Lecture – 12
Sequences and Series

Hello friends welcome to my lecture on sequences and series of complex functions. Let us consider an infinite series of functions of a complex variable. We shall see that most of the definitions and theorems obtained for infinite series of real terms can be applied with little or no change to the series whose terms are complex. Let us consider a sequence f_n and z , $n = 1, 2, 3$ and so on be a sequence of functions defined on a set D of complex numbers.

Then consider the series $\sum_{n=1}^{\infty} f_n(z) = f_1(z) + f_2(z) + \dots + f_n(z) + \dots$

(Refer Slide Time: 01:03)

We shall now consider infinite series of functions of a complex variable. We shall see that most of the definitions and theorems obtained for infinite series of real terms can be applied with little or no change to the series whose terms are complex.

Let $\{f_n(z)\}$, $n = 1, 2, \dots$ be a sequence of functions defined on a set D of complex numbers. Then consider the series

$$\sum_{n=1}^{\infty} f_n(z) = f_1(z) + f_2(z) + \dots + f_n(z) + \dots \quad (1)$$

The sum of first n^{th} terms

$$S_n(z) = \sum_{m=1}^n f_m(z).$$

is called the n^{th} partial sum of the series.

Then the sum of the first n terms of the series is given by the function $S_n(z)$. $S_n(z) = \sum_{m=1}^n f_m(z)$ and it is called the n^{th} partial sum of the series.

(Refer Slide Time: 01:22)

The series is called convergent on the set D if

$$\lim_{n \rightarrow \infty} S_n(z) = f(z) \quad (2)$$

exists for every z in D . The function $f(z)$ is called the sum of the series at the point z in the complex plane. By definition of limit, the series

$$\sum_{m=1}^{\infty} f_m(z) = f_1(z) + f_2(z) + \dots + f_n(z) + \dots$$

converges to $f(z)$, if for a given $\epsilon > 0$ \exists a positive integer $n_0(\epsilon, z)$ such that

$$|S_n(z) - f(z)| < \epsilon, \forall n > n_0. \quad (3)$$

The series is said to be convergent on the set D if limit n tends to infinity $S_n z = fz$ exists for every z in D . The function fz is then called the sum of the series at the point z in the complex plane by definition of limit the series $\sigma m = 1$ to infinity $f m z = f1 z + f2 z$ and so on $f n z$ converges to fz for a given $\epsilon > 0$, we can find positive integer n_0 depending on ϵ and z , such that $\text{mod of } S_n z - fz$ is $< \epsilon$ for all n greater than n_0 .

You can see that the definition is here is same as we have in the case of series of functions of a real variable.

(Refer Slide Time: 02:10)

The function $f_n(z)$ is called the general term or n^{th} term of the series.

From (3) it follows that if the series (1) is convergent and has the sum $f(z)$ then at the point z ,

$$|R_n(z)| = |f_{n+1}(z) + f_{n+2}(z) + \dots|$$

must tend to zero as $n \rightarrow \infty$. The term $R_n(z)$ is called the remainder of the series after n terms.

If limit in (2) does not exist for some $z = z_0$, the series is said to be divergent at $z = z_0$. If the series is divergent for every z in D , it is called a divergent series in D .

The series (1) is called absolutely convergent at a point z in D if $\sum_{m=1}^{\infty} |f_m(z)|$ is convergent. The series in (1) is called conditionally convergent if it is convergent but not absolutely convergent.

$$|S_n(z) - f(z)| = \left| \sum_{m=1}^n f_m(z) - \sum_{m=1}^{\infty} f_m(z) \right|$$

$$|R_n(z)| = |f_{n+1}(z) + f_{n+2}(z) + \dots| < \epsilon, \forall n \geq n_0(\epsilon, z)$$

Now the function $f_n z$ here is called the general term or the n^{th} term of the series $\sigma f m z$ where $m = 1$ to infinity. Now from 3 it follows that let us look at 3 from this inequality it follows that $\text{mod of } S_n z - fz$ means, $S_n z$ is the sum of the first terms of the series okay, so

$S_n z - f z$ means you will have $S_n z - f z = f_{n+1} z + f_{n+2} z$ and so on, first n terms from the sum function $f z$ will be removed and we will have the terms $f_{n+1} z$ and so on, $f_{n+2} z$ and so on, which we denote by $R_n z$.

