Lecture – 11
Winding Number and Maximum Modulus Principle

Hello friends, welcome to my lecture on winding number and maximum modulus principle. Suppose that γ is the closed contour in the complex plane okay and C be a given point is $C - \gamma$ okay.

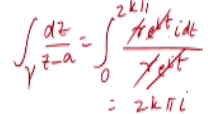

(Refer Slide Time: 00:42)

Suppose that γ is the closed contour in C . Let ' a ' be a given point in $C \setminus \gamma$. For instance, let $\gamma = \gamma(t) = \{z : z - a = re^{it}, 0 \leq t \leq 2k\pi\}$, then γ encircles the point ' a ', k times (counterclockwise). Further,

$$\int_{\gamma} \frac{dz}{z-a} = 2k\pi i$$

$$\Rightarrow \frac{1}{2\pi i} \int_{\gamma} \frac{dz}{z-a} = k. \checkmark$$

Hence, if γ encircles the point ' a ' k -times in the clock-wise direction, then

$$\frac{1}{2\pi i} \int_{\gamma} \frac{dz}{z-a} = -k. \checkmark$$

So let us take a close contour C okay. Let γ be a close contour in C okay and a be a given point in $C - \gamma$ okay. So this is a is any given point here okay which does not belong to γ okay. It can be either inside γ or it is outside γ , for instance let us say $\gamma = \gamma(t)$, that is this sort of all complex number z such that $z - a = r e^{it}$ where $0 \leq t \leq 2k\pi$.

So by this we are actually considering here γ to be the circle with center at a and radius r . So here we are considering the particular case where this a is inside the circle okay, γ and the circle, equation of the circle γ is $z - a = r e^{it}$. Now t varies from 0 to $2k\pi$, this means that we are moving along γ k times okay.

We are taking round of the point a along γ k times that means γ encircles the point a k times in the counterclockwise direction and the further we notice that integral over

$\int_{\gamma} \frac{dz}{z-a} = 2\pi k$ why because integral over γ of $\frac{dz}{z-a}$ will be = integral over 0 to $2\pi k$ and $dz = re^{it} i dt$ which is re^{it} to the power i . So we will get $2\pi k$ okay.

Or we can say $\frac{1}{2\pi i} \int_{\gamma} \frac{dz}{z-a} = k$ okay. So hence if γ encircles the point a k times in the counterclockwise direction then we are getting the value as k , but if γ encircles the point a k times in the clockwise direction okay, in the opposite direction then we will have the value as $-k$ okay. So here we are considering a particular case where γ is the circle with center at the point a and the radius of γ is r .

(Refer Slide Time: 03:38)

Thus we note that in either case,

$$\frac{1}{2\pi i} \int_{\gamma} \frac{dz}{z-a}$$

is an integer.

Therefore, intuitively we can say that the winding number is the number of times γ wraps around ' a ' in counter-clockwise direction.

Definition 1 (Winding number)

Let γ be a closed contour in C such that $a \in C \setminus \gamma$. Then the index (or winding number) of γ about a , denoted by $n(\gamma; a)$ is given by the integral

$$n(\gamma; a) = \frac{1}{2\pi i} \int_{\gamma} \frac{dz}{z-a}.$$

In the general case okay where γ is any closed contour okay we can intuitively say that the winding number is the number of times so this actually give $\frac{1}{2\pi i}$ okay. Integral over γ of $\frac{dz}{z-a}$ whether we are moving anticlockwise or we are moving clockwise it is an integer. In the anticlockwise direction we are getting k in the clockwise direction we are getting $-k$, so it is always an integer.

Now intuitively we can say that the binding number is the number of times γ wraps around the point a in counterclockwise direction. Now we have the analytic definition here of the winding number, let γ be any closed contour in C , such that a does not belong to γ , that is a belongs to $C - \gamma$ then the index or binding number of γ about a denoted by $n(\gamma; a)$ is given by the integral $n(\gamma; a) = \frac{1}{2\pi i} \int_{\gamma} \frac{dz}{z-a}$.

So this n represents the index of the closed contour γ about the point a or the bounding number about the point a , bounding number or γ .

