58)

Handwritten mathematical derivation:

$$V_4(x) = \|x\|^2 - \|x\|^4 + 2x_1^2 x_2^2$$

$$= \|x\|^2 (1 - \|x\|^2) + 2x_1^2 x_2^2$$

Condition: $0 < \|x\| < 1$

$V_4(x) > 0$

$V_4(x) = 0 \Rightarrow \|x\|^2 - \|x\|^4 + 2x_1^2 x_2^2 = 0$

$(0, 0)$

$$\|x\|^2 (1 - \|x\|^2) = 0$$

$$\|x\|^2 x_2^2 = 0$$

$\|x\|^2 = 0 \Rightarrow x_1 = 0 \text{ or } x_2 = 0$

$\|x\|^2 = 0 \Rightarrow x_1 = 0 \text{ \& } x_2 = 0$

So, we can let us use this here, so V_4x we have written as norm of x square - norm of x to power 4 + 2 times x_1 square x_2 square, now we simply take the first 2 term, we can take that norm of x square $1 -$ norm of x square + 2 times x_1 square x square, so now if we define a domain like this that if norm of x is < 1 and > 0 , then it will take this value is positive, this value will also be positive because norm of x is < 1 and this is also positive here.

So, it means that in this range, your V_4x is all the time positive here and if V_4x is 0 implies what; that norm of x square - norm of x_2 to the power 4 +2 times x_1 square x_2 square, so here we can simply say that at 0, 0 it is taking value 0, so 0, 0 is certainly the point where V_4x is 0 and if we put this condition that norm of x is < 1 , then this is the only point where it is vanishing because in that case when norm of x is < 1 , then this is positive, this is positive, this is positive.

So, some of these square will be positive, it means that this can be make 0, this will be positive if x_1 square x_2 square is 0 and this term is also 0, so this is possible, this cannot be; okay, so let me write it here, if norm of x is < 1 , then this will be 0 provided norm of x square * 1 - norm of x square = 0 and here x_1 square x_2 square = 0, simultaneously, this implies that $x_1 = 0$ or $x_2 = 0$ here and this 0 implies this cannot be 0.

So, only possibility is that norm of x square = 0, so this implies that $x_1 = 0$ and $x_2 = 0$ here, so it means that if we restrict our domain as norm of $x < 1$, then V_4x will take the value 0, only at the origin and no other point, so it means that V_4x is a positive definite function in a domain, norm of $x < 1$, right and it is ≥ 0 , so in this, so in unit cycle, so in n the interior part of unit cycle, it is a positive definite scalar function, okay.

So, here we have defined this now, more, in general we can define the Lyapunov function as a quadratic form basically, so we will now discuss some concepts related to quadratic form, so let V of x is given as summation $i, j = 1$ to n , $B_{ij} x_i x_j$, here x_i and x_j are say component of x , so here it is x_1 to say x_n here, right.

(Refer Slide Time: 16:36)

Lyapunov stability of autonomous system

Let

$$V(x) = \sum_{i,j=1}^n b_{ij} x_i x_j \quad x = \begin{pmatrix} x_1 \\ \vdots \\ x_n \end{pmatrix}$$

be a quadratic form where $b_{ij} = b_{ji}$.

The derivative of V with respect to (1) is defined as the scalar product

$$V^*(x) = \text{grad}V(x) \cdot f(x) = \frac{\partial V}{\partial x_1} f_1(x) + \frac{\partial V}{\partial x_2} f_2(x) + \dots + \frac{\partial V}{\partial x_n} f_n(x)$$

$x' = f(x)$
 $x'_1 = f_1(x_1, \dots, x_n)$
 $x'_2 = f_2(x_1, \dots, x_n)$
 \vdots
 $x'_n = f_n(x_1, \dots, x_n)$

Thus if $x = x(t)$ is any solution of (1), then using chain rule, we obtain

$$\frac{d}{dt} V(x(t)) = \frac{\partial V}{\partial x_1} x'_1(t) + \frac{\partial V}{\partial x_2} x'_2(t) + \dots + \frac{\partial V}{\partial x_n} x'_n(t) = V^*(x(t))$$