$R_n z$ is called the remainder of the series after n terms. So $\text{mod of } R_n z = \text{mod of } f_{n+1} z + f_{n+2} z$ and so on. Modulus of this quantity, that is this must go to 0 as n goes to infinity. Mod of we can see, $\text{mod of } S_n z - f z$. This is $= \text{mod of } \sum_{m=1}^{\infty} f_m z - \sum_{m=1}^n f_m z$, this is n , here $M = 1$ to infinity $f_m z$. So this is $= \text{mod of } f_{n+1} z, f_{n+2} z$ and so on okay. So $\text{mod of } R_n z - f z$ is said to be the sum remainder after n terms of the series and we denoted by $R_n z$.

So $R_n z \text{ mod of } R_n z = \text{this}$, this should be $< \epsilon$ for all $n \geq n_0$ depending on ϵ $n z$ and this means that $\text{mod of } R_n z$ should go to 0 as n goes to infinity $R_n z$ is called the remainder of the series after n terms. Now if limit in 2, this is your 2 okay, if limit in 2 exist, if the limit in 2 does not exist for some $z = z_0$ then we say that the series is divergent at $z = z_0$ and if this occurs for every z in D that is the series is divergent for every z in D we call it a divergent series in D .

Now the series 1 is called absolutely convergent, we call this series, this series 1 to the absolutely convergent, if the corresponding series of absolute value is of the sequence functions $f_m z$ is convergent. So $\sum_{m=1}^{\infty} \text{mod of } f_m z$ if it is convergent we say that the given series is absolutely convergent at the point z . Now the series given by equation 1, this series is called conditionally convergent if it is convergent but not absolutely convergent.

(Refer Slide Time: 05:20)

Since the series $\sum_{n=1}^{\infty} |f_n(z)|$ is a series of positive real terms, the criteria for convergence for a series of real positive terms can be applied to this series. Thus, if $\sum_{n=1}^{\infty} |f_n(z)|$ is absolutely convergent then

$$R_n(z) = |f_{n+1}(z)| + |f_{n+2}(z)| + \dots \rightarrow 0 \text{ as } n \rightarrow \infty \quad \checkmark$$

$$\Rightarrow f_{n+1}(z) + f_{n+2}(z) + \dots \rightarrow 0 \text{ as } n \rightarrow \infty$$

$$\Rightarrow \sum_{n=1}^{\infty} f_n(z) \text{ is convergent.}$$

$\sum_{n=1}^{\infty} |f_n(z)|$
 $|f_{n+1}(z) + f_{n+2}(z) + \dots| \rightarrow 0$

Thus absolute convergence implies convergence but converse is not true.

Since the series $\sum_{n=1}^{\infty} \text{mod of } f_n z$ is the series of positive real terms okay, the criteria for convergence for a series of real positive terms can be applied to this series. So if $\sum_{n=1}^{\infty} \text{mod of } f_n z$ is absolutely convergent it means that $\sum_{n=1}^{\infty} \text{mod of } f_n z$, these are convergent series okay and therefore the remainder after n terms of this series r and z will be $\text{mod of } f_{n+1} z$, $\text{mod of } f_{n+2} z$ and so on.

So if the series is convergent then the remainder after n terms of this series r and z must go to 0 as n goes to infinity. So when $R_n z$ goes to 0 then goes to infinity and $R_n z$ consist of the absolute values of $f_{n+1} z$, $f_{n+2} z$ and so on then it follows that $f_{n+1} z$, $f_{n+2} z$ and so on that also goes to 0 because $\text{mod of } f_{n+1} z$, $\text{mod of } f_{n+1} z + f_{n+2} z$ and so on, okay, so when $f_{n+1} z$, $\text{mod of } f_{n+1} z$, $\text{mod of } f_{n+2} z$ and so on goes to 0 then this will also go to 0.

Okay, so we will have $\sum_{n=1}^{\infty} \text{mod of } f_n z$ is convergent and therefore absolute convergence implies convergence, but the converse is not true. We shall see an example on this fact.

(Refer Slide Time: 06:53)

For example, consider the series

$$\sum_{n=1}^{\infty} \frac{(-1)^{n-1} z^n}{n},$$

At $z=1$, we get
 $\sum_{n=1}^{\infty} \frac{(-1)^{n-1}}{n} = 1 - \frac{1}{2} + \frac{1}{3} - \frac{1}{4} + \dots$
 By Leibniz's test
 it is convergent

then this series is convergent for $z = 1$ but does not converge absolutely for $z = 1$.
 The terms of an absolutely convergent series can be arranged in any order and all such rearranged series converge to the same sum. Further, the sum, difference and product of absolutely convergent series is convergent.

Note that these are not true for conditionally convergent series.

