**Lecture - 18**  
**Residue at a Singularity**

Hello friends. Welcome to my lecture on Residue at a Singularity. The behaviour of singularities into poles and essential singularities.

**(Refer Slide Time: 00:36)**

The classification of singularities into poles and essential singularities is not merely a formal matter, because the behaviour of an analytic function in a neighbourhood of an essential singularity is entirely different from that in the neighbourhood of a pole.

The classification of singularity into poles and essential singularities is not merely a formal matter. Because the behaviour of an analytic function in a neighbourhood of an essential singularity is entirely different from that in the neighbourhood of a pole. Let us see how is the nature of the function in the neighbourhood of a pole. Suppose  $f(z)$  is analytic and has a pole at  $z=z_0$ , then  $\text{mod of } f(z)$  tends to infinity at  $z$  tends to  $z_0$  in any manner.

**(Refer Slide Time: 01:06)**

## Behaviour of a pole

### Theorem 1

If  $f(z)$  is analytic and has a pole at  $z = z_0$ , then  $|f(z)| \rightarrow \infty$ , as  $z \rightarrow z_0$  in any manner.

### Proof

If  $f(z)$  has a pole of order  $m$  at  $z = z_0$ , we can write

$$\begin{aligned}
 f(z) &= (z - z_0)^{-m} \left\{ \sum_{n=0}^{\infty} b_n (z - z_0)^{n+m} + c_m + c_{m-1}(z - z_0) + \dots \right. \\
 &\quad \left. + c_1 (z - z_0)^{m-1} \right\} \checkmark \\
 &= (z - z_0)^{-m} \phi(z) \checkmark
 \end{aligned}$$

$\phi(z) = \sum_{n=0}^{\infty} b_n (z - z_0)^n + \sum_{n=1}^{m-1} c_n (z - z_0)^{n-1}$   
 $= \frac{1}{(z - z_0)^m} \left[ \sum_{n=0}^{\infty} b_n (z - z_0)^{n+m} + c_1 (z - z_0)^{m-2} + c_2 (z - z_0)^{m-3} + \dots + c_{m-1} (z - z_0)^1 + c_m \right]$   
 $\phi(z_0) = c_m \neq 0$

That means in a neighbourhood of  $z=z_0$   $f(z)$  becomes indefinitely large. So if  $f(z)$  has a pole of order  $m$  at  $z=z_0$ , then we can write  $f(z)$  like this, because if  $f(z)$  has a pole of order  $m$  at  $z=z_0$ , then by Laurent series  $f(z) = \sum_{n=0}^{\infty} b_n (z - z_0)^{n+m} + \sum_{n=1}^m c_n (z - z_0)^{-n}$ . So here this is nothing but  $z^1/z - z_0$  to the power  $m$  and then we shall have  $\sum_{n=0}^{\infty} b_n (z - z_0)^{n+m} + c_1 (z - z_0)^{m-2} + \dots + c_{m-1} (z - z_0)^1 + c_m$ .

We have here  $c_1 (z - z_0)$  to the power  $-1$ . So this will be equal to  $m-1$ , okay  $c_2 (z - z_0)$  to the power  $m-2$  and so on  $c_{m-1} (z - z_0) + c_m$ , okay. So we can write like this, okay. If  $z$  has a pole of order  $m$  at  $z=z_0$ . Now this is equal to  $(z - z_0)$  to the power  $-m * \phi(z)$  and  $\phi(z)$  is this Taylor series. You can see here when  $n=0$ , we have  $b_0 (z - z_0)$  to the power  $m$  here. So we can start with this  $c_m, c_{m-1}, z - z_0$ , then  $c_{m-2} (z - z_0)$  square, then  $c_1 (z - z_0)$  to the power  $m-1$ .

Then the term  $z - z_0$  to the power  $m$ , which is  $b_0 (z - z_0)$  to the power  $m$ , then  $b_1 (z - z_0)$  to the power  $m+1$  and so on. So this is the expression inside the square brackets is a Taylor series of some function, which we denote by  $\phi(z)$ .

**(Refer Slide Time: 03:45)**

Proof cont...

where  $\phi(z)$  is analytic in  $|z - z_0| < R$  and  $\phi(z_0) = c_m \neq 0$ .