$= \sum_{i=1}^n \frac{\partial V}{\partial x_i} f_i(x)$

So, with the help of x , we can define V_x as this, $i, j = 1$ to n $b_{ij} x_i x_j$ where $b_{ij} = b_{ji}$ and we call this as quadratic form, so now with the help of this quadratic form, let us find out the derivative here, we will see that how this calculation of derivative is quite important, so that derivative of V with respect to 1 means, $x \text{ dash} = f$ of x is defined as the scalar product, $V \text{ star } x = \text{grad of } V \text{ of } x \text{ dot } f \text{ of } x$.

So, grad of V of x will be $\text{doub } V / \text{doub } x_1, \text{doub } V / \text{doub } x_2$ and $\text{doub } V / \text{doub } x_n$ and then f of x means your f of x is basically f_1x, f_2x and so on, so when you take the vector product say dot product, then it is $\text{doub } V / \text{doub } x_1 * f_1x + \text{doub } V / \text{doub } x_2 f_2x + \text{so on } \text{doub } V / \text{doub } x_n f_nx$ here, so $V \text{ star } x$ we defined as $\text{grad } V_x \text{ dot } f \text{ of } x$ here and it is given by the expression given into. Now, if $x =; x_t$ is any solution of 1, means $x \text{ dash} = f$ of x .

Then we can; in fact, use same rule to obtain d/dt of V of $x t$, so here it is given as any x_1 to x_n , may not be the function of n here, so it may not give function of t , here, so now let us assume that x is a function of t and now find out d/dt of V of x_t , so this can be done by choosing the; while using the chain rule, so here V is the function of x and x is a function of t , so to find out d/dt of V of x_t , so here it is V is a function of say x_1 to say x_n .

And each one is a function of t , here, so we to find out dV/dt here, we simply say derivative of V with respect to x_1 and derivative of x_1 with respect to t , so $\text{doub } V / \text{doub } x_1$ and $dx_1/dt + \text{doub } V /$

$\frac{d}{dt} x_2$ and so on, so now if you look at here, if you look at the 1 here, so this I can write it as $\dot{x}_1 = f_1(x_1, x_2, \dots, x_n)$, $\dot{x}_2 = f_2(x_1, x_2, \dots, x_n)$ and so on $\dot{x}_n = f_n(x_1, x_2, \dots, x_n)$ here, so using the expression for \dot{x}_1 , I can write this as $\frac{dV}{dx_1}$, in place of \dot{x}_1 , we can write f_1 .

And $\frac{dV}{dx_2}$ in place of \dot{x}_2 we can write f_2 and so on, so if you look at this is nothing but $\frac{dV}{dx_1}$ and this is $f_1 + \frac{dV}{dx_2}$ is f_2 and so on $\frac{dV}{dx_n}$ f_n , so if we look at this is nothing but this expression given into, so we can write this as V^* of x of t , here, so by $\frac{d}{dt} V(x,t)$ is nothing but $V^*(x,t)$, so it means that this the derivative of V with respect to t which is a given as $V^*(x)$ is given by $\frac{d}{dt} V(x,t)$, when x is a function of t , here, right.

(Refer Slide Time: 20:11)

Example 2

Consider the system

$$\begin{aligned} \dot{x}_1 &= x_2, \\ \dot{x}_2 &= -x_1 - 2x_2. \end{aligned}$$

and the corresponding function $V(x_1, x_2) = \frac{1}{2}[x_1^2 + x_2^2]$.

$$\begin{aligned} V^* &= \text{grad } V \cdot f(x) \\ &= \frac{d}{dt} V(x(t)) \\ &= \frac{\partial V}{\partial x_1} \dot{x}_1 + \frac{\partial V}{\partial x_2} \dot{x}_2 \\ &= x_1 \dot{x}_1 + x_2 \dot{x}_2 \\ &= x_1(x_2) + x_2(-x_1 - 2x_2) \\ &= x_1 x_2 - x_2 x_1 - 2x_2^2 \\ V^* &= -2x_2^2 \end{aligned}$$

