Lecture – 48
Lyapunov Stability Theory - II

Dear students. Welcome to the lecture on the Lyapunov stability theory II. So in the previous lecture, we have seen 2 theorems. One on the stability and the another on the asymptotically stability. So we have seen various conditions like positive definite function, the function of class K and decreasing function, etc. So in this lecture, initially we will see some examples of such functions and then we will proceed with the theorem on the instability of a dynamical system.

(Refer Slide Time: 01:03)

$V(x_1, x_2) = ax_1^2 + bx_2^2$, $a > 0, b > 0$ is a positive definite fun.
 $V(x_1, x_2) = ax_1^2 + b(1 - \cos x_2)$, $a > 0, b > 0$ " $x_1^2 + x_2^2 \leq 1$
 $V(x_1, x_2) = ax_1^2$, $a > 0$ positive semi-definite.
 $V(0, x_2) = 0$
 $V(x) \geq \phi(\|x\|)$
 $V(x_1, x_2) = 3x_1^2 + \frac{1}{2}x_2^2 \geq \frac{1}{2}(x_1^2 + x_2^2) = \phi(\|x\|) = \frac{1}{2}\|x\|^2$
 $V(x_1, x_2) = x_1^2 + (1 - \cos x_2) \geq \frac{1}{18}(x_1^2 + x_2^2)$

So if we consider the function V of say $x_1^2 + x_2^2 = ax_1^2 + bx_2^2$ where $a > 0, b > 0$. So this is a positive definite function. So it is very clear that V of 0, 0 is 0 and it is always positive. Similarly, second example like V of $x_1^2 + x_2^2$ if you say $ax_1^2 + b(1 - \cos x_2)$. So if you consider this example, when x_1 is 0 and x_2 is 0, the value is 0, b of 0, 0 is 0 and always the 2 values are positive.

If $a > 0, b > 0$, it is also positive definite function provided x_2 . For example, now if you consider this one, V of say x_1, x_2 , it is equal to simply ax_1^2 , a is positive. So this is positive semidefinite because V of 0, any x_2 is also equal to 0. For non-0 points, the function value is 0

and V of $0, 0$ is also equal to 0 . So it is positive semidefinite function. Now if you consider the, we have seen that if V is positive definite, then it should be greater than or equal to ϕ of norm of x where ϕ is a function of class K .

So we should show that for all these examples how to find this ϕ expression. So for example, if $V(x_1, x_2)$ is some expression, let us say $3x_1^2 + 1/2x_2^2$ square, so it is obviously positive definite function. And we can also see that it is greater than or equal to $1/2 * x_1^2 + x_2^2$ square. So it is the function ϕ of norm of x . So which is equal to the ϕ of norm of x function. That is nothing but $1/2$, you can say, norm x square, this x .

So this is the function. Similarly, for the function $V(x_1, x_2)$ which is equal to $x_1^2 + 1 - \cos x_2$. So as we have seen, it is positive definite function in some neighbourhood. So how to find a function ϕ for this one. So it can be verified that it is greater than or equal to $1/\pi x_1^2 + x_2^2$ square, which is the function ϕ , okay. So for any positive definite function, we can find the expression, a function of class K satisfying this condition. For the theorem 1, we consider how to find a Lyapunov function.

(Refer Slide Time: 05:00)

Consider

$$\begin{aligned} \dot{x}_1 &= x_2 \\ \dot{x}_2 &= -\alpha x_1 - \beta x_2 \quad ; \alpha > 0, \beta > 0 \end{aligned}$$

$(0,0)$ is equilibrium point.

$$V(x_1, x_2) = \alpha x_1^2 + x_2^2$$

$$\dot{V} = 2\alpha x_1 \dot{x}_1 + 2x_2 \dot{x}_2$$

$$= 2\alpha x_1 x_2 + 2x_2 (-\alpha x_1 - \beta x_2)$$

$$= -2\beta x_2^2 \quad \text{is -ve semi-definite}$$

\Rightarrow stability.