Hence

$$\lim_{z \rightarrow z_0} |f(z)| = \lim_{z \rightarrow z_0} \left| \frac{\phi(z)}{(z - z_0)^m} \right| = \infty. \checkmark$$

Thus in a sufficiently small neighbourhood of a pole of an analytic function, the absolute value of the function becomes indefinitely large.

Now  $\phi(z)$  is also, you can see  $\phi(z) = c_m$ , which is non-zero, because  $f(z)$  has a pole of order  $m$  at  $z = z_0$ . So  $\phi(z)$  is analytic and  $\text{mod of } z - z_0 < R$  and  $\phi(z_0) = c_m$  where  $c_m$  is non-zero. Now we can take the limit of  $\text{mod of } f(z)$  as  $z$  tends to  $z_0$ , okay.  $\text{Mod of } f(z) = \text{mod } \phi(z) / \text{mod of } (z - z_0)$  to the power  $m$ , so  $f(z)$  goes to  $\infty$ .  $\phi(z)$  is a continuous function, because it is analytic in this region. So it is continuous and also  $\phi(z)$  is not equal to 0.

So  $f(z)$  tends to  $\infty$ , we can see that this expression  $\text{mod of } \phi(z) / (z - z_0)^m$  goes to infinity. So when  $f(z)$  has a pole of order  $m$  in a neighborhood  $f(z)$  in a neighbourhood of  $z = z_0$ ,  $f(z)$  becomes arbitrarily large, okay, so indefinitely large. So thus in a sufficiently small neighbourhood of a pole of an analytic function, the  $m$ th root value of the function becomes indefinitely large.

**(Refer Slide Time: 04:58)**

## Limit point of zeros and poles

### Theorem 2

If  $f(z)$  is an analytic function in a domain  $D$  and if  $z_1, z_2, \dots$  is a sequence of zeros of  $f(z)$  in  $D$  having a limit point in the interior of  $D$ , then  $f(z) \equiv 0$  in  $D$ .

### Proof

Let  $z_0$  be the limit point of the sequence of zeros  $z_1, z_2, \dots$  of  $f(z)$ . Let  $z_0$  be an interior point of the domain  $D$  in which  $f(z)$  is analytic. Then, since  $f(z)$  is continuous at  $z_0$ ,  $f(z_0) = 0$ . Since  $z_0$  is a limit point of the sequence  $z_1, z_2, \dots$  every neighbourhood of  $z_0$ , no matter how small must have infinitely many points of the sequence. This implies that  $z = z_0$  is not an isolated zero of  $f(z)$ . Hence either  $f(z)$  is not analytic or  $f(z) \equiv 0$ . Since  $f(z)$  is given to be analytic, we have  $f(z) \equiv 0$ .

Now suppose, let us look at the limit point of zeroes and poles. If  $f(z)$  is an analytic function in a domain  $D$  and  $z_1, z_2, \dots$  is a sequence of zeroes and  $f(z)$  and  $D$  having a limit point in the interior of  $D$ , then  $f(z)$  is identically 0 in  $D$ . So let us consider that  $z_0$  be the limit point of the sequence of zeroes,  $z_1, z_2$  and so on of  $f(z)$ . Since  $z_0$  is the interior point of the domain  $D$ , okay, it follows that  $f(z)$  is continuous at  $z_0$ , okay,  $f(z)$  is analytic inside  $D$ .

And therefore it is continuous inside  $D$  and  $z_0$  is a point in the interior of  $D$ , so  $f(z)$  is continuous at  $z_0$  and therefore  $f(z_0)$  must be 0. Now let us see how  $f(z_0)=0$ .