NPTEL ONLINE
CERTIFICATION COURSE

Now, let us consider the system $\dot{x}_1 = x_2$ and $\dot{x}_2 = -x_1 - 2x_2$, now here we try to find out the V^* here, so first look at let us say that $V(x_1, x_2)$ is $\frac{1}{2}(x_1^2 + x_2^2)$ and we want to find out V^* here, so V^* is basically what; V^* is nothing but $\text{grad } V \cdot f$ of x , right or we can say that it is nothing but $\frac{d}{dt} V(x,t)$, here, right so we will use this thing.

So, if we use this then it is what; it is $\frac{dV}{dx_1} \dot{x}_1 + \frac{dV}{dx_2} \dot{x}_2$, so what is $\frac{dV}{dx_1}$; so if you look at here we can find out $\frac{dV}{dx_n}$ is nothing but simply x_1 , it is 2 times x_1 and $\frac{1}{2}$ is already there, so we can simply say it is nothing but x_1 , so it is x_1

$\dot{x}_1 +$, similarly \dot{V} / \dot{x}_2 it is 2 times x_2 , 2 is can be cancelled out from this, so it is again x_2 and \dot{x}_2 here.

Now, we already know what is the expression for \dot{x}_1 and \dot{x}_2 , so we can write \dot{x}_1 is x_2 here + x_2 , \dot{x}_2 is $-x_1 - 2$ of x_2 here, so if you simplify x_1 , $x_2 - x_2 x_1 - 2$ of x_2 square so this will be cancel out and it is nothing but -2 of x_2 square, so V^* is given as $-$ of 2 of x_2 square here, so here this V^* is given as -2 of x_2 square, we can easily check that this is nothing but negative semi-definite function.

(Refer Slide Time: 22:12)

Theorem 3

If there exists a scalar function $V(y)$ that is positive definite and for which $V^*(y) \leq 0$ on some region Ω containing the origin, then the zero solution of $y' = f(y)$ is stable.

Proof: Since V is positive definite, there exists a sphere of radius $r > 0$, centered at origin, contained in Ω , such that

$$\checkmark V(y) > 0 (y \neq 0, \|y\| \leq r) \quad \text{and} \quad V^*(y) \leq 0 (\|y\| \leq r) \quad \checkmark$$

Let $y_0 \neq 0, \|y_0\| < r$ be given. Consider the solution $\phi(t)$ of $y' = f(y)$ with $\phi(0) = y_0$. By local existence, this solution exists on $0 \leq t < t_1$, for some $t_1 > 0$ and can be continued to the right for as long as $\|\phi(t)\| \leq r$.

Anyway, so now once we have something related to this function V , now let us consider the main theorems for finding the stability of given system, so one important theorem is given as theorem number 3 three. So, it says that if they exist a scalar function V of y that is positive definite and for which $V^* y \leq 0$ on some region Ω , which contains the origin then the zero solution of $\dot{y} = f(y)$ is stable.

So, here we are assuming that zero is a solution of $\dot{y} = f(y)$ and we are able to find out a function V of y which is positive definite and $V^* y$ is negative semi-definite, in that case origin which is zero solution is a stable solution, so basically it is what; we are able to find out a positive definite function whose derivative is negative semi-definite, then we are saying that $\dot{y} = f(y)$ has a zero solution which is a stable solution, okay.

So, since V is positive definite, then there exists a sphere of radius $r > 0$ centred at origin containing ω and such that that V of y is > 0 $y \neq 0$ and norm of y is $< r$, $< r = r$ and V star y is ≤ 0 norm of $y \leq r$, so here the first expression is given with the help of positive definiteness of V of y , so since V of y is positive definite, so it can take value 0 only at origin and in all other point, it is taking the positive value only.

So, V of y is positive when $y \neq 0$ and norm of y is $\leq r$, we are considering everything in the inside the sphere of radius $r > 0$ and it is already given that V star y is ≤ 0 on some region ω containing the origin, so this sphere is inside you know, ω , so this also be true that V star y is ≤ 0 norm of $y < r$. Now, let us take one initial point say y_0 which is nonzero and it is inside your ω , inside your sphere of radius r .