(Refer Slide Time: 04:51)

Now you can see here this is our point P and we are moving like this. Suppose we start from here okay. So we are moving anticlockwise okay about the point P okay twice okay. So this means that n , if this is your curve γ okay, here we are taking it as curve C , so $n(C; P) = 2$. We are moving about this point P in the anticlockwise direction okay twice. So index number of C okay about the point a , here we have P , about the point $P = 2$ or winding number $= 2$.

(Refer Slide Time: 05:51)

Figure : Fig.2

Now let us look at this point here, this is your origin suppose okay, then we are moving twice in the clockwise direction okay about the origin. So index number is -2 here, here again we

are moving about this point origin let us say, so we are moving clockwise okay, once and therefore the index number is -1, here we are moving anticlockwise but the point this 0 is outside. We are not moving in the anticlockwise direction about the point 0 okay.

It is lying outside, so index number is 0 and here we are moving about the point 0 in the anticlockwise direction 1, so binding number is 1, here we are moving about this point 0 twice in the anticlockwise direction. So winding number is 2. Here we are moving 3 times okay in the anticlockwise direction about this point, let us say origin, so the binding number is 3.

(Refer Slide Time: 06:49)

Theorem 2

For every closed contour $\gamma \in \mathbb{C}$ and $a \in \mathbb{C} \setminus \gamma$, $n(\gamma; a)$ is an integer.

Proof:

Let $\gamma : [0, 1] \rightarrow \mathbb{C}$, then $\gamma(0) = \gamma(1)$. Let us define the function

$$g(t) = \int_0^t \frac{\gamma'(s)}{\gamma(s) - a} ds \quad (1)$$

Then, clearly $g(0) = 0$ and g is continuous on $[0, 1]$. Moreover, for $t \in [0, 1]$

$$g'(t) = \frac{\gamma'(t)}{\gamma(t) - a}$$

at every point of continuity of $\gamma'(t)$.

NPTEL ONLINE CERTIFICATION COURSE
6

Okay now let us show that for every closed curve, we have earlier seen that in the case of gamma being circle, mod of $z - a = r$ okay and gamma a is an integer okay. When we take anticlockwise direction it is positive integer, when we take clockwise direction it is a negative integer. Now let us prove that for every simple closed curve okay gamma in C where a is any complex number in C – gamma, that means it does not belong to gamma okay.

And gamma is an integral, so let us start with the proof, let gamma be a mapping from $0, 1 \rightarrow \mathbb{C}$ then since gamma is a closed curve okay gamma 0 will be = gamma 1 okay. The value of gamma will co-inside at 0 and 1. Now let us define the function $g(t) = \int_0^t \frac{\gamma'(s)}{\gamma(s) - a} ds$, then you can see that $g(0) = 0$, because when you put $t = 0$ the lower and upper limit of this integral will be 0.

So $g_0 = 0$ and furthermore from this definition of g we can see that g is continuous on $[0, 1]$ interval. Further for t belonging to $[0, 1]$ on interval $g'(t) = \gamma'(t)/\gamma(t) - a$ okay by differentiation under the sign of integration. Now at every point of continuity of γ .

(Refer Slide Time: 08:21)

Proof cont...

Let $h(t) = (\gamma(t) - a)e^{-g(t)}$ $h'(t) = \left[\gamma'(t)e^{-g(t)} + (\gamma(t) - a)e^{-g(t)}(-g'(t)) \right]$

then $h'(t) = 0$, $= \left[\gamma'(t)e^{-g(t)} - \gamma'(t)e^{-g(t)} \right] = 0$

at every point of continuity of $\gamma'(t)$.

Since γ is piecewise smooth, $h'(t) = 0$ fails to hold only at a finite number of points in $[0, 1]$. By the continuity of h , $h(t) = a$ constant say 'c' in $[0, 1]$.

In particular $h(0) = h(1)$. Since $\gamma(0) = \gamma(1)$, we obtain $h(0) = (\gamma(0) - a)e^{-g(0)}$
 $h(1) = (\gamma(1) - a)e^{-g(1)}$
 Since $\gamma(0) = \gamma(1)$ and $g(0) = 0$,
 we get from $h(0) = h(1)$
 $e^{-g(1)} = 1$

$\Rightarrow g(1) = 2\pi i k$ for some k . $\Rightarrow g(1) = 2\pi i k$

Hence (1) implies $k = \frac{1}{2\pi i} \int_0^1 \frac{\gamma'(s)}{\gamma(s) - a} ds$

Let us define function $h(t) = \gamma(t) - a e^{-g(t)}$ okay. Then $h'(t)$ let us find $h'(t)$ here, $h'(t) =$ it is product of 2 functions of t , so $\gamma'(t) * e^{-g(t)} + \gamma(t) - a * e^{-g(t)} * -g'(t)$ okay, and let us go to the previous slide $g'(t) = \gamma'(t)/\gamma(t) - a$. So $g'(t) * \gamma(t) - a = \gamma'(t)$ okay. So we have $g'(t) * \gamma(t) - a = \gamma'(t)$.