Let $V(x_1, x_2) = a^2 x_1^2 + b x_1 x_2 + c^2 x_2^2$
 $a > 0, c > 0, b > 2ac$

$$\begin{aligned} \dot{V} &= a^2 2x_1 \dot{x}_1 + b x_1 \dot{x}_2 + b x_2 \dot{x}_1 + c^2 2x_2 \dot{x}_2 \\ &= x_1 x_2 (2a^2 - \beta b - 2c^2 \alpha) \\ &\quad + b x_2^2 - b \alpha x_1^2 - 2c^2 \beta x_2^2 \end{aligned}$$

$$\left. \begin{aligned} 2a^2 - \beta b - 2c^2 \alpha &= 0 \\ b - 2c^2 \beta &< 0 \end{aligned} \right\}$$

$\Rightarrow \dot{V}$ is negative definite.

\Rightarrow The trivial sol $x=0$ is asympt stable.

So if we consider the system $\dot{x}_1 = x_2$ and $\dot{x}_2 = -\alpha x_1 - \beta x_2$. So if we consider this system, then $0, 0$ is an equilibrium point. If you equate the right hand side to 0 , we get this equilibrium point. So at this equilibrium point to analyze the stability, we have to find, if

possible, a Lyapunov function. So if we consider a Lyapunov function of this form, for example for this, if we consider, here $\alpha > 0$, $\beta > 0$.

So if we consider the Lyapunov function, $\alpha x_1^2 + x_2^2$, where α is given value in the system. Then it is a positive definite function and the \dot{V} that is the derivative $\frac{dV}{dt}$ that is $2\alpha x_1 \dot{x}_1 + 2x_2 \dot{x}_2$. So if you substitute from the equation, you will get $2\alpha x_1$, \dot{x}_1 is x_2 , $+2x_2$, \dot{x}_2 we substitute $\alpha x_1 - \beta x_2$. So we see that it gets cancelled, $2\alpha x_1 x_2$, remaining is $-2\beta x_2^2$.

So here it is \dot{V} is positive semidefinite, sorry negative semidefinite. It is negative semidefinite. So this implies stability. But we can see that this system is asymptotically stable because we can find some other Lyapunov function so that it is positive definite and \dot{V} is negative definite. So by this particular result, we should not conclude that the system is simply stable.

But if we keep trying for various types of Lyapunov function, we may conclude later that a given system is asymptotically stable also. Similarly, if you are not able to find a Lyapunov function, it does not mean that the system is unstable or we cannot conclude anything about the system just because we are not able to find a Lyapunov function. So for example, if you consider V of x_1, x_2 is $a x_1^2 + b x_1 x_2 + c x_2^2$.

So if we take a function like this in such a way that $b > 2ac$. So under this condition, it is clear that similarly a is positive, c is positive. So if you consider this, it is very clear that V of x_1, x_2 is always a positive value and V of $0, 0$ is 0 . So it is a positive definite function. Now by differentiating this, $\frac{dV}{dt}$, we will get the expression $2a x_1 \dot{x}_1 + b x_1 \dot{x}_2 + b x_1 \dot{x}_2 + 2c x_2 \dot{x}_2$.

Now if you substitute the values of \dot{x}_1, \dot{x}_2 from the given equation, we will get the expression to be like this. If you collect the coefficient of x_1, x_2 , we will get $2a^2 - \beta b - 2c$ square α , then we will get $+b^2 x_2^2 - b \alpha x_1^2 - 2c \beta x_2^2$. So we can see that if you select a, b, c properly, then we can make this bracket to be 0 . So that is we can

make $-2a$ square $b^2 - 2c$ square α .

If it is 0, then $x_1 * x_2$ term will become 0. And similarly, this $b^2 - 2c$ square β , if it is strictly less than 0, then the condition will give that \dot{V} is negative definite. So we can easily verify that such selection is always possible. So in this case, we can conclude that the system asymptotically stable or the trivial solution $x=0$ is asymptotically stable according to the theorem which we have seen in the previous lecture.

