**Optimal Control for Discrete Systems-I**

**(Refer Slide Time: 00:33)**

Let  $x(k) \in \mathbb{R}^n$  for  $k = k_0, k_0 + 1, \dots, k_0 + N, \dots$  and  $F : \mathbb{R}^n \times \mathbb{R}^n \times \mathbb{R}^m \rightarrow \mathbb{R}$  be a functional. Let  $J(k_0)$  be a functional defined as

$$J(k_0) = \sum_{k=k_0}^{k_0+N-1} F(x(k), x(k+1), k) \quad (1)$$

To find the extremum value of the functional  $J(k_0)$  and the corresponding optimal solution (sequence)  $x(k) : k = k_0 + 1, k_0 + 2, \dots, k_0 + N$ , the necessary condition is that the first variation of  $J$  is zero.

$$\delta J(k_0) = 0.$$

Hello viewers, welcome to this lecture on optimal control for discrete systems, in this lecture before going to the optimal control problems, we will find the procedure for optimising the functional  $J$  of  $k_0$  given by this expression, summation  $k$  ranges from  $k_0$  to  $k_0 + \text{capital } N - 1$  of the function capital  $F$  of  $x_k, x_{k+1}, k$ , so this function capital  $F$  is a function from  $\mathbb{R}^n$  cross  $\mathbb{R}^n$  cross  $\mathbb{R}^m$  here, so this is to be cancelled.

So, it is a real valued function of vectors from  $\mathbb{R}^n$  and  $x_k$  is a sequence of vectors where  $k$  ranges from  $k_0, k_0 + 1$  etc. So, we have to find a sequence of vectors  $x_k$  which minimises the expression  $J$  of  $k_0$ , in some problem it may maximise, so in this lecture we will find this necessary condition for finding the optimum value of this expression. So, the necessary condition may provide the either maximum or minimum value.

**(Refer Slide Time: 02:07)**

First, we discuss the result for scalar function  $x(k)$  :

**Theorem**

The Euler-Lagrange equation for the minimization of (1) is given by

$$\frac{\partial F(x(k), x(k+1), k)}{\partial x(k)} + \frac{\partial F(x(k-1), x(k), k)}{\partial x(k)} = 0 \quad (2)$$

with boundary condition

$$\frac{\partial F(x(k-1), x(k), k-1)}{\partial x(k)} \delta x(k) \Big|_{k_0}^{k_0+N} = 0 \quad (3)$$

Or it may not provide any of this also because it is only a necessary condition, so for finding the optimum value of J, the necessary condition is the variation in J should be = 0, del J of this expression = 0, so to calculate this del J, we will obtain the necessary condition as follows, given in this theorem the Euler Lagrange equation for the minimisation of the expression 1 is given by this expression.

The partial derivative of F of  $x_k$   $x_k - k$  with respect to  $x_k +$  the partial derivative of the function, F of  $x_k - 1$   $x_k$   $k$  with respect to del  $x_k$  that should be = 0, this is a necessary condition, the boundary conditions are given by this expression, the partial derivative of F, F of  $x_k - 1$  F of  $x$  of  $k$   $k - 1$  / del  $x_k$ , this has to be equal to 0. Now, we can observe that the boundary condition for example, if the initial and final conditions are fixed, initial instant is  $k_0$ ; final instant is  $k_0 + N$ .

So, if the 2 conditions are already given in the problem, then the variation will be 0 at these two points, so this condition is not required, in case that the, these are variables, the initial position  $x$  of  $k_0$  and final position  $x$  of  $k_0 + N$  are variables, then the variation will be arbitrary, in that case we will get a boundary condition given by this, del F/ del  $x$  at these 2 points should be = 0, so that we will see during the example.