At $z=1$, the given series
 is conditionally
 convergent

At $z=1$, then
 series is $\sum_{n=1}^{\infty} \frac{1}{n}$ divergent series

$$\sum_{n=1}^{\infty} \left| \frac{(-1)^{n-1} z^n}{n} \right|$$

$$= \sum_{n=1}^{\infty} \frac{|z|^n}{n}$$

For example, let us consider the series $\sum_{n=1}^{\infty} \frac{(-1)^{n-1} z^n}{n}$. We can see that this series is convergent for $z = 1$, because at $z = 1$ we get $\sum_{n=1}^{\infty} \frac{(-1)^{n-1}}{n}$, which is $1 - \frac{1}{2} + \frac{1}{3} - \frac{1}{4} + \dots$ and so on, which is an alternating series and by Liouville's real test we know that this series is convergent, okay so at $z = 1$ this series is convergent, but if you take the absolute value of each term that is you consider $\sum_{n=1}^{\infty} \frac{1}{n}$, mod of -1 to the power $n-1$ z to the power n/n okay.

Then you get $\sum_{n=1}^{\infty} \frac{z^n}{n}$, mod of z to the power n/n and at $z = 1$ this series is harmonic series $\sum_{n=1}^{\infty} \frac{1}{n}$, which is known to be a divergent series and therefore at $z = 1$ this series is conditionally convergent okay. So at $z = 1$ the given series is convergent but not absolutely convergent so it is the given series is conditionally convergent.

So this series is convergent but does not converge absolutely for $z = 1$. Now the terms of an absolutely convergent series can be arranged in any order and all such rearranged series converge to the same sum, further the sum difference and product of absolutely convergent series is convergent. Now these results are not true in the case of a conditionally convergent series.

(Refer Slide Time: 09:30)

Cauchy's convergence criterion holds for series of complex numbers. Thus, a necessary and sufficient condition for the series (1) to be convergent is that for a given $\epsilon > 0 \exists$ a positive integer n_0 such that

$$|S_{n+p}(z) - S_n(z)| < \epsilon, \quad \forall n > n_0 \text{ and } p = 1, 2, \dots$$

$$\sum_{n=1}^{\infty} f_n(z)$$

Since

$$|S_{n+1}(z) - S_n(z)| = |f_n(z)|,$$

it follows that a necessary condition for the convergence of the series $\sum_{n=1}^{\infty} f_n(z)$ for any fixed z is

$$\lim_{n \rightarrow \infty} f_n(z) = 0$$

but the condition is not sufficient.

Now Cauchy's convergence criterion holds for series of complex numbers. So a necessary and sufficient condition for the series $\sum_{n=1}^{\infty} f_n(z)$ to be convergent is that for a given $\epsilon > 0$, we can find positive integral n_0 such that $\text{mod of } S_{n+p} - S_n$ is $< \epsilon$ for all $n > n_0$ and for a very $p = 1, 2$ and so on. Now if you put $p=1$ here then $\text{mod of } S_{n+1} - S_n$ is $= \text{mod of } f_n$.

Because S_{n+1} is the sum of the first $n+1$ terms of the series and S_n is the sum of the first n terms of the series. So $\text{mod of } S_{n+1} - S_n$ will be $= \text{mod of } f_n$ and this is $< \epsilon$ for all n greater than n_0 , so this means that f_n must tend to 0 as n goes to infinity. So a necessary condition for the convergence of the series $\sum_{n=1}^{\infty} f_n(z)$ is that the n th term of the series must go to 0 as n goes to infinity but this condition is not sufficient.

(Refer Slide Time: 10:48)

Again, let us consider the series

$$\sum_{n=1}^{\infty} \frac{(-1)^{n-1} z^{n-1}}{n}.$$

At $z = -1$, we get

$$\sum_{n=1}^{\infty} \frac{(-1)^{2(n-1)}}{n} = \sum_{n=1}^{\infty} \frac{1}{n}$$

$$f_n(z) = \frac{(-1)^{n-1} z^{n-1}}{n}$$

$$\Rightarrow f_n(-1) = \frac{1}{n} \rightarrow 0, \text{ as } n \rightarrow \infty$$

Note that for $z = -1$

$$f_n(z) = \frac{1}{n} \rightarrow 0, \text{ as } n \rightarrow \infty$$

but the series

$$\sum_{n=1}^{\infty} f_n(-1) = \sum_{n=1}^{\infty} \left(\frac{1}{n} \right)$$

is a divergent series.

the series $\sum_{n=1}^{\infty} f_n(-1) = \sum_{n=1}^{\infty} \frac{1}{n}$ is a divergent series

Let us take an example on this. You can consider again the series $\sum_{n=1}^{\infty} \frac{1}{n}$ to the power $n-1$ z to the power $n-1$ over n , at $z = -1$ we can see $\sum_{n=1}^{\infty} \frac{1}{n}$, the series becomes at $z = -1$ we get $\sum_{n=1}^{\infty} \frac{1}{n} (-1)^{n-1}$ to the power $n-1$ $* -1$ to the power $n-1$. So -1 to the power 2 times $n-1/n$ okay, which is $= \sum_{n=1}^{\infty} \frac{1}{n}$ and so the n th term of the series.