So this will be $= \gamma'(t) e^{-g(t)} - \gamma(t) - a e^{-g(t)}$ okay, so this cancels with this and we get 0. So $h'(t) = 0$ at every point of continuity of γ . Now since γ is piecewise smooth $h'(t) = 0$ fails to hold only at a finite number of points in $[0, 1]$ interval. By the continuity of h therefore $h(t)$ is a constant, let us say C okay, some constant C in the interval $[0, 1]$.

In particular, we can say that h_0 is same as h_1 okay. Now $h_0 = \gamma(0) - a e^{-g_0}$ okay, okay and $h_1 = \gamma(1) - a e^{-g_1}$ okay. We know that $\gamma(0) = \gamma(1)$ okay and $g_0 = 0$ okay, so what do we get. Since $\gamma(0) = \gamma(1)$ and $g_0 = 0$, we get h_1 here okay. So we get from $h_0 = h_1$, what we get, $\gamma(0) - a$ will cancel with $\gamma(1) - a$ okay. What we will get e^{-g_0} .

E to the power $-g_0$ means 1 okay, so e to the power $-g_1 = 1$ okay, that is we get this equation and this we will mean that $g_1 = 2\pi i k$, okay for some integral k, for some integer k okay. So now what is g_1 ? Let us see $g_1 = \int_0^1 \gamma'(s)/\gamma(s) ds$, so $k = 1/2\pi i \int_0^1 \gamma'(s)/\gamma(s) ds$ okay. So $n_\gamma(a)$ where n_γ is this okay $1/2\pi i \int \gamma'(z)/\gamma(z) dz$, okay it is an integer okay we are taking γ as $\gamma(t)$ here okay or $\gamma(s)$.

(Refer Slide Time: 12:09)

Example 3

From the example

$$\frac{1}{2\pi i} \int_\gamma \frac{dz}{z-a} = k \in \mathbb{Z},$$

where $\gamma(t) = a + re^{2\pi i kt}$, we find that $n_\gamma(a) = k$ for $|z-a| < r$ and $n_\gamma(a) = 0$ for $|z-a| > r$.

Thus, the concept of winding number characterizes the interior and exterior of a closed curve γ as follows:

and

$$\text{Int}(\gamma) = \{z \notin \gamma : n_\gamma(z) \neq 0\}$$

$$\text{Ext}(\gamma) = \{z \notin \gamma : n_\gamma(z) = 0\}.$$

So from the example $1/2\pi i \int_\gamma dz$ upon $z-a = k$ where k is an integer, okay let us go back to the example with which we started, we had considered γ as a circle okay, at the point $z = a$ of radius r . So in that example we had taken γ as mod of $z-a = r$ that is γ bar given by $z = a + re^{it}$ okay. So and t was varying from 0 to $2k\pi$ okay.

So $\gamma(t)$ was $a + re^{2\pi i kt}$ okay. We find that $n_\gamma(a) = k$, so this means what, suppose this is 0. a okay, this 0. a and we are getting this circle mod of $z-a = r$ okay, then from here it follows that $n_\gamma(a)$, from this example it follow that $\gamma(a) = k$, so if z is inside this circle, mod of $z-a = r$ then and $\gamma(a) = k$, then for that means for any z inside the circle and $\gamma(a) = k$ and when z is outside okay.

So when mod of $z-a$ is $< r$ and $\gamma(a) = k$, suppose z is outside okay, it is not inside let us draw another figure, z is here suppose then and $\gamma(a) = 0$ if z lies outside okay. Mod of $z-a > r$. So thus the concept of binding number characterizes the interior and exterior of the closed curve γ s follow. For the interior of γ okay, interior of γ by interior

of gamma what do we get it is the set of all those points that do not belong to gamma, and for which $n_{\gamma}(z)$ is never 0.