Theorem for Instability

Theorem

If there exists a scalar function $V(x) \in C^1[B_\rho, \mathbb{R}]$, $V(0) = 0$ such that $\dot{V}(x)$ is positive definite in B_ρ , and if in every neighborhood N of the origin, $N \subset B_\rho$, there is a point x_0 where $V(x_0) > 0$, then the trivial solution of the differential system $\dot{x}(t) = f(x) : f(0) = 0$ is unstable.

$$\left. \begin{array}{l} \dot{V} > 0 \\ \dot{V} > 0 \end{array} \right\} \Rightarrow \text{unstable} \rightarrow x \rightarrow 0$$

$$\left. \begin{array}{l} \dot{V} < 0 \\ \dot{V} < 0 \end{array} \right\} \Rightarrow \text{unstable} \rightarrow x \rightarrow 0$$

2

So now we will come to the following theorem on instability. So here if you can find a function V of x which is continuously differentiable in the ball of radius ρ and $V(0) = 0$ and it also satisfies dV/dt is positive definite in B_ρ . Moreover, if in every neighbourhood N of the origin, there exist a point x_0 such that $V(x_0)$ is positive, then the trivial solution is unstable here.

So the theorem says that we consider, for example in the case of 2 variables, x is x_1, x_2 in \mathbb{R}^2 , then in every neighbourhood, whichever neighbourhood we take however small it is, there exist at least one point x_0 so that $V(x_0)$ is positive, the value is positive at the point x_0 . And \dot{V} is positive definite, okay. So in that case, we conclude that the system will be unstable. So it also implies that if V is positive definite, that is for each and every point, V is positive value and \dot{V} is also positive definite, then also it is unstable.

That is a particular case. Here more general case is if at some point in every neighbourhood, V is positive and \dot{V} is positive definite, then the system is unstable. So the same theorem can be reversed. If \dot{V} is negative definite and in every neighbourhood, we can find a point x_0 so that V of x_0 is also negative, then the system again is unstable.

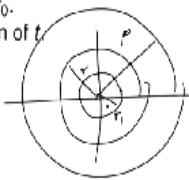

So we can also say if V is positive definite, not at some point but at all the points and \dot{V} is also positive definite, this implies the system is unstable. And if V is negative definite, \dot{V} is also negative definite, that is also implies unstable at the critical point x , identically 0. And this is the more general statement. The theorem gives more general statement here.

(Refer Slide Time: 15:26)

Proof

Let $r < \rho$ so that $B_r \subset B_\rho$. Let $M = \max_{B_r} V(x)$.
 Let $0 < r_1 < r$, then by assumption there exists a point $x_0 \in B_{r_1}$ such that $\|x_0\| < r_1$ and $V(x_0) > 0$.
 Let $x(t)$ be a solution of a system with initial condition $x(0) = x_0$.
 Given that $\dot{V}(x(t)) > 0$. Hence $V(x(t))$ is an increasing function of t .

$\therefore 0 < V(x(0)) < V(x(t)), t > 0$
 $\therefore x(t)$ can not tend to 0.

3

So to prove that statement, let us consider $r < \rho$ and B_r is subset of B_ρ . So if you consider a ball of radius ρ and a smaller ball of radius r here. And V is we have mentioned that V is a continuously differentiable function. Therefore, it will be bounded. So there will be a maximum value for V in the ball of radius r , okay, maximum value is there. So we select another number r_1 strictly less than r and take a point x_0 in the ball of radius r_1 , smaller radius r_1 as the initial condition.

So for this initial condition x_0 , x of t is a solution of the problem. There exists a unique solution for every initial condition. So x of t is a solution. And it is given that \dot{V} is positive definite

function, is greater than 0. Hence, V of x of t is an increasing function of t . So this dV/dt is positive. It implies that V of x of t is an increasing function of t . So if $0 < t$, that is for $t > 0$, we have V of x of 0 should be less than V of x of t because of the increasing nature for all $t > 0$.

Therefore, x of t cannot tend to 0 according to this result that V of x of 0, that is V of x_0 is the value of the function V at the point x_0 , that is a positive value. And that is less than V of x of t , that means V of x of t is bigger than this positive value. So as t becomes larger and larger, V of x of t cannot become 0. But V is 0 only at the point 0. Therefore, x of t cannot tend to the value 0.