**(Refer Slide Time: 05:50)**

$z_1, z_2, \dots$  is a sequence of zeros of  $f(z)$   
and  $z_0$  is the limit point of  $z_1, z_2, \dots$   
 $f(z)$  is continuous at  $z_0$   
 $\Rightarrow$  for a given  $\epsilon > 0 \exists \delta > 0 \Rightarrow$   
 $|f(z) - f(z_0)| < \epsilon$  whenever  $|z - z_0| < \delta$  — (1)  
For  $\delta > 0$  we can find an integer  $n_0$  such that  
 $|z_n - z_0| < \delta, \forall n \geq n_0$  — (2)  
From (1) & (2)  
 $|f(z_n) - f(z_0)| < \epsilon \quad \forall n \geq n_0$   
 $\Rightarrow |0 - f(z_0)| < \epsilon \quad \forall n \geq n_0$   
 $\Rightarrow |f(z_0)| < \epsilon$   
 $\Rightarrow f(z_0) = 0$  since  $\epsilon > 0$  is arbitrary

See we have  $z_1, z_2,$  and so on. This is the sequence of zeroes of  $f(z)$ , okay and  $z_0$  is the limit point of  $z_1, z_2$  and so on. This is the sequence. Now  $f(z)$  is continuous at  $z_0$  implies that for a given  $\epsilon > 0$  there exist a positive number  $\delta$ , such that  $\text{mod of } f(z) - f(z_0) < \epsilon$  whenever  $\text{mod of } z - z_0$  is less than  $\delta$ , okay. Now for  $\delta > 0$ , okay for  $\delta > 0$ , we can find and integer  $n_0$ , such that  $\text{mod of } z_n - z_0 < \delta$  for all  $n \geq n_0$ , okay.

So what will happen,  $\text{mod of } z_n - z_0$  is  $< \delta$  for all  $n > R = n_0$ . Let us combine the equation 1 and 2, okay. From 1 and 2, we find that  $\text{mod of } f(z_n) - f(z_0) < \epsilon$  for all  $n \geq n_0$ , because all these points  $z_n$ , for which  $n \geq n_0$ , they are at a distance  $\delta$  less than  $\delta$  from  $z_0$  and so by the definition of continuity  $\text{mod of } f(z_n) - f(z) < \epsilon$ . This implies that  $\text{mod of } 0 - f(z) < \epsilon$  for all  $n \geq n_0$ , okay. So this we mean that  $\text{mod of } f(z_0) < \epsilon$ , okay.

So this means that  $f(z_0) = 0$  since  $\epsilon > 0$  is arbitrary and thus we can say that because of the continuity of  $f(z)$ ,  $f(z) = z_0$  and  $z_0$  being the limit point of the sequence of zeroes at  $z_1, z_2,$  and so on, it follows that  $f(z_0) = 0$ ; so this  $f(z_0) = 0$ , now since  $z_0$  is a limit point of this sequence  $z_1, z_2$  and so on, okay. So every neighbourhood of  $z_0$ , howsoever a small be it, will have infinitely many points of the sequence  $z_1, z_2$  and so on.

This implies that  $z = g(z_0)$ , okay, is not an isolated zero of  $f(z)$ , okay. It is not an isolated zero of  $f(z)$  and therefore  $f(z)$  must be identically  $= 0$ . So if  $f(z)$  is an analytic function and  $z_1, z_2, z_n$  is a sequence of zeroes, having a limit point in the interior of  $D$ , then  $f(z)$  must be identically  $0$ .

**(Refer Slide Time: 09:47)**

From the above theorem it follows that the limit point of the sequence of zeros of a non zero function, analytic in a domain D, can not be an interior point of D. If it is an interior point of D then either  $f(z) \equiv 0$  or it can not be analytic at the limit point. If the sequence of zeros of a non-zero analytic function is a singularity of  $f(z)$ , it is an isolated singularity. Since, it is not a pole, it is an isolated essential singularity.

### Example 3

The function  $f(z) = \sin \frac{1}{z}$  has zeros at  $z = \frac{1}{n\pi}$ ,  $n = \pm 1, \pm 2, \dots$ . The limit point of these zeros is the point  $z = 0$ . Hence  $z = 0$  is an isolated essential singularity of  $f(z)$ .

$$\begin{aligned} \sin \frac{1}{z} = 0 &\Rightarrow \frac{1}{z} = n\pi, \quad n = \pm 1, \pm 2, \dots \\ \Rightarrow z &= \frac{1}{n\pi}, \quad n = \pm 1, \pm 2, \dots \\ \text{The limit point of this sequence} & \text{ is } \underline{z=0} \end{aligned}$$

Now from the above theorem, it follows that the limit point of the sequence of zeroes of a non-zero function, which is analytic in a domain D cannot be an interior point of D. If it is interior point of D, then  $f(z)$  must be identically 0. So if the sequence of zeroes of a non-zero analytic function is a singularity of  $f(z)$ , it is an isolated singularity. No this isolated singularity cannot be a pole, okay.