Exterior of gamma is those points z which do not belong to gamma and $n_{\gamma}(z) = 0$ because you take any z outside this circle okay, then for that $n_{\gamma}(z)$ will be $= 0$. So if $n_{\gamma}(a) = k$ for $\text{mod of } z - a < r$ and $n_{\gamma}(a) = 0$ for $\text{mod of } z - a > r$, so interior of gamma is the set of all those points which do not belong to z such that $n_{\gamma}(z) \neq 0$. So we can see the interior and exterior of a closed curve by this. So this should be $n_{\gamma}(a) \neq 0$ and $n_{\gamma}(a) = 0$.

(Refer Slide Time: 15:18)

Example cont...

Further a closed curve $\gamma : [a, b] \rightarrow \mathbb{C}$ is called positively oriented if $n(\gamma; z) > 0$ for every z inside γ and is negatively oriented if $n(\gamma; z) < 0$ for every z inside γ .

Theorem 4

If γ consists of finitely many closed contours $\gamma_1, \gamma_2, \dots, \gamma_k$ in \mathbb{C} , then every $a \notin \bigcup_{i=1}^k \gamma_i$

- i) $n(\gamma; a) = n(\gamma_1; a) + n(\gamma_2; a) + \dots + n(\gamma_k; a)$
- ii) $n(-\gamma_1; a) = -n(\gamma_1; a)$

Now let us consider a closed curve gamma from a, b to \mathbb{C} , it is called positively oriented. If $n_{\gamma}(z) > 0$, for every z inside gamma and it is negatively oriented if $n_{\gamma}(z) < 0$, so we can say that if gamma is a closed curve it will be positively oriented if $n_{\gamma}(z) > 0$ for every z inside gamma and it is negatively oriented if $n_{\gamma}(z) < 0$ for every z inside gamma.

Now if gamma consists of finitely many closed contours gamma 1, gamma 2, gamma k and C then for every a which do not belong to union of gamma i okay, $n_{\gamma}(a) = n_{\gamma_1}(a) + n_{\gamma_2}(a)$ and so on and gamma k okay, that is the winding number of gamma about the point a is some of the winding numbers of the curves to gamma 1, gamma 2, gamma k about the point a .

This we can easily see from the figures here, you can see here this here the gamma consists of 2 curves gamma 1 and gamma 2, so n gamma about this point, let us say this is origin, so n gamma about the point origin is n gamma 1 about the point origin and n gamma 2 about the origin. Here n gamma about the point origin is n gamma 1, you can call it as gamma 1, this as gamma 2, this as gamma 3 okay and similarly for the other curves okay.

And this identity tells us that the binding number of n okay about the curve – gamma 1, so gamma 1 we are taking in the anticlockwise direction – gamma 1 means we are going in the clockwise direction. So binding number about the point a of the curve – gamma 1 okay is same as – of binding number of gamma 1 about the point a okay. So this is made clear.

(Refer Slide Time: 17:15)

Maximum modulus principle

It is a powerful tool to obtain an explicit estimate for the size of the absolute value of an analytic function. Since \mathbb{C} is not an ordered field, we consider the maximum and minimum values of the modulus of the complex function f .

For example, consider $f(z) = e^z$.

then $\max_{|z| \leq r} |e^z| = e^r$.

Also, consider $f(z) = \cos z$.

then $\max_{|z| \leq r} |\cos z| = \cosh r$.

At $z = r$, we get $|f(z)| = |e^z| = e^r$.

Thus $\max_{|z| \leq r} |f(z)| = e^r$.

At $z = r$, we get $|f(z)| = |\cos z| = \cosh r$.

Thus $\max_{|z| \leq r} |f(z)| = \cosh r$.

When $|z| \leq r$, $-r \leq x \leq r$.

When $|z| \leq r$, $-r \leq x \leq r$.

At $z = r$, we get $|f(z)| = |e^z| = e^r$.

Thus $\max_{|z| \leq r} |f(z)| = e^r$.

At $z = r$, we get $|f(z)| = |\cos z| = \cosh r$.

Thus $\max_{|z| \leq r} |f(z)| = \cosh r$.

10

Now let us discuss maximum modulus principle. Maximum modulus principle is the powerful tool to obtain an explicit estimate for the size of the absolute value of an analytic function. Since \mathbb{C} is not an ordered field we can consider the maximum and minimum values of the modulus of the complex function okay. So let us consider say for example $fz = e$ to the power z okay.