(Refer Slide Time: 18:08)

Hence,

$$\min_{t>0} \dot{V}(x(t)) = m > 0$$

$$\therefore \dot{V}(x(t)) \geq m, \text{ for all } t > 0$$

$$\therefore V(x(t)) \geq V(x(0)) + mt.$$

For large value of t the RHS can be made $\geq M$.
This implies that the solution $x(t)$ goes out of the neighborhood B_ρ . Hence the zero solution is unstable.

And therefore, the minimum value of the V dot x of $t=m$ here in this case and so we can write V dot x of t is greater than or equal to m and integrating, we get V of x of $t \geq V$ of x of $0 + m \cdot t$. Integrating from 0 to t , we get this expression. From this for large value of t , the right hand side can be made to be greater than M where M is the maximum value which was defined here on this ball.

So it means that the, this implies that x of t goes out of the neighbourhood B_ρ here. The maximum is defined on B_r . And because the value of V is exceeding the value M , it means that the solution x of t goes out of the neighbourhood B_r . it is not ρ , actually it should be corrected. It is B_r . Hence the system is unstable. That is starting from initial condition, the solution goes out of the ball. Any, whatever ball we are selecting of radius r , it will be going out of that one. So the

system is unstable because of the condition given here.

(Refer Slide Time: 19:41)

Ex: $\dot{x}_1 = x_1^2 - x_2^2$
 $\dot{x}_2 = -2x_1x_2$
 $V(x_1, x_2) = 3x_1x_2^2 - x_1^3$
 $= x_1(3x_2^2 - x_1^2)$
 $\dot{V}(x_1, x_2) = -9x_1^2x_2^2 - 2x_2^4 + 3x_1^2x_2^2 - 3x_1^4$
 $= -6x_1^2x_2^2 - 3x_1^4 - 3x_2^4 < 0$

The slide also features a small diagram of a coordinate system with axes labeled x_1 and x_2 , and a circle centered at the origin.

So here for example, we can consider the following. For example, let us consider $\dot{x}_1 = x_1^2 - x_2^2$ and $\dot{x}_2 = -2x_1x_2$. So this is a dynamical system. Now it is very clear that $(0, 0)$ is the equilibrium point for the system. Now if you define a function $V(x_1, x_2)$ in this form, that is $3x_1x_2^2 - x_1^3$. So let us take this function it is given. So using this function or we can write it like this, $x_1(3x_2^2 - x_1^2)$.

So we can see that this function has in the neighbourhood of the origin at $(0, 0)$, if you take any neighbourhood, for points in this neighbourhood, we can see that at some point, it may be positive; at some point, it may be negative. So any neighbourhood we select, we can find some point x_1, x_2 for which V of x_1, x_2 is positive or negative in anyway. Now we can easily calculate the dV/dt , \dot{V} of x_1, x_2 . So that will give the value like this.

If you select it finally, after substituting the values of \dot{x}_1 and \dot{x}_2 and after the derivative, we will get an expression like this $-9x_1^2x_2^2 - 2x_2^4 + 3x_1^2x_2^2 - 3x_1^4$. So ultimately, we will get everything negative, $-6x_1^2x_2^2 - 3x_1^4 - 3x_2^4$ to the power 4. So this is strictly less than 0 for all the values of x_1 and x_2 in the neighbourhood of $(0, 0)$.

So this implies according to the theorem, the statement of the theorem. The statement of the theorem says that if in the neighbourhood, it is positive and \dot{V} is also positive, the system is unstable. The reverse is if in the neighbourhood if V of x_0 is negative and \dot{V} is also negative definite, then the system is unstable. So that is the case which we are having here. In every neighbourhood, we can have a negative value for V and \dot{V} is negative definite.

So this implies 0 is unstable, $x=0$ is unstable according to this particular theorem. So in the next lecture, we will see the stability theorem for time varying system. So far we have seen the theorems for time invariant system and now similar theorems with some modifications are available for time varying system. So that we will see in the next lecture. Thank you.