**(Refer Slide Time: 04:16)**

**Proof:**

Let  $x^*(k) : k = k_0, k_0 + 1, \dots, k_0 + N$  be the optimal solution.  
 A variation of  $x^*(k)$  and  $x^*(k + 1)$  is written as

$$\begin{aligned} x(k) &= x^*(k) + \delta x(k) \\ x(k + 1) &= x^*(k + 1) + \delta x(k + 1) \end{aligned} \quad (4)$$

Now let

$$J = \sum_{k=k_0}^{k_0+N-1} F(x^*(k), x^*(k + 1), k) \quad (5)$$

$$\text{and } J^\delta = \sum_{k=k_0}^{k_0+N-1} F(x^*(k) + \delta x(k), x^*(k + 1) + \delta x(k + 1), k) \quad (6)$$

So, let us see how to derive this necessary condition, so if  $x^* k$  is an optimal sequence in between the instant  $k_0$  to  $k_0 + N$ , then the variation is given by this expression, so we note that first we derived this theorem for the case, where  $x$  of  $k$  are not vectors, they are scalar functions, so the same expression can be derived later for the vector functions, so that can be easily generalised.

So, right now we are assuming that  $F$  is a function of this real valued function,  $x_k, x_{k + 1}$  and  $k$  is a real number and so now,  $x$  of  $k$ ;  $x^* k$  is a optimal sequence, so the variation in  $x^* k$  is given by  $\delta x_k$ , so it gives a new sequence,  $x$  of  $k$  and  $x_{k+1}$  is the sequence starting from  $x^* k + 1 + \delta x$  of  $k + 1$ , so see if you assume that for the real case,  $k_0, k_0 + 1$  etc.  $k_0 + N$ , so the optimal value at  $k_0$   $x$  of  $k_0$  is a number,  $x$  of  $k_0 + 1$ ,  $x$  of  $k_0 + 2$ .

So, if you have some sequence like this, this is our optimal solution now, if you give a variation in the first value, it may be a small variation here, positive variation and there may be a negative variation like this, so we may get a new function which may be given by this expression, so it is  $a$ ; it is like  $x$  of  $k$ , if this we are assuming to be  $x^*$  of  $k$  for various values, a small increment will give you a new function  $x$  of  $k$ , this sequence.

And similarly, if you start from the next value for example, if you start from  $k + 1$  that is another sequence, which is given by  $x$  of  $k + 1$ , now the  $J$  value which we want to minimise is given by

this expression starting from  $k_0$  to  $k_0 + N - 1$  of this function and after giving the increment in  $x^*$ , we get the function,  $J + \delta J$ .

**(Refer Slide Time: 07:35)**

and

$$\delta J = J^\delta - J. \quad (7)$$

Using the Taylor series expansion of (6) along with (5), we have

$$\delta J = \sum_{k=k_0}^{k_0+N-1} \left[ \frac{\partial F(x^*(k), x^*(k+1), k)}{\partial x^*(k)} \delta x(k) + \frac{\partial F(x^*(k), x^*(k+1), k)}{\partial x^*(k+1)} \delta x(k+1) \right]. \quad (8)$$

Now in order to express the coefficient  $\delta x(k+1)$  also in terms of  $\delta x(k)$ , consider the second expression in (8)

So, the first variation in  $J$  is;  $\delta J = J^\delta - J$  and which can be written like this by directly substituting the values from here,  $J^\delta$  is this,  $J$  is this, subtract these 2, we get this expression. Now, if you write the Taylor series expansion of; so the first variation in  $J$  is given by  $J^\delta - J$  and if you observe from the previous slide,  $J^\delta$  is the expression 6, now it is having  $F$  of  $x^* + \delta x$  and  $x^* k + 1 + \delta x$  of  $k+1$ ,  $k$ .

Now, expanding this expression in the Taylor series and taking only the first variation in the Taylor series, so we will see that the first term of the Taylor series is same as  $J$  and  $J^\delta - J$ , in that the first term will get cancelled, the second term is the first variation given from the equation 6, which is nothing but  $\frac{\partial F}{\partial x}$  of  $k * \delta x$  of  $k$ . Similarly, the derivative; partial derivative  $\frac{\partial F}{\partial x}$  of  $k+1$  multiplied by the first variation  $\delta x$  of  $k+1$ .