Because in the neighbourhood of, in any neighbourhood of this singularity,  $f(z)$  is not becoming indefinitely large. Every neighbourhood of  $z$ =this singularity at  $z$ =say  $z_0$ , okay, we have infinitely many zeroes of the function  $f(z)$ , okay. Since  $f(z)$  does not become indefinitely large in any neighbourhood of this singularity at  $z$ =say  $z_0$ , it follows that it is a not pole. Therefore, it must be an isolated essential singularity.

So to discard this case, that this is not a pole, we are using this theorem, okay, because poles are isolated singularities. So here we are finding an isolated singularity, but that isolated singularity cannot be a pole. If it is a pole, then in an arbitrarily small neighbourhood of  $z=z_0$ ,  $f(z)$  must tend to infinity as  $z$  tends to  $z_0$ , but here what do we notice, howsoever a small neighbourhood of  $z_0$  be there, there are infinitely many zeros of the function  $f(z)$ .

And therefore  $f(z)$  tends to infinity is not possible. So the singularity at  $z=z_0$  cannot be a pole, it must be an isolated essential singularity. So this means that if the analytic function  $f(z)$  is non-

$z=0$ . We can see that  $e$  to the power  $1/z$  is never 0 for any complex number  $z$ . To show that, let us consider  $f(z)$ , let us multiply  $e$  to the power  $1/z$  by  $e$  to the power  $1/\bar{z}$ , okay.

Then this is  $e$  to the power  $1/z + 1/\bar{z}$ , okay, which is equal to  $e$  to the power  $z + \bar{z} / z\bar{z}$ , okay and if  $z = x + iy$ ,  $\bar{z}$  will be  $x - iy$ . So this will be  $e$  to the power  $2x / \text{mod of } z \text{ square}$ .  $z\bar{z}$  is  $\text{mod of } z \text{ square}$ , so this is  $x^2 + y^2$ , okay, so  $x^2 + y^2$  and  $z$  is a non-zero complex number. So this  $e$  to the power  $2x / (x^2 + y^2)$ . This is the real function, okay  $2x / (x^2 + y^2)$  is a real number, okay.

So this is  $e$  to the power  $y$  where  $y$  is  $2x / (x^2 + y^2)$  and  $e$  to the power  $y$ , we know,  $e$  to the power  $y$  is always  $> 0$  for every  $y$ , okay for every  $y$  belonging to  $\mathbb{R}$ , okay. So  $e$  to the power  $z$ , thus  $e$  to the power  $1/z$  can never be 0 for any  $z$ , for any complex number  $z$ , for any  $z \neq 0$ , okay. Now let us show that it assumes every value, okay, in an arbitrary small neighbourhood of  $z=0$ , okay, except of course can never be 0, okay.

Now let us say let  $z$  be equal to  $R e^{i\theta}$  and  $c = c_0 e^{i\alpha}$  be any complex number, okay  $c = c_0 e^{i\alpha}$  where  $c$  is not zero be any complex number, then  $e$  to the power  $1/z = e$  to the power  $1/R e^{-i\theta}$  will be equal to  $e$  to the power  $1/R \cos\theta - i \sin\theta$ , okay  $e$  to the power  $1/R * e^{-i\theta}$  is  $e$  to the power  $1/R \cos\theta - i \sin\theta$ . Let us put it equal to  $c_0 e^{i\alpha}$ , okay.

This  $c_0 e^{i\alpha}$ , so then equating the absolute values and arguments on both sides, you see we have  $e$  to the power  $1/R \cos\theta$ , left side is  $e$  to the power  $1/R \cos\theta * e^{-i/R \sin\theta} = c_0 e^{i\alpha}$ . So taking absolute values both sides, we find that  $e$  to the power  $1/R \cos\theta = c_0$  and equating the arguments what we get  $\alpha = -1/R \sin\theta$ , okay. So now this equation gives you  $e$  to the power  $1/R \cos\theta = c_0$ .