$f_n(z)$, $f_n(z)$ was the n th term of the series, $f_n(z)$ was $= -1$ to the power $n-1$ z to the power $n-1/n$ and this gives us $f_n - 1 = 1/n$ which goes to 0 as n goes to infinity. So n th term of the series goes to 0 as n goes to infinity but what we notice is that if you put $z = -1$ in the series the series is $\sum_{n=1}^{\infty} \frac{1}{n}$ $f_n - 1 = \sum_{n=1}^{\infty} \frac{1}{n}$ and which is a divergent series.

So the series satisfies the necessary condition for convergence that is n th term of the series goes to 0 as n goes to infinity, but the series is not convergent. So it is just the necessary condition for the convergence of the series, it is not sufficient.

(Refer Slide Time: 12:38)

Theorem 1
Let $u_n(x, y)$ and $v_n(x, y)$ ($n = 1, 2, 3, \dots$) be, respectively, the real and imaginary parts of the function $f_n(z)$, of the complex variable z . Then, for any fixed z , the series

$$\sum_{n=1}^{\infty} f_n = f_1 + f_2 + \dots$$

converges to the sum $f = u + iv$, if and only if, the series of real parts and imaginary parts, i.e.

$$\sum_{n=1}^{\infty} u_n = u_1 + u_2 + \dots$$

and

$$\sum_{n=1}^{\infty} v_n = v_1 + v_2 + \dots$$

converge to the sums u and v , respectively.

Handwritten note: $f_n(z) = u_n(x, y) + i v_n(x, y)$, $n = 1, 2, 3, \dots$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 9

Now let us consider, let $U_n(x, y)$ and $V_n(x, y)$ be respectively the real and imaginary parts of the function $f_n(z)$, $f_n(z) = U_n(x, y) + i V_n(x, y)$ for all $n = 1, 2, 3$ and so on. So $U_n(x, y)$ and $V_n(x, y)$ are real and imaginary parts of the function $f_n(z)$ of the complex variable z . Then for any fixed z the series $\sum_{n=1}^{\infty} f_n(z)$, $\sum_{n=1}^{\infty} f_n(z) = f_1(z) + f_2(z) + \dots$ and so on, converges to the function f whose real part is say $U(x, y)$, imaginary part is $V(x, y)$, if and only if the series of real part $\sum_{n=1}^{\infty} U_n(x, y)$, that is $U_1(x, y) + U_2(x, y) + \dots$ and so on.

And $\sum v_n x y$ which is $v_1 x y + v_2 x y$ and so on converge to the sums U_{xy} and V_{xy} respectively.

(Refer Slide Time: 13:42)

Of all the tests of convergence for series of real terms, the ratio test and the root test are the most important. For a series of complex functions, they are as follows:

Theorem 2

Let

$$\lim_{n \rightarrow \infty} \left| \frac{f_{n+1}(z)}{f_n(z)} \right| = |r(z)|.$$

Then the series $\sum_{n=1}^{\infty} f_n(z)$ converges absolutely for those values of z for which $0 \leq |r(z)| < 1$ and diverges for those values of z for which $|r(z)| > 1$. The test fails for those values of z for which $|r(z)| = 1$.

Now of all the test for the convergence of a series of real terms. The ratio test and the root test are we know they are the most important ones, for a series of complex functions they are as follows. So let n go to infinity, limit n tends to infinity, mod of $f_{n+1} z$ over $f_n z = \text{mod of } R_z$ then the series $\sum_{n=1}^{\infty} f_n z$ converges absolutely for those values of z , for which $0 \leq \text{mod of } R_z < 1$ and diverges for those values of z for which mod of R_z is > 1 . The test fails for those values of z for which mod of R_z is $= 1$.