So, it means that norm of y_0 is $< r$ be given, now we find out one solution $\phi(t)$ of $y' = f$ of y with $\phi(0) = y_0$, so let us consider a solution of initial value problem that is $y' = f y$ with the condition that $\phi(0) = y_0$, so we; so here I am assuming that f is smooth enough, so it means that we assume that solution exists so, by local existence, this solution exist on some interval say, $0 \leq t \leq t_1$, for some $t_1 > 0$.

So, this is a standard existence theorem that if f is smooth enough, then this initial value problem has a solution in fact, if we take more smoothness on f , then we can have a unique solution here and this can be continued to the right of t, t_1 as long as that norm of $\phi(t)$ is $\leq r$, so we keep on applying the same result and we can say that the solution of $y' = f y$ with $\phi(0) = y_0$, can be continued, can be extended till the right of your t_1 also as well as t_1 also, only till your norm of $\phi(t)$ is $\leq r$.

(Refer Slide Time: 26:27)

Suppose that $[0, t_1)$ is the largest interval of existence of the solution $\phi(t)$ that can be achieved by continuation. Then either $t_1 = +\infty$ or $0 < t_1 < +\infty$. We will show that for small enough $\|y_0\|$, second case, i.e., $0 < t_1 < +\infty$ can not arise. Since

$$\frac{d}{dt} V(\phi(t)) = V^*(\phi(t)) \leq 0, \quad (0 \leq t < t_1)$$

integrating

$$V(\phi(t)) - V(y_0) = \int_0^t V^*(\phi(s)) ds \leq 0$$

Therefore,

$$0 < V(\phi(t)) \leq V(y_0) \quad (0 \leq t < t_1) \quad (4)$$

where the inequality follows from the assumption $y_0 \neq 0$.

$y' = f(t, y), \phi(0) = y_0$
 $\phi(t) \neq 0$

It means that $\phi(t)$ is inside the sphere of radius r , so suppose that 0 to t_1 is the largest interval of existence of the solution $\phi(t)$, so it means that by doing, by repeated application of existence theorems, suppose this is the interval 0 to t_1 is an interval where your solution exists, so $\phi(t)$ that can be achieved by the continuation. Then claim is that either t_1 is $< \infty$; $= \infty$ or t_1 is $< \infty$.

Now, we wanted to show that if norm of y_0 is small then and t_1 is $< \infty$, then we can get some contradictions, so it means that for small enough norm of y_0 , the second case that is t_1 is $< \infty$ is not possible, so idea is to show that if we start, if we take a solution inside the sphere or then it will remain all the time in the sphere of radius r only, so it means that when t_1 is tending to infinity, then also your solution is will remain inside the sphere of radius r .

So, it means that the possibility that t_1 is $< \infty$ may not arise, so t_1 has to be $= \infty$, so to show that this is true, we use this condition that $V^* \phi(t) \leq 0$ and we have already shown that $V^* \phi(t)$ is nothing but d/dt of V of $\phi(t)$ here, so through $t \leq t_1$, sorry $t \geq 0 < t_1$ d/dt of $V \phi(t) \leq 0$, this is already given that $V^* \phi(t)$ is negative, so we simply integrate with respect to t here, so we will get V of $\phi(t) - V$ of y_0 , from 0 to t $V^* \phi(s) ds$.

Now, $V^* \phi(s) \leq 0$, t is positive, so this will be ≤ 0 , so it means that your V of $\phi(t)$ is $\leq V$ of y_0 which we have achieved from this. Now, we already know that since y_0 is nonzero,

then $\phi(t)$ cannot be 0, why because if we have $\dot{y} = f(y)$ and initial condition is that your $\phi(0) = y_0$, now if y_0 is nonzero, then if y_0 is 0, then it will have only a unique solution that is zero solution.