So that is what we will get here, the  $\frac{\partial F}{\partial x}$  of  $x^* k$  and  $\frac{\partial F}{\partial x}$  of  $x^* k + 1$  term, only first variation we are collecting and omitting all the second variation, we get  $\delta J$  to be like this and this should be  $= 0$  is the necessary condition but from here, we may not get any useful result.

**(Refer Slide Time: 09:40)**

$$\begin{aligned}
& \sum_{k=k_0}^{k_0+N-1} \frac{\partial F(x^*(k), x^*(k+1), k)}{\partial x^*(k+1)} \delta x(k+1) \\
&= \frac{\partial F(x^*(k_0), x^*(k_0+1), k_0)}{\partial x^*(k_0+1)} \delta x(k_0+1) \\
&+ \frac{\partial F(x^*(k_0+1), x^*(k_0+2), k_0+1)}{\partial x^*(k_0+2)} \delta x(k_0+2) \\
&+ \dots \\
&+ \frac{\partial F(x^*(k_0+N-2), x^*(k_0+N-1), k_0+N-2)}{\partial x^*(k_0+N-1)} \delta x(k_0+N-1) \\
&+ \frac{\partial F(x^*(k_0+N-1), x^*(k_0+N), k_0+N-1)}{\partial x^*(k_0+N)} \delta x(k_0+N)
\end{aligned}$$

So, we can further proceed like this, we take the second term, the second term is  $\partial F / \partial x_{k+1}$  and we write the entire the summation, summation  $k = k_0 + 1$  to  $k_0 + N - 1$  for the second term, so if you expand it term by term, we get this expression, for  $k = k_0$  is the first term,  $k_0 + 1$  is the second term etc. the last term is for  $k_0 + N$ .

**(Refer Slide Time: 10:21)**

$$\begin{aligned}
& + \frac{\partial F(x^*(k_0-1), x^*(k_0), k_0-1)}{\partial x^*(k_0)} \delta x(k_0) \\
& - \frac{\partial F(x^*(k_0-1), x^*(k_0), k_0-1)}{\partial x^*(k_0)} \delta x(k_0) \tag{9}
\end{aligned}$$

And then we add this term and subtract this term that for convenience,  $\partial F$  of  $x^*_{k_0-1}$   $x^*_{k_0}$   $k_0-1$  term we add and then subtract the same thing now, we can combine this term except the starting from the first term to this term, we can write it in the particular form, so  $k_0$  to  $k_0 + N - 1$   $\partial F$  of  $x^*_{k-1}$   $x^*_k$   $k-1 / \partial x^*_k$  etc. and while writing like this we are omitting this term that is the last term.

Because you are writing it in the form of  $k-1$  appearing first here, we observe that the first values are  $F$  of  $x$ ;  $x$  star of  $k_0$  but when we write it in the form of  $k_0-1$  as the first term.

**(Refer Slide Time: 11:32)**

where the last two terms in (9) are added without affecting the rest of the equation.

$$\begin{aligned}
 &= \sum_{k=k_0}^{k_0+N-1} \frac{\partial F(x^*(k-1), x^*(k), k-1)}{\partial x^*(k)} \delta x(k) \\
 &\quad + \frac{\partial F(x^*(k_0+N-1), x^*(k_0+N), k_0+N-1)}{\partial x^*(k_0+N)} \delta x(k_0+N) \\
 &\quad - \frac{\partial F(x^*(k_0-1), x^*(k_0), k_0-1)}{\partial x^*(k_0)} \delta x(k_0)
 \end{aligned}$$

So, we have to note that while doing that way, we will be omitting the last term in that previous series and this term we have already introduced artificially in the last step, so this 2 terms are omitted and this summation takes care of all the other terms. See, this last term is not there inside the summation and this last term is also not there in the summation, so we take this term as well as this minus term and combining this 2 here separately, we get the entire expression which we want here, okay.