Then if you take the close circular disc $\text{mod } z \leq r$ okay, let us consider the closed circular disc $\text{mod of } z \leq r$, then maximum value of $\text{mod of } e$ to the power z okay this closed circular disc, $\text{mod of } z \leq r$ is e to the power r and it is attained at the point $z = r$, this okay. Here $z = r$, so it is attained on the boundary of the closed circular disc. Okay now let us see how we get this maximum value, $\text{mod of } fz = \text{mod of } e$ to the power z which is $= \text{mod of } e$ to the power $x + i y$.

So this is mod of e to the power $x * e$ to the power $i y$ and then mod of e to the power $x * \text{mod of } e \text{ to the power } i y$ gives us, e to the power x is always positive because x is real. So this is e to the power x and mod of e to the power $i y$ is mod of $\cos/+ i \sin/$ so that is $= 1$. So mod of $fz = e$ to the power x . Now for this circle mod of $z = r$ okay, x varies from $-r$ to $+r$ okay.

So when mod of z is $\leq r$, $-r$ is $\leq x$, $\leq r$ okay. So and e to the power x is an increasing function of x , so this is $\leq e$ to the power x or whenever $-r$ is $\leq x$, $\leq r$. So this is valid for all z okay, such that mod of z is $\leq r$. So maximum value of mod of fz when mod of z is $\leq r$ is $\leq e$ to the power r . Now let us show that there is a point satisfying mod of $z \leq r$ where mod of $fz =$ exactly e to the power r .

And that is the point $z = r$. So at $z = r$ we get mod of $fz =$ mod of e to the power $z = e$ to the power r . Mod of e to the power r is e to the power r because e to the power r is always positive. So there is a point $z = r$ where mod of fz becomes e to the power r . So maximum value of mod of fz , when mod of z is $\leq r$ okay, is definitely $>$ mod of fr , okay and mod of fr is e to the power r .

So what do we notice, maximum value of mod of fz , when mod of z is $\leq e$ to the power r and here maximum value of mod of fz when mod of z is $\leq r$ is $> r = e$ to the power r and thus maximum value of mod of fz when mod of z is $\leq r$ is e to the power r and we can see that e to the power r , the maximum value of mod of fz is attained on the boundary of mod of $z \leq r$.

Now if you take $fz = \cos z$ okay, then $\cos z = e$ to the power $iz + e$ to the power $-iz/2$ okay. So mod of $\cos z$ is $\leq \text{mod of } e \text{ to the power } iz + \text{mod of } e \text{ to the power } -iz/2$ and this is $= \text{mod of } e \text{ to the power } i \text{ times } x + iy + \text{mod of } e \text{ to the power } -i \text{ times } x + iy/2$. So here what do we get, this is e to the power $ix * e$ to the power $i \text{ square } y$, $i \text{ square } y$ means $-y$, mod of e to the power $ix = 1$ and so this is e to the power $-y$.

And here we get e to the power $-ix$ whose modulus is 1 and then we get e to the power $-i \text{ square } y$ which is e to the power y . So e to the power $-y + e$ to the power $y/2$ which is \cos hyperbolic y , okay, and \cos hyperbolic y is an increasing function of y and here what is

happening is that for $\text{mod of } z \leq r$, y also varies from $-r$ to $+r$ okay. So $-r \leq y \leq r$. So this is $\leq \cos \text{hyperbolic } r$ okay.

You can easily see that $\cos \text{hyperbolic } y$ is an increasing function because $\cos \text{hyperbolic } y$ is e to the power $y + e$ to the power $-y/2$ okay and when you differentiate $\cos \text{hyperbolic } y$ you get e to the power $y - e$ to the power $-y/2$ which is nothing but e to the power $2y - 1/2$, this okay, $\cos \text{hyperbolic } y$ is this function okay, it is an even function right. So at $y = 0$ $\cos \text{hyperbolic } y$ takes value 1, so it is like this okay.

And so it is a symmetric function about this y okay, $\cos \text{hyperbolic } -y = \cos \text{hyperbolic } y$. So when we consider $\cos \text{hyperbolic } y$, we need to consider the values of y , positive values of y , for the indicative values of y , its graph is the same because it is symmetric. So it takes the same values as it takes for positive values of y . so e to the power $2\pi - 1$ over 2 e to the power y is always ≥ 0 when y is ≥ 0 okay.