But if y_0 is nonzero, then zero solution cannot be a solution of this and by existence and uniqueness theorem, if $\phi(t)$ is a solution of this initial value problem then $\phi(t)$ is cannot be equal to a zero solution, so it means that $\phi(t)$ is not a 0, so it means that V of $\phi(t)$ has to be > 0 because V is positive definite, so it means that with the condition that $V^* \phi(t)$ is non-positive and V is a negative definite, we have obtained that $0 < V \phi(t) \leq V y_0$, for all $t < t_1$ here.

So that is the inequality given in equation number 4, so where the inequality follows from the assumptions at $y_0 \neq 0$, so this inequality is followed from the assumption that y_0 is nonzero, so it means that 0 is not a solution of this and hence $\phi(t)$ is all the time positive, nonzero.

(Refer Slide Time: 30:03)

Let $\epsilon > 0$ be given with $0 < \epsilon \leq r$ and let $S = \{y \mid \epsilon \leq \|y\| \leq r\}$. Then by continuity of V and the fact that S is closed, $\mu = \min_{y \in S} V(y)$ exists and is strictly positive. Since $\lim_{y \rightarrow 0} V(y) = 0$, we can choose a number δ , $0 < \delta < \mu$ such that for $\|y_0\| \leq \delta$, $V(y_0) < \mu$. Then according to (4), the solution $\phi(t)$, $\phi(0) = y_0$, $\|y_0\| \leq \delta$ satisfies

$$0 < V(\phi(t)) \leq V(y_0) < \mu \quad \text{for } (0 \leq t < t_1) \quad (5)$$

But as $\mu = \min_{y \in S} V(y)$ this implies that $\|\phi(t)\| < \epsilon$ for $0 \leq t < t_1$. This implies that $t_1 = +\infty$ because if at some first point $t_2 > t_0$, $\|\phi(t_2)\| = \epsilon$, then for $t = t_2$, we also have, from the definition of μ and from (5)

$$\mu \leq V(\phi(t_2)) \leq V(y_0) < \mu$$

which is absurd.

So, let $\epsilon > 0$ be given with $0 < \epsilon \leq r$ and let $S =$ all those y such that norm of y is $< = r$ and $> = \epsilon$ now, what we try to prove now that if this 4 is true then your solution will remain very small if we take y_0 , norm of y_0 very small, so that is what we want to show that we can, we want to find out for every ϵ , they exist a $\delta > 0$, they exist a $\delta > 0$ such that norm of this $\phi(t)$ is $< \epsilon$, whenever norm of y_0 is $< \delta$.

So, we want to show this thing, so let us say that corresponding to this epsilon, you define a domain like S , so let $S =$ all those y whose norm is lying between epsilon and r , right and we assume that this then by basically, it is this, so it is epsilon and it is; so this is the reason which is given by this is, right so it means that S is close because it contains the bounded point also, so S is close and V is continuous.

So, we can use the (31:42) theorem and we can say that continuous function define on a closed region will attain the maximum and minimum value inside your close region here, so let us say that μ which we define as the minimum of V of y were y is running over this S , so it means that μ exist and it is strictly positive, why so, why because norm of y is $\geq \epsilon$ and ϵ is positive right.

So, it means that V_y take only positive value in this region S , right and it will not take any negative value, so here we simply say that V_y is strictly positive, it can take only value 0, when your y is 0, okay so since limit y tending to 0, $V_y = 0$, we can choose the number delta which is $< \mu$ such that norm of y_0 is $\leq \delta$ here and V of y_0 is $< \mu$ here. So, it means that we are choosing norm of $y_0 < \delta$ and δ is $< \mu$.

So, it means that this norm of y_0 is $< \mu$ here, okay so we simply say that V of y_0 is $< \mu$ here, so here since the limit of y tending to 0, V of $y = 0$, so we can find out a number delta which is positive, such that norm of y is $< \delta$ and V of y_0 is $< \mu$ which we have define as minimum of V of y here, then according to 4, the solution $\phi(t)$ with the condition that $\phi(0) = y_0$ and norm of y_0 is $\leq \delta$, it satisfy the following equality that V of $\phi(t)$ is > 0 .