**(Refer Slide Time: 12:26)**

$$\begin{aligned}
&= \sum_{k=k_0}^{k_0+N-1} \frac{\partial F(x^*(k-1), x^*(k), k-1)}{\partial x^*(k)} \delta x(k) \\
&\quad + \left[ \frac{\partial F(x^*(k-1), x^*(k), k-1)}{\partial x^*(k)} \delta x(k) \right]_{k=k_0}^{k=k_0+N}. \quad (10)
\end{aligned}$$

Substituting (10) in (8) and noting that the first variation should be zero, we have

$$\begin{aligned}
\sum_{k=k_0}^{k_0+N-1} \left[ \frac{\partial F(x^*(k), x^*(k+1), k)}{\partial x^*(k)} \delta x(k) + \frac{\partial F(x^*(k-1), x^*(k), k-1)}{\partial x^*(k)} \delta x(k) \right] \delta x(k) \\
+ \left[ \frac{\partial F(x^*(k-1), x^*(k), k-1)}{\partial x^*(k)} \delta x(k) \right]_{k=k_0}^{k=k_0+N}. \quad (11)
\end{aligned}$$

So, the second term was written in that particular form, the first term is as it is, so combining the first term of the equation 8 and second term of 8 together, we will write the equation to be like this, these are the expression we get,  $\frac{\partial F}{\partial x^*(k)}$  of  $x^*(k-1)$   $x^*(k)$   $k-1$  /  $\frac{\partial F}{\partial x^*(k)}$  \* the variation  $x$  of  $k$  and the last two terms, extra terms which we have taken is written in this particular form.

So, combine, this is only the second term of the necessary condition, the first of term is here as it is so, combining the first term and the second term together, we get this and the boundary condition term is given in this way. So, now the variation  $\delta x_k$  is arbitrary, this entire bracket has to be = 0 here and for the boundary condition, we have to; because once the bracket becomes 0, the remaining gives the boundary condition for the solution of the problem.

**(Refer Slide Time: 13:29)**

For arbitrary variations  $\delta x(k)$ , we have the condition that the coefficient of  $\delta x(k)$  in the first term in (11) be zero. we have

$$\frac{\partial F(x^*(k), x^*(k+1), k)}{\partial x^*(k)} + \frac{\partial F(x^*(k-1), x^*(k), k-1)}{\partial x^*(k)} = 0. \quad (12)$$

This equation is called as the discrete-time version of the Euler-Lagrange equation. The boundary condition is obtained by setting the second term in (11) equal to zero. That is

$$\left[ \frac{\partial F(x^*(k-1), x^*(k), k-1)}{\partial x^*(k)} \right]_{k=k_0}^{k=k_0+N} = 0. \quad (13)$$

$x(k_0)$   
 $x(k_0+N)$

So, we get the necessary condition to be like this,  $\frac{\partial F(x_k, x_{k+1}, k)}{\partial x^*(k)} + \frac{\partial F(x_{k-1}, x_k, k-1)}{\partial x^*(k)} = 0$  is a necessary condition and the boundary condition is given by this expression, this bracket.

**(Refer Slide Time: 14:00)**

Now, we discuss two important cases:

- **Case 1:** For fixed end conditions, we have the boundary condition  $x(k_0)$  and  $x(k_0 + N)$  fixed and hence  $\delta x(k_0) = \delta x(k_0 + N) = 0$ .
- **Case 2:** If  $x(k_0)$  is given and  $x(k_0 + N)$  is free then  $\delta x(k_0) = 0$  and

$$\left[ \frac{\partial F(x^*(k-1), x^*(k), k-1)}{\partial x^*(k)} \right]_{k=k_0+N} = 0 \quad (14)$$

So, now depending on the case, if the boundary conditions both of them are fixed values, then the variation at this 2 boundary will be 0, here, the variation,  $\delta x_k$ ; then it should be  $\delta x_k$  also, so this correction also we have to note, okay, equation 13, so this  $\delta x_k$ , if the initial time  $k$  at  $k_0$  and  $k_0 + N$ , if  $x$  of  $k_0$  is given,  $x$  of  $k_0 + N$ , if both are given, then the variation at this 2 points will be 0, so this condition is not required only the equation 12 to be solved under this boundary

conditions but in case  $x$  of  $k_0$  is given but the final position is not given, final time is given,  $k_0 + N$ .