(Refer Slide Time: 14:27)

For example, consider the series

$$\sum_{n=1}^{\infty} \frac{(-1)^{n-1} z^n}{n}.$$

here $f_n(z) = \frac{(-1)^{n-1} z^n}{n}$

Applying the ratio test

$$\lim_{n \rightarrow \infty} \left| \frac{f_{n+1}(z)}{f_n(z)} \right| = |z| = r(z)$$

$$\left| \frac{f_{n+1}(z)}{f_n(z)} \right|$$

$$= \left| \frac{(-1)^n z^{n+1}}{n+1} \cdot \frac{n}{(-1)^{n-1} z^n} \right|$$

$$= \frac{n}{n+1} |z|$$

$$\Rightarrow \lim_{n \rightarrow \infty} \left| \frac{f_{n+1}(z)}{f_n(z)} \right| = \lim_{n \rightarrow \infty} \left(\frac{n}{n+1} \right) |z|$$

$$= |z|$$

$$\text{Thus, } r(z) = |z|$$

The given series converges
absolutely if $|z| < 1$
diverges if $|z| > 1$
The test fails if $|z| = 1$

So let us consider the series $\sum_{n=1}^{\infty} (-1)^{n-1} z^n$ to the power $n-1$ z to the power n/n , then here $f_n z = (-1)^{n-1} z^n$ to the power n/n and therefore if you find mod of f_{n+1}

z over $f_n z$, it comes out to be -1 to the power n z to the power $n+1/n+1 * n-1$ to the power $n-1 * z$ to the power n , and this is $= n/n+1 \bmod$ of z to the power $n+1/\bmod$ of z to the power n , so we get \bmod of z .

And therefore limit n tends to infinity \bmod of $f_n + 1 z/f_n z = \lim_{n \rightarrow \infty} n/n+1 * \bmod$ of z , $n/n+1$ as n goes to infinity tends to 1 , so we get \bmod of z and thus R_z here is $= \bmod$ of z and so we can say that the given series converges absolutely if \bmod of z is <1 diverges if \bmod of $z >1$. The test fails if \bmod of $z = 1$ okay. So we have to see what happens in the case $\bmod z = 1$ separately.

(Refer Slide Time: 16:48)

Hence, the series converges absolutely for $|z| < 1$, diverges for $|z| > 1$. However, when $|z| = 1$, we have;
At $z = 1$, the series becomes

$$\sum_{n=1}^{\infty} \frac{(-1)^{n-1}}{n} \checkmark = 1 - \frac{1}{2} + \frac{1}{3} - \frac{1}{4} + \dots$$

= a convergent series

which is convergent while at $z = -1$, the series becomes

$$\sum_{n=1}^{\infty} \frac{1}{n} \checkmark$$

= $\sum_{n=1}^{\infty} \left(\frac{-1}{n}\right)$

which is divergent.

So the series converges absolutely for $\bmod z < 1$ diverges for $\bmod z >1$, however, when \bmod of $z = 1$, the test fails and why it fails we can see that. At $z = 1$ let us look at $z = 1$ what happens, $z = 1$ the series becomes $\sigma_{n=1}^{\infty} -1$ to the power $n-1/n$ you can see, this is what we get at $z = 1$ and this series is what, $1-1/2 + 1/3 -1/4$, so that is a convergent series by Liouville's real test.

Okay so this is convergent at $z = 1$ and at $z = -1$ if you find the series at $z = -1$ what will happen, $\sigma_{n=1}^{\infty} -1$ to the power $n-1 * -1$ to the power n , we will get this series. $\sigma_{n=1}^{\infty} -1$ to the power $n-1 * -1$ to the power n/n and this will be $= - \sigma_{n=1}^{\infty} 1$ upon n okay or we can say we will get the series okay. $\sigma_{n=1}^{\infty} 1$ to infinity $-1/n$ and this series we know this series is divergent because $\sigma_{n=1}^{\infty} 1/n$ is a divergent series, okay.

So we can say that whenever $\text{mod of } z = 1$ here we cannot conclude about the convergence or divergence of the series.

(Refer Slide Time: 18:34)

Let

$$\lim_{n \rightarrow \infty} |f_n(z)|^{\frac{1}{n}} = |s(z)|$$

Then the series $\sum_{n=1}^{\infty} f_n(z)$ converges absolutely for all those values of z for which $0 \leq |s(z)| < 1$ and diverges for those values of z for which $|s(z)| > 1$. The test fails for those values of z for which $|s(z)| = 1$.