So it is an increasing function of y , so e to the power $-y + e$ to the power $y/2$ is greater than, is an increasing function for all values of y . So $\cos \text{hyperbolic } y \leq \cos \text{hyperbolic } r$. So what we have maximum value of $\text{mod of } \cos z$ when $\text{mod } z$ is $\leq r$ is $\leq \cos \text{hyperbolic } r$ and then what do you do, you take. Now you want to show that maximum value of $\text{mod of } \cos z$ when $\text{mod } z$ is $\leq r$ is $\geq \cos \text{hyperbolic } r$ okay.

So for that you need to consider $z = ir$, if you take $z = ir$ then $\cos ir = e$ to the power $-r + e$ to the power $r/2$ that is $\cos \text{hyperbolic } r$. You can also consider $z = -ir$. If $z = -ir$ then also $\cos z = \cos ir = e$ to the power i square r , so e to the power $-r + e$ to the power $r/2$ and both these points $-ir$ okay and ir okay. Whether this point you take or you take this point, for both the points $\cos z$ takes the maximum value e to the power $r + e$ to the power $-r/2$ and these are the points here. This is $z = ir$, this is $z = -ir$ okay.

So maximum value of $\text{mod of } \cos z$ for $\text{mod } z \leq r$, $\text{mod of } z \leq r$ will always be \geq the value of $\text{mod of } \cos z$ at $z = ir$ or $z = -ir$ which is $\cos \text{hyperbolic } r$. So maximum value of $\text{mod of } \cos z$ when $\text{mod } z$ is $\leq r = \cos \text{hyperbolic } r$ okay.

(Refer Slide Time: 26:14)

Theorem 5 (Maximum modulus theorem)

Let D be a bounded domain and suppose that $f(z)$ is analytic and non-constant in D and continuous on the boundary of D . Then the absolute value $|f(z)|$ attains its maximum value on the boundary of D .

Proof:

Since $f(z)$ is continuous inside D and on the boundary of D , it follows that $|f(z)|$ assumes its maximum value M for some z inside or on the boundary of D . Let us suppose that $|f(z)|$ attains its maximum value at an interior point a' of D i.e.

$|f(a)| = M$. Since $f(z)$ is not a constant, $|f(z)|$ is also not a constant.

$$|f(a)| = M = \max_{z \in D} |f(z)|$$

Consequently, we can find a circle C of radius r with center at a' such that the interior of C is in D and $|f(z)|$ is smaller than M at some point b of C . Since $|f(z)|$ is continuous, it will be smaller than M on an arc C_1 of C which contains b , say, $|f(z)| \leq M - \epsilon$ ($\epsilon > 0$) $\forall z$ on C_1 .

So we go to now this maximum modulus theorem, let D be a bounded domain and suppose that fz is analytic and non-constant in D and continuous on the boundary of D , then the absolute value of mod of fz attains its maximum value on the boundary of D , as we have seen in the case of $fz = e$ to the power z and $fz = \cos z$.

Then their maximum values in the case of e to the power z is e to the power r it is attained at the boundary point $z = r$ while in the case of $\cos z$ the maximum value of mod of $\cos z$ is attained at the points $z = ir$ and $z = -ir$ which lie on the boundary of mod of $z \leq r$. So let us prove this, since fz is continuous inside D and on the boundary of D , on the boundary of D we are given that it is continuous inside D , it follows from the analyticity okay.

So since fz is continuous inside D and on the boundary of D it follows that mod of fz must assume its maximum value for some z inside r on the boundary of D , by the continuity. Now let mod of fz attains its maximum value at an interior point okay. So we are assuming that, actually have to prove that it assumes its maximum value on the boundary of D , but here we want to prove it by contradiction method.

So we are assuming that, it assumes its maximum value at a point interior to D okay and that point let us say be a . So that is mod of $fa = M$. Since fz is not constant we are assuming that fz is non-constant okay, so mod of fz is also not constant okay and consequently we can find a circle C of radius r , so let us say suppose this is your domain okay D , so a is a point here. we can construct a circle.