But  $x$  of  $k_0 + N$  is not given and it is free then, we need the boundary condition from here because the variation  $\delta x$  of  $k_0 + N$  will be arbitrary in that case so, we get a condition  $\delta F / \delta x^*$  evaluated at  $k_0 + N$  should be  $= 0$  will turn out to be the boundary condition for such problem. So, for the case 1 we have to solve only the equation 12 with the given boundary condition.

And in the case 2 where  $x$  of  $k_0$  is given and the other one is free, then we get this boundary condition.

**(Refer Slide Time: 16:01)**

Now, we consider the conditions for the case in which  $x(k)$  is vector function. Thus, consider the functional which is the vector version of the scalar functional (1) as

$$J(k_0) = \sum_{k=k_0}^{k_0+N-1} F(\mathbf{x}(k), \mathbf{x}(k-1), k) \quad (15)$$

$\mathbf{x}(k) \in \mathbb{R}^n$  for each  $k$

$$\frac{\partial F(\mathbf{x}^*(k), \mathbf{x}^*(k+1), k)}{\partial \mathbf{x}_i^*(k)} + \frac{\partial F(\mathbf{x}^*(k-1), \mathbf{x}^*(k), k-1)}{\partial \mathbf{x}_i^*(k)} = 0. \quad (16)$$

$$\left[ \frac{\partial F(\mathbf{x}^*(k-1), \mathbf{x}^*(k), k-1)}{\partial \mathbf{x}_i^*(k)} \right]_{k=k_0}^{k=k_0+N} = 0 \quad (17)$$

$\mathbf{x}(k) = \begin{pmatrix} x_1(k) \\ x_2(k) \\ \vdots \\ x_n(k) \end{pmatrix}$

$i = 1, 2, \dots, n.$

So, far what we have seen is the derivation of the equation; this 2 equation 12 and 13 where  $x$  of  $k$  is a real number, the sequence  $x$  of  $k$  is a real sequence but in case,  $x$  of  $k$  is a vector sequence, each  $x$  of  $k$  belongs to  $\mathbb{R}^n$ , so if  $x$  of  $k$  belongs to  $\mathbb{R}^n$  for each  $k$  value, then also the procedure is same, only thing is  $x$  of  $k$  is written as  $x_1$  of  $k$   $x_2$  of  $k$  etc.  $x_n$  of  $k$ , it is a vector, so at every stage we have to replace the real value with the vector.

And then the partial derivative of this function with respect to each value should be considered, so for  $i = 1, 2, 3$  up to  $n$ , we can; we get this 2 formulas, instead of 12 and 13 formula, we get 16

and 17 for each variable  $x_i$ , each variable  $x_i$ , okay, the same formula, so the procedure will be the same exactly, so now we will consider a simple problem of finding the optimum value, optimum sequence.

**(Refer Slide Time: 17:31)**

Find the optimal sequence for minimizing the functional

$$J(k_0) = \sum_{k=k_0}^{k_0+2} [x(k)x(k+1) + x^2(k+1)]$$

Under the condition  $x(k_0) = 1$ ,  $x(k_0+3) = 4$ .

Solution: Solve.

$$F(k) = x(k)x(k+1) + x^2(k+1)$$

$$F(k-1) = x(k-1)x(k) + x^2(k)$$

$$\frac{\partial F(k)}{\partial x(k)} + \frac{\partial F(k-1)}{\partial x(k)} = 0$$

$$[x(k+1)] + [x(k-1) + 2x(k)] = 0 \dots (1)$$

$$k = k_0+1 \quad x(k_0+2) + x(k_0) + 2x(k_0+1) = 0 \dots (2)$$

$$k = k_0+2 \quad x(k_0+3) + x(k_0+1) + 2x(k_0+2) = 0 \dots (2)$$

So, find the optimal sequence for minimising the functional  $J(k_0)$ ,  $k_0$  indicates that that is the initial instant, so if it is given by this expression  $x$ ;  $x^2(k_0+3) + \text{summation}$ , so it is summation  $k = k_0+2$  of; so, let us consider the function  $J$ , yeah, so in this problem, we consider the functional  $J$  of  $k_0$  is given by summation  $k$  starting from  $k_0$  to  $k_0+2$  and the expression is  $x$  of  $k$  and  $x$  of  $k+1 + x^2$  of  $k+1$ .