Example 3

Test the convergence of the series

$$\sum_{n=1}^{\infty} \frac{1}{n^2} \left| \frac{z-1}{z+1} \right|^{n-1}$$

Now, when $|z-1| = |z+1|$
we get $\sum_{n=1}^{\infty} \frac{1}{n^2}$

Applying the ratio test

$$\lim_{n \rightarrow \infty} \left| \frac{f_{n+1}(z)}{f_n(z)} \right| = \left| \frac{z-1}{z+1} \right|$$

Handwritten work on the slide shows the ratio test calculation:

$$\left| \frac{f_{n+1}(z)}{f_n(z)} \right| = \left| \frac{\frac{1}{(n+1)^2} \left(\frac{z-1}{z+1} \right)^{n^2} \left(\frac{z+1}{z-1} \right)^{n^2}}{\frac{1}{n^2} \left(\frac{z-1}{z+1} \right)^{n-1}} \right|$$

$$= \left(\frac{n}{n+1} \right)^2 \left| \frac{z-1}{z+1} \right|$$

$$\lim_{n \rightarrow \infty} \left| \frac{f_{n+1}(z)}{f_n(z)} \right| = \lim_{n \rightarrow \infty} \left(\frac{n}{n+1} \right)^2 \left| \frac{z-1}{z+1} \right| = \left| \frac{z-1}{z+1} \right|$$

BY ROORKEE
NPTEL ONLINE

13

Now let us consider root test for the series of complex functions. So if limit n tends to infinity $\text{mod of } f_n z$ to the power $1/n = \text{mod of } Sz$ then the series $\sum_{n=1}^{\infty} f_n z$ converges absolutely for all those values of z for which $0 \leq \text{mod of } Sz < 1$ and diverges for those values of z for which $\text{mod of } Sz > 1$. The test fails for those values of z for which $\text{mod of } Sz = 1$.

Let us test the convergence of this series. We are going to consider an example of a series $\sum_{n=1}^{\infty} \frac{1}{n^2} \left(\frac{z-1}{z+1} \right)^{n-1}$ and we can apply here ratio test. So when you apply ratio test what we get $\text{mod of } f_{n+1} z / f_n z$ let us find this is $= \text{mod of } 1/(n+1)^2 \left(\frac{z-1}{z+1} \right)^{n^2} \left(\frac{z+1}{z-1} \right)^{n^2} / \left(\frac{1}{n^2} \left(\frac{z-1}{z+1} \right)^{n-1} \right)$ and this is $f_{n+1} z$ and divided by $f_n z$.

So $n^2 \left(\frac{z-1}{z+1} \right)^{n-1}$ and $z+1$ to the power $n-1$, okay, so this will be $= n^2 / (n+1)^2 \left(\frac{z-1}{z+1} \right)$ okay. So limit of this ratio okay, so limit n tends to infinity $\text{mod of } f_{n+1} z / f_n z$ will be $= \lim_{n \rightarrow \infty} \left(\frac{n}{n+1} \right)^2 \left| \frac{z-1}{z+1} \right|$ okay. So this is $= \left| \frac{z-1}{z+1} \right|$ goes to 1, so this is $= \text{mod of } z-1/z+1$ and therefore we can say that when $\text{mod of } z-1/z+1 < 1$, the given series converges absolutely and when $\text{mod of } z-1/z+1 > 1$ the given series diverges okay.

When $\text{mod of } z-1/z+1 = 1$ we shall have to see what the nature of the series separately.

(Refer Slide Time: 21:12)

Example cont...

Hence the series converges absolutely for those values of z for which $|z - 1| < |z + 1|$ i.e. for values of z which lie in the right half of the z -plane. The series diverges for values of z for which $|z - 1| > |z + 1|$ i.e. for values of z which lie in the left half of the z -plane. Test fails for the values of z for which $|z - 1| = |z + 1|$ i.e. for values of z on the imaginary axis. For points on the imaginary axis, the corresponding series of absolute value is

$$\text{Let } z = iy \Rightarrow \sqrt{(x-1)^2 + y^2} < \sqrt{(x+1)^2 + y^2} \\ \Rightarrow \sqrt{(x-1)^2 + y^2} < \sqrt{(x+1)^2 + y^2} \\ \Rightarrow (x-1)^2 + y^2 < (x+1)^2 + y^2 \\ \Rightarrow x^2 - 2x + 1 < x^2 + 2x + 1 \Rightarrow 4x > 0 \Rightarrow x > 0$$

which is convergent. Thus, the given series converges absolutely for $\Re(z) \geq 0$ and diverges for $\Re(z) < 0$.