Now mod of f_a we are assuming to be = maximum value M , M is the maximum value of mod of f_z for all z in D okay. So maximum value of mod of f_z we are assuming that, it occurs at the point a okay. So mod of $f_a = M$ and since f_z is not constant mod of f_z also will not be constant so we can find a circle c , let us construct circle c here okay, constant circle c of radius r .

Let us say this radius is r okay, a bit center at a such that the interior of C is in D , the curve lies C , curve lies completely inside D and mod of f_z is smaller than M at some point b of C , okay, so there is some point b on the curve C such that mod of f_z is smaller than M because M this is the maximum value and it is not constant, so it will have to happen that there will be some point on the curve C at which mod of f_z is smaller than M .

So since mod of f_z is continuous it will be smaller than M , f_z is continuous so mod of f_z is continuous. So there will be an arc of the circle C okay, let us call that arc as C_1 , which contains B and such that mod of f_z is $\leq M - \epsilon$ for all z on C_1 . So there will be some part of this curve C , which we can call as C_1 which contains the point B and for which mod of f_z is $\leq M - \epsilon$ okay.

(Refer Slide Time: 29:51)

Figure : Fig.3

So this is the curve C okay, this is the curve C and we have taken this arc okay, this is my point B okay, $z = b$ here okay, and this is z_0 , z_0 is a actually, z_0 is a we are taking the curve C , we center at a . So z_0 in this figure is actually a and the arc C_1 of the circle C contains the point B and mod of f_z is $\leq M - \epsilon$ okay, where ϵ is > 0 okay. For all z on C_1 okay.

So let us say C_1 has length 1, the complementary arc C_2 okay, the complementary arc C_2 then will have length $2\pi r - l_1$ okay.

(Refer Slide Time: 30:46)

Proof cont...

If C_1 has length l_1 , the complementary arc C_2 has the length $2\pi r - l_1$ ✓

$$\begin{aligned}
 M &= |f(a)| = \frac{1}{2\pi} \left| \int_C \frac{f(z)}{z-a} dz \right| && f(a) = \frac{1}{2\pi i} \int_C \frac{f(z)}{z-a} dz \\
 &\leq \frac{1}{2\pi} \left[\left| \int_{C_1} \frac{f(z)}{z-a} dz \right| + \left| \int_{C_2} \frac{f(z)}{z-a} dz \right| \right] && |f(z)| = \frac{1}{2\pi i} \int_C \frac{f(z)}{z-a} dz \\
 &< \frac{1}{2\pi} \left[\frac{(M-\epsilon)}{r} l_1 + \frac{M}{r} (2\pi r - l_1) \right] && \leq \frac{1}{2\pi} \left(\frac{M-\epsilon}{r} l_1 + \frac{M}{r} (2\pi r - l_1) \right) \\
 &= M - \frac{\epsilon l_1}{2\pi r} < M, && \frac{M l_1}{r} - \frac{\epsilon l_1}{r} + 2\pi M - \frac{M l_1}{r}
 \end{aligned}$$

$\frac{1}{2\pi} \left(\frac{2\pi M - \epsilon l_1}{r} \right)$
 $= M - \frac{\epsilon l_1}{2\pi r}$

which is impossible and hence $|f(z)|$ attains its maximum value on the boundary of D .

So $M = \text{mod of } f(a)$ then $< f$ because $f(a)$ is given by Cauchy's integral formula $\frac{1}{2\pi i} \int_C \frac{f(z)}{z-a} dz$ okay. So mod of $f(a)$ will be \leq this will imply mod of $f(a)$, this is $= \frac{1}{2\pi i} \int_C \frac{f(z)}{z-a} dz$ mod of integral over C $fz dz/z - a$ here. Okay so and then we can break it into 2 parts, this is $\leq \frac{1}{2\pi i} \int_{C_1} \frac{fz dz}{z-a} + \int_{C_2} \frac{fz dz}{z-a}$ okay. So with the integrant being $fz/z-a$ okay. So integral over C_1 $fz/z-a$ + integral over C_2 $fz/z-a$ okay, like this.

So $\frac{1}{2\pi i}$, now the mod of $fz/z-a$ on the curve C_1 , okay, on the curve C_1 is $\leq M - \epsilon$ over r , because the circle C is having center at a and radius r . So mod of $z-a = r$ on C_1 okay and on C_1 mod of fz is $\leq M - \epsilon$. So $M - \epsilon / r * \text{length of } C_1$. So length of C_1 is l_1 and then here mod of fz is $\leq M$ okay, because M is the maximum value okay. So M and then mod of $z-a = r$ length of C_2 is $2\pi r - l_1$.