And it is $\leq V$ of y_0 and V of y_0 is $< \mu$, so here we assume that norm of y_0 is $\leq \delta$, where y_0 is nothing but $\phi(0)$, so this is true for $t < t_1$ here, but we already know that what is μ here, μ is the minimum of V of y , y belongs to S , then this implies that norm of $\phi(t)$ has to be $< \epsilon$ for t between 0 to t_1 here, why so because this implies that that $t_1 = + \infty$, first of all, since V of $\phi(t)$ is $< \mu$, you can look at here.

Then your $\phi(t)$ cannot be the element of S here and S is this annulus region, so it means that your $\phi(t)$ is somewhere outside this annulus, so either it will be here or it will be here now, since $\phi(t)$ is tending to 0, then this V of $\phi(t)$ is tending to 0, so it must be in a region which involved, which contain the origin, so it must be here, so it means that if $\phi(t)$ is here, so it means that norm of $\phi(t)$ must be $< \epsilon$ for, $t < \infty$; t lying between 0 and t_1 here.

So, and this also implies that $t_1 = \infty$ because if it is not, then we can find out a sometime $t_2 > t_0$, with the condition that $\|\phi(t_2)\| = \epsilon$, then for $t = t_2$, we also have from the definition of μ , we can say that since $\|\phi(t_2)\| = \epsilon$, so it means that V of $\phi(t_2)$ to and since μ is a minimum of all those; μ is a minimum of values of V over S and $\phi(t_2)$ is belonging to S , so it means that V of $\phi(t_2)$ is $\geq \mu$.

And V of $\phi(t_2)$ by 4, it is $\leq V$ of y_0 and V of y_0 is $< \mu$, so it means that this condition cannot hold true, so it means that we cannot have any point t_2 where norm of $\phi(t_2) = \epsilon$, so it means that norm of $\phi(t)$ is $< \epsilon$ and this t_1 is all the time + infinity, right.

(Refer Slide Time: 36:14)

Thus $t_1 = +\infty$ and corresponding to the given $\epsilon > 0$, we have found a $\delta > 0$ such that $\|y_0\| < \delta$ implies $\|\phi(t)\| < \epsilon$ for $0 \leq t < \infty$. Hence the proof.

So, it means that thus $t_1 = +\infty$ and corresponding to the given $\epsilon > 0$, we have found a $\delta > 0$ such that norm of y_0 is $< \delta$ implies that norm of $\phi(t)$ is $< \epsilon$ for $0 \leq t < \infty$ and hence the stability of the solution $\phi(t)$ is proved here, so solution here

the stability of zero solution is proved here, so it means that if given a system $\dot{x} = f(x)$ where f is smooth enough, then a zero solution of this, it means that $x(t)$ identically $= 0$ here.

We are assuming that $f(0) = 0$, so 0 solution of this system is stable provided that they exist a scalar continuous function V of x which is positive definite, so V of x is positive definite and \dot{V} of x is negative semi definite. So, here if you look at the expression of V of x is we have not said that it is somewhere related to $\dot{x} = f(x)$, so here our; how to find out V of x is up to us such that the \dot{V} of x , it is the derivative of Vx along the system $\dot{x} = f(x)$ satisfying this condition that it is negative semi definite.

Then your zero solution is stable solution, so if you look at these theorem, then here the important part is to construct this function V of x and here if you look at we have not obtained the solution of $\dot{x} = f(x)$, what we require is in finding the \dot{V} of x , the expression of f of x which is already given here, so without finding the solution of this dynamical system, we are able to predict the stability of zero solution here.

And hence sometimes we call this method as Lyapunov direct method for finding the stability of the zero solution. So with this, we conclude our this lecture and we will continue discussing some more result based on the Lyapunov function, so in next lecture, we will discuss some more properties telling about the asymptotically stability of zero solution and unstability of zero solution, in fact equilibrium solutions and how to construct Lyapunov function in some important cases, so with this we end here and thank you very much for listening, thank you.