So hence the series converges absolutely for those values of z for which mod of $z-1$ is $< z+1$. Now let us see what are the points z where these points are located. Mod of $z - 1$ is the distance of z from the point 1. So $z = 1$ is here and $z = -1$ is here. Now this inequality is valid for all those z whose distance from 1 is $<$ the distance from -1. Okay so this means that the points which lie to the right half of the z plane.

Okay the distance of this z from -1 will always be greater than it is distance from 1 okay. So this means mod of $z - 1 <$ mod of $z + 1$ means real part of $z > 0$ okay. So this inequality tells us that the values of z which lie to the right half of the z plane. Right half of the z plane means for which x is > 0 . We can do it analytically also, here we have done it geometrically. We can do it analytically also.

So let us if we want to do analytically let us put, let z be $= x + iy$ okay then mod of $z - 1 <$ mod of $z + 1$ implies that under root $x - 1$ whole square + y square is $<$ square root $x + 1$ whole square + y square. Squaring both sides, we get $x - 1$ whole square + y square $<$ $x + 1$ whole square + y square. This y square and this y square cancel. You can now open these, so we have $x^2 - 2x + 1 < x^2 + 2x + 1$.

We can cancel 1, x^2 and then what we get $4x > 0$, so which implies that, so $x > 0$ means that the points which lie to the right half of the z plane satisfy the inequality mod of $z-1 <$ mod of $z + 1$ and the series diverges for values of z for which mod of $z - 1$ is $>$ mod

of $z + 1$ that means left half of the z plane. So that means $x > 0$, for values of z which lie to the left half of the z plane that means the values of z for which x is < 0 .

Now test fails for the values of z for which $\text{mod of } z - 1 = \text{mod of } z + 1$, $\text{mod of } z - 1 = \text{mod of } z + 1$ means $x = 0$ okay. If you put here instead of less equality, then we will have $4x = 0$. So $x = 0$, so $\text{mod of } z - 1 = \text{mod of } z + 1$ means the points in the z plane whose distance from 1 and -1 are same. So that is the points which lie on the imaginary axis okay. Any point on the imaginary axis has its distance from 1 and -1 same okay.

So for values of z which lie on the imaginary axis for points on the imaginary axis the corresponding series of absolute value is now let us see what happens. So if you take modulus here okay. $\sum_{n=1}^{\infty} \frac{1}{n^2} \text{mod of } z-1 \text{ upon } z+1 \text{ raise to the power } n-1$ okay. So now when $\text{mod of } z-1 \text{ upon } z+1 = 1$ okay.

We get $\sum \frac{1}{n^2}$ series okay, which we know is a convergence series. So when $\text{mod of } z - 1/z + 1 = 1$ okay we see that this series is convergent and therefore the series is absolutely convergent for values of z which satisfy $\text{mod of } z - 1 \leq \text{mod } z + 1$, and for $\text{mod of } z-1 > \text{mod of } z + 1$ this series is divergent okay. So the series converges absolutely for real part of $z \geq 0$ that is $x \geq 0$.

For $x > 0$ we find from here okay, for $x = 0$ we have seen separately that this series is absolutely convergent and diverges for $x < 0$.

(Refer Slide Time: 26:18)

Example 4

Test the convergence of the series

$$\begin{aligned} & \text{Real } |z+1| \\ & \Rightarrow \sqrt{2x^2+4x+2} < \sqrt{(x+1)^2+1} \\ & \sqrt{2x^2+4x+2} < \sqrt{x^2+2x+2} \\ & 2x^2+4x+2 < x^2+2x+2 \end{aligned}$$

Applying the root test

$$\sum_{n=1}^{\infty} \left(\frac{n-1}{n} \right)^n \left(\frac{z}{z+1} \right)^n$$

$$\lim_{n \rightarrow \infty} |f_n(z)|^{\frac{1}{n}} = \left| \frac{z}{z+1} \right|$$

The series converges absolutely for values of z for which $|z| < |z+1|$ i.e. $\left| \frac{z}{z+1} \right| < 1$. The series diverges for $\left| \frac{z}{z+1} \right| > 1$ i.e. $\Re(z) < -\frac{1}{2}$.

$$\begin{aligned} & \lim_{n \rightarrow \infty} \left| \frac{z}{z+1} \right|^{\frac{1}{n}} \\ & = \left| \frac{z}{z+1} \right| < 1 \text{ abs. conv.} \\ & > 1 \text{ divergent} \\ & \text{The test fails for } \left| \frac{z}{z+1} \right| = 1 \end{aligned}$$

Now let us consider the series $\sum_{n=1}^{\infty} \frac{n-1}{n} \left(\frac{z}{z+1} \right)^n$. So here when we apply root test then limit n tends to infinity $\text{mod of } f_n z$ to the power $1/n$, when you take $1/n$ as root of this $f_n z$ we get $\text{mod of } f_n z$ raise to the power $1/n = n-1/n * z/z+1$ as you know this root test we apply when the n th term of the series contains n in the exponent okay.