So when you simplify this what you get is $M - \epsilon * \frac{l_1}{2\pi r}$ okay. Because this is if you multiply what you get $M l_1$ okay $/ r - \epsilon l_1 / r$ okay and here what do we get here, $M 2\pi M$ okay $- M l_1 / r$, so this cancels with this okay and we get $\frac{1}{2\pi} \times - \epsilon l_1 / r$. So this is $M - \epsilon l_1 / 2\pi r$. Now definitely this quantity is $< M$ because $\epsilon l_1 / 2\pi r$ is a positive quantity. So what we get M is $< M$ which okay, which is impossible and therefore mod of attains it is maximum value on the boundary of D .

Theorem 6 (Minimum modulus theorem)

Suppose that $f(z)$ is analytic in a bounded domain D and continuous on the boundary of D . If $f(z) \neq 0$ in D , then $|f(z)|$ attains its minimum value on the boundary of D .

Proof.

If $f(z) \neq 0$ in D , then $\frac{1}{f(z)}$ is analytic in D , hence $\frac{1}{|f(z)|}$ assumes its maximum value on the boundary of D and so $|f(z)|$ attains its minimum value on the boundary of D . \square

o

Now we can easily prove the minimum modulus theorem from the maximum modulus theorem. Suppose that fz is analytic in a bounded domain D and continuous on the boundary of D if fz is not equal to 0 in D then $\text{mod of } fz$ attains its minimum value on the boundary of D . So suppose that if fz is not equal to 0 and D then let us suppose that, we consider the function $1/fz$ okay.

So then $1/fz$ is analytic in D and hence by the maximum modulus theorem $1/fz$ will assume its maximum value on the boundary of D and when $1/fz$ is maximum on the boundary of D $\text{mod of } fz$ is attaining its minimum value on the boundary of D .

Example 7

Let

$$f(z) = z^2 - 3z + 2.$$

Then

$$\max_{|z| \leq 1} |f(z)| = 6, \text{ at } z = -1.$$

$|f(z)| = |z^2 - 3z + 2| \leq |z|^2 + 3|z| + 2 \leq 1 + 3 + 2 = 6$, when $|z| \leq 1$
 $\max_{|z| \leq 1} |f(z)| \leq 6$
 $\max_{|z| \leq 1} |f(z)| \geq |f(-1)| = (-1)^2 - 3(-1) + 2 = 6$
Thus, $\max_{|z| \leq 1} |f(z)| = 6$.

Let us say for example $fz = z^2 - 3z + 2$ okay. We need to find the maximum value of fz okay, $\text{mod of } fz$, when $\text{mod of } z$ is ≤ 1 . So $\text{mod of } fz = \text{mod of } z^2 - 3z + 2$ which is

$\leq \text{mod of } z^2 + 3 \text{ times mod of } z + 2$ okay and which is $\leq 1 + 3 + 2$ okay, whenever $\text{mod of } z$ is ≤ 1 . So this is $= 6$ okay. So maximum of $\text{mod of } fz$, when $\text{mod of } z$ is ≤ 1 is ≤ 6 .

Now we notice that at $z = 1$, $z = -1$ okay $z = -1$ fz becomes equal to 6. So maximum value of $\text{mod of } fz$ when $\text{mod of } z$ is ≤ 1 is greater than or $= \text{mod of } f - 1$ okay. Because -1 lies on the unit circle, okay, this is $\text{mod of } z = 1$, so this is -1 here okay. So when you take $z = -1$ it satisfies the inequality $\text{mod of } z \leq 1$ and so the maximum value of $\text{mod of } fz$ when $\text{mod } z \leq 1$ will always be greater than $\text{mod of } f - 1$, but this gives you $-1^2 - 3 * -1 + 2$ which is $= 6$.

So maximum value of $\text{mod of } z$ when $\text{mod } z \leq 1$ is ≥ 6 and thus this is $= 6$ okay. This is $= 6$ which is attained, maximum value is attained at the boundary, that is at the point $z = -1$ of $\text{mod } z = 1$ okay. With that I would like to end my lecture. Thank you very much for your attention.