$e$  to the power  $1/R \cos\theta = c_0$  implies that  $1/R \cos\theta = \ln c_0$ , okay and  $\alpha = -1/R \sin\theta$  gives you what or we can say  $\cos\theta = R \ln c_0$ , okay and  $\sin\theta = -\alpha R$ , okay  $\sin^2\theta + \cos^2\theta = 1$ , so we can say that  $R^2 \alpha^2 + R^2 \ln c_0^2 = 1$  or

we can say  $R^2 = 1/\ln c_0^2 + \alpha^2$  and  $\tan \theta = -\alpha/R/\ln c_0$ , so  $\tan \theta = -\alpha/\ln c_0$ , okay. Now let us see  $R$  can this  $R$ ,  $R$  is the modulus of  $z$ , okay.

This  $R$  can be made arbitrarily small by adding multiples of  $2\pi$  to this  $\alpha$ .  $\alpha$  is the argument of this complex number  $c$  and adding multiples of  $2\pi$  to  $\alpha$ , this  $c$  will remain unaltered, okay. So we notice that we obtain.

**(Refer Slide Time: 19:53)**

we obtain

$$r^2 = \frac{1}{(\ln c_0)^2 + \alpha^2} \quad \text{where } c = c_0 e^{i\alpha} \checkmark$$

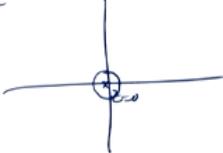

$$\tan \theta = -\frac{\alpha}{\ln c_0}$$

$r$  can be made arbitrarily small by adding integer multiples of  $2\pi$  to  $\alpha$  leaving  $c$  unaltered

$$d = d + 2m\pi$$

$$c = c_0 e^{i(d+2m\pi)} = c_0 e^{id}$$

$z = r e^{i\theta}$

$R^2 = 1/\ln c_0^2 + \alpha^2$  and  $\tan \theta = -\alpha/\ln c_0$ , okay where we have taken  $c = c_0 e^{i\alpha}$ , okay. Now what we notice here is that  $R$  can be made arbitrarily small by adding integer multiples of  $2\pi$  to  $\alpha$ , okay. So we can replace  $\alpha$  by  $\alpha + 2n\pi$ , okay where  $n$  is an integer, okay, but that will not change the value of  $c$ ,  $c$  will remain  $c_0 e^{i\alpha}$  if you take, it will remain  $c_0 e^{i\alpha}$ .

So without changing the value of this  $c$ , so  $c = c_0 e^{i\alpha}$  again. So without, so  $R$  can be made arbitrarily small by adding integer multiples of  $2\pi$  to  $\alpha$ , but  $c$  remains, leaving  $c$  unaltered, okay. Now what we have seen. You take any complex number  $c = c_0 e^{i\alpha}$  where  $c$  is of course non-zero, okay then in an arbitrarily small neighbourhood of  $z = 0$ , okay. See this  $Rz$  we have taken as  $R e^{i\theta}$ , okay.

So in an arbitrarily small neighbourhood of  $z=0$ , because when you add integer multiples of  $2\pi i$  to  $\alpha$ , then this  $R$  will go on becoming small, so  $R$  can be made arbitrarily small by adding integer multiples of  $2\pi i$  to  $\alpha$  and this gives you a neighbourhood of  $z=0$ . So in an arbitrarily small neighbourhood of  $z$ , okay,  $e$  to the power  $1/z$  assumes is an arbitrary complex number. This is an arbitrary complex number other than 0, okay. Now let us go to residue at a singularity.

**(Refer Slide Time: 22:49)**

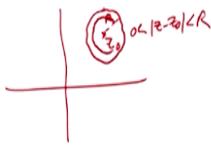

Residue at a singularity

Let  $f(z)$  have an isolated singularity at a point  $z = z_0$  then we can represent  $f(z)$  by a Laurent series

$$f(z) = \sum_{n=0}^{\infty} b_n(z - z_0)^n + \sum_{n=1}^{\infty} \frac{c_n}{(z - z_0)^n} \quad (1)$$

which converges in the domain  $0 < |z - z_0| < R$ , where  $R$  is the distance from  $z_0$  to the nearest singular point of  $f(z)$ .