So, we have to minimise this expression and so, it means under the condition  $x$  of  $k_0$  is 1 and  $x$  of  $k_0+3$  is some value, this 2 values are given, so we have to find  $k_0+1$ ,  $k_0+2$ ,  $k_0+3$ , so 4 instant of time is given,  $x$  of  $k_0$  is fixed, it this 1 and  $k_0+3$  is also given, it is the value 4, now we have find the values for this  $k_0+1$ ,  $k_0+2$ , 2 values we have to find, so the optimum solution it may lie anywhere in this line, the values can be anywhere here, only initial and final are given.

So, if you solve the equation  $\frac{\partial F}{\partial x}$ ; the solution, we have to solve the 2 equation which we have mentioned in the previous slide, so that is  $\frac{\partial F}{\partial x}$ , when  $F$  is starting with  $x$  of  $k$  and  $\frac{\partial F}{\partial x}$ , if  $F$  is starting with  $k-1$ , so here  $F$ , we can write, if it is starting with  $k$ , it is the given

expression,  $x$  of  $k$   $x$  of  $k + 1 + x$  square of  $k+1$  and when it the initial thing is starting with  $k -1$ , it is  $x$  of  $k - 1$   $x$  of  $k + x$  square of  $k$ .

So, the necessary condition is  $\frac{\partial F}{\partial k} + \frac{\partial F}{\partial x} = 0$ , so that is the condition, okay as given here and we do not require the boundary condition 17 because both boundaries are fixed here, so we simply write  $\frac{\partial F}{\partial k}$ , derivative with respect to  $k$ , it is  $x$  of  $k +1$  and  $\frac{\partial F}{\partial x}$ , if you differentiate this with respect to  $k$ , so this is the first one, the second one is with respect to  $x$ , we get  $x$  of  $k -1+2$  times  $x$  of  $k$ .

So, this = 0, now we put  $k = k_0 +1$  in this equation, we will get  $x$  of  $k_0 +1 + 1$   $k_0 +2 + x$  of  $k_0$  and  $+ 2$  times  $x$  of  $k_0 + 1$  that is = 0 and when we put  $k = k_0 +2$  in this equation, we get  $x$  of  $k_0 +3 + x$  of  $k_0 +1+2$  times  $x$  of  $k_0 + 2 = 0$ , so we get this 2 equation and it is already given,  $x$  of  $k_0$  is 1, so we have to solve this 2 equation, from equation 1, we will get the relation between  $x$  of  $k_0 + 2$  and  $k_0 + 1 = 0$ .

And  $k_0 + 3$ ,  $x$  of  $k_0 + 3$  is given as 4, so we substitute it in the equation 2, so that gives you  $4 + x$  of  $k_0 + 1$  2 times  $x$  of  $k_0 +2 = 0$ , so we get 2 equations with 2 unknowns, the 2 unknowns are  $x$  of  $k_0 + 1$  and  $x$  of  $k_0 + 2$  in this equation, so we get the solution, solving this 2 algebraic equation, we get the optimal value of this thing of the 4 values are given, so we will get some value for  $x$  of  $k_0 +1$  and some value for  $x$  of  $k_0 +2$ , already  $x$  of  $k_0 +3$  is given.

So, this sequence is the optimal sequence which will optimise the expression  $J$  of  $k_0$  under this condition, okay. Now, if the final condition is not given let us assume that the initial condition  $x$  of  $k_0$  is given but final condition is free, so that we can solve by this expression.

**(Refer Slide Time: 25:56)**

$$J(k) = \sum_{k=k_0}^{k_0+2} [x(k)x(k+1) + x^2(k+1)] \quad \left. \begin{array}{l} \text{Find the Optimal} \\ \text{Sequence} \\ x(k_0+1), x(k_0+2), \\ x(k_0+3) \end{array} \right\}$$

under  $x(k_0) = 1$   $x(k_0+3)$  is free.