So here we have n in the exponent of $n-1/n$ and therefore it will be convenient to apply root test. So this is what we have. Now then limit n tends to infinity if you find $n-1/n$ goes to 1 as n goes to infinity so we get $\text{mod of } z/z+1$ okay and therefore the series converges absolutely for values of z , for which $\text{mod of } z/z+1 < 1$, so absolute convergence for $\text{mod of } z < \text{mod of } z+1$ and divergence for $\text{mod of } z > \text{mod of } z+1$.

The test fails for $\text{mod of } z/z+1 = 1$ okay. The test fails for this, so $\text{mod of } z < \text{mod of } z+1$ means what? It is the set of those points z whose distance from 0 is $<$ this distance from -1 okay and if you take this is 0 here and -1 here. So distance from -1 is $<$ the distance from 0 okay. So this is $-1/2$, okay, this is $-1/2$, so this means that if you take a point to the left of this is $x = -1/2$.

If you take a point to the left of $x = -1$ is distance from -1 will be $<$ is distance from this okay. So this means that we take the right half of this $x = -1/2$, if you take the right $1/2$ then distance of a point from -1 will be more than the distance from 0. So this actually tells us it is real part of $z > -1/2$. We can see it also directly $z = x + iy$ will give you square root $x^2 + y^2 < (x+1)^2 + y^2$ $\text{mod of } z < \text{mod of } z+1$.

If you want to see analytically we can write under root $x^2 + y^2$ for mod of z and here we can write under root $(x+1)^2 + y^2$. So squaring we have $x^2 + y^2 < x^2 + y^2 + 2x + 1$. So these 2 cancel and we get $2x + 1 > 0$ or $x > -1/2$. So right half of the, right side of the line $x = -1/2$ okay this part. Okay so all points z must lie to the right side of $x = -1/2$ and similarly when mod of z is $<$ mod of $z+1$ that is real part of z is $< -1/2$ okay.

So this side okay for all any z to the left of $x = -1/2$ the series is divergent and the series test fails when mod of z / mod of $z+1$ is $= 1$. So test fails for points z which lie on the line $x = -1/2$.

(Refer Slide Time: 30:32)

Example cont...

The test fails for values of z for which $|z| = |z+1|$, the corresponding series of absolute value is

$$\frac{1}{2^2} + \frac{2^3}{3^3} + \frac{3^4}{4^4} + \dots$$

whose general term

$$u_n = \left(\frac{n-1}{n}\right)^n \rightarrow e^{-1} \text{ as } n \rightarrow \infty.$$

Hence the series does not converge absolutely for $\Re(z) = -\frac{1}{2}$. It is seen to be divergent for $\Re(z) = -\frac{1}{2}$.

Handwritten notes on the slide:

- $\sum_{n=1}^{\infty} \left(\frac{n-1}{n}\right)^n$
- $= \left(\frac{1}{2}\right)^2 + \frac{2^3}{3^3} + \frac{3^4}{4^4}$
- $\lim_{n \rightarrow \infty} \left(\frac{n-1}{n}\right)^n = \lim_{n \rightarrow \infty} \left(1 - \frac{1}{n}\right)^n = e^{-1} \neq 0$

Now the test fails for this okay. So the corresponding series absolute value is what let us see when mod of $z/z+1 = 1$ we get the series $\sum_{n=1}^{\infty} n-1/n$ to the power n okay. So when you put $n = 1$ it is 0, when you put $n = 2$ it is $n = 2$ will give you $1/2$ raise to the power 2 okay and $n = 1$ will give 0, so this is what we have $1/2$ raise to the power 2 and then $n = 3$ will give you 2 to the power $3/3$ to the power 3.

And then 3 to the power $4/4$ to the power 4 and so on. So and we can see that $n-1/n$, the n th term of the series $n-1/n$ to the power n we can write as $1-1/n$ upon n raise to the power n okay and so limit n tends to infinity this gives $= e$ to the power -1 okay which is not 0, okay this is not 0 so n th term does not go to 0 and therefore the series is not absolutely convergent okay. So series is not absolutely convergent for real part of $z = -1/2$.

It can be shown that it is divergent for real part of $z = -1/2$. With this I would like to end my lecture. Thank you very much for your attention.