Solution:  $\frac{\partial F(k)}{\partial x(k)} + \frac{\partial F(k-1)}{\partial x(k)} = 0$

under the conditions  $x(k_0) = 1$   
 $\frac{\partial F(k-1)}{\partial x(k)} \Big|_{\text{at } k_0+3} = 0$

$F(k-1) = x(k-1)x(k) + x^2(k) = 0 \Rightarrow x(k_0+2) + 2x(k_0+3) = 0$

$\frac{\partial F(k-1)}{\partial x(k)} \Big|_{\text{at } k_0+3} = (x(k-1) + 2x(k)) \Big|_{\text{at } k_0+3}$

$\left. \begin{array}{l} x(k_0+1) \\ x(k_0+2) \\ x(k_0+3) \end{array} \right\}$

So, now a second example we will see, the example in which the boundary condition is variable, so here we consider  $k$  varies from  $k_0$  to  $k_0 + 2$  of  $x$  of  $k$   $x$  of  $k+1 + x$  square  $k+1$ , so you have to minimise this expression under the condition  $x$  of  $k_0$  is some given value and  $x$  of  $k_0 + 3$  is free, so which is not given, so in that case we have to solve, so for this problem, we have to find the optimal sequence.

We have to find  $x$  of;  $x$  of  $k_0$  is already given, we have to find  $k_0 + 1$   $x$  of  $k_0 + 2$   $x$  of  $k_0 + 3$ , this 3 values we have to find to minimise or maximise this expression, so we have; the solution is; we have to solve the equation  $\text{del } F$ , if it is starting with  $x_k$  and differentiate with respect to this and  $\text{del } F$ , if we start with  $k-1$  and we differentiate this  $= 0$  under the boundary condition,  $x$  of  $k_0$  is already 1, it is given.

And because the second boundary condition is free from the expression here, we will see that the  $\text{del } F$  starting with  $k-1$  derivative with respect to  $x$  of  $k$  at the endpoint that should be  $= 0$ , so we have the boundary condition,  $\text{del } F$  starting with  $k-1$  term of  $\text{del}$  of  $x_k$  evaluated at  $k_0 + 3$  that should be  $= 0$ , so this is the problem, so if you write the; the equation will be the same because the problem expression is the same as in the previous slide here.

So, this 2 equation will be the same, only thing is the boundary condition we have to substitute this expression, so  $\text{del } F$   $x$  of; if you write  $K-1$  that term is nothing but  $x$  of  $k-1$  and  $x$  of  $k+x$

square of  $x$ , we differentiate with respect to  $\Delta x$  of  $k$ , so that gives  $x$  of  $k-1+2$  times  $x$  of  $k$ , so if you evaluate at  $k_0+3$ , so this evaluated at  $k_0+3$  should be  $= 0$ , so this implies  $x$  of  $k_0+3-1$ , so it is  $k_0+2$  and  $+ 2$  times  $x$  of  $k_0+3$  here that is  $= 0$ .

So, we get a relation between  $k_0+2$  and  $k_0+3$  and already we have the 2 equation; equation number 1 and 2 here, so we substitute the relation the, this relation between  $k$ ;  $x$  of  $k_0+2$  and  $k_0+3$ , we can write one in terms of the other, so that will reduce one of the variables and we can solve the system using the initial condition by substituting  $x$  of  $k_0 = 1$  in this 2 system of equation; equation 1 and 2.

And making use of this boundary condition at  $k_0+3$ , we can solve the algebraic equation easily and obtained the optimal sequence for the 3 values that is  $x$  of  $k_0$  is already given, we want to find  $x$  of  $k_0+1$   $k_0+2$   $k_0+3$ , so this sequence is obtained by solving the simple algebraic system, so in this lecture we have seen the optimisation of a discrete expression, discrete time expression and the optimum sequence, how to find the optimum sequence to minimise  $J$  has been shown that is a necessary condition has been shown here.

And in the next lecture, we will consider the optimal control problems that is along with minimisation of  $J$ , the constraint is a discrete control system and we will find the optimal control for the discrete time systems, thank you.