$$c_n = \frac{1}{2\pi i} \int_C \frac{f(z) dz}{(z - z_0)^{n+1}}, \quad n = 1, 2, \dots$$

$$\Rightarrow \underline{c_1} = \frac{1}{2\pi i} \int_C f(z) dz \quad \checkmark = \text{Res } f(z)_{z=z_0}$$

Let  $f(z)$  have an isolated singularity at a point  $z=z_0$ . Isolated singularity means you can find a neighbourhood of  $z=z_0$  in which  $f(z)$  does not have any other singularity, okay. Then,  $f(z)$  can be represented by Laurent series  $f(z)=\sum_{n=0}^{\infty} b_n(z-z_0)^n + \sum_{n=1}^{\infty} c_n/(z-z_0)^n$ . This series converges in a deleted neighbourhood of  $z_0$ . So if you have  $z_0$  point here, okay.

Then you can find the neighbourhood of  $z_0$ , okay, which is a deleted neighbourhood, okay.  $R$  is the distance of  $z_0$  from the nearest singularity of  $f(z)$ . So in this neighbourhood  $f(z)$  can be represented by the Laurent series given by this.

**(Refer Slide Time: 23:54)**

From the Laurent series expansion, we find that the coefficient  $c_1$  of  $\frac{1}{z - z_0}$  in this development is

$$c_1 = \frac{1}{2\pi i} \int_C f(z) dz$$

or

$$\int_C f(z) dz = 2\pi i c_1, \quad (2)$$

where the integration being taken in the counter-clockwise sense around a simple closed path  $C$  which lies in the domain  $0 < |z - z_0| < R$  and contains the point  $z = z_0$  in its interior. The coefficient  $c_1$  in the development (1) of  $f(z)$  is called the residue of  $f(z)$  at  $z = z_0$ . We shall denote it as  $c_1 = \text{Res}_{z=z_0} f(z)$ .

From the Laurent series expansion, we find that the coefficient  $c_1$  of  $1/(z-z_0) = 1/2\pi i \int_C f(z) d(z)$  or we can say  $\int_C f(z) d(z) = 2\pi i c_1$ . Let us call that in the Laurent series  $c_n$ s are given by  $1/2\pi i \int_C f(z) d(z)/(z-z_0)$  to the power  $-n+1$ , okay  $n$  taking values 1, 2, 3 and so on, okay. So here if you take  $n=1$ , here taking  $n=1$  what do you get  $1/2\pi i c_1$ , okay gives you  $1/2\pi i \int_C f(z) d(z)$ , okay. So when you take  $n=1$  here, you get the value of  $c_1$ .

This  $c_1$  is called the residue of  $f(z)$  at  $z=z_0$ . Residue of, can be denoted like this, residue of  $f(z)$  at  $z=z_0$ , okay. This is coefficient of  $1/z_0$  you can see. This is  $c_1/z-z_0$  like that. The coefficient of  $1/z-z_0$  is  $c_1$  here, okay and the  $c$  is the simple closed curve,  $c$  is any simple closed curve, which lies in the annular region this 1, annular region and in circles  $z_0$  that is  $z_0$  lies in its interior. So it can be taken any simple closed curve like this, okay, which lies in the annular region  $0 < \text{mod of } (z-z_0) < R$  and encircles the inner circle, point circle.

So we can say this is  $\int_C f(z) d(z) = 2\pi i c_1$  where the integration being taken in the counter clock by sense around a simple close past  $c$ , which lies in the region  $0 < \text{mod of } (z-z_0) < R$  and contain the point  $z=z_0$  in its interior. The coefficient  $c_1$  in the development 1 of  $f(z)$ , in this development the coefficient of  $c_1$ , the coefficient  $c_1$  is called the residue of  $f(z)$  at  $z=z_0$  be denoted by residue of  $f(z)$  at  $z=z_0$  like this.

**(Refer Slide Time: 26:21)**

Since Laurent series of  $f(z)$  can be obtained by different methods without using the integral formulas for the coefficients, we can use any of those methods to obtain the residue  $c_1$  and then obtain the value of the contour integral in (2). Formula in (2) can thus be used for evaluating contour integrals.

### Example 6

Evaluate  $\int_C z^2 e^{1/z} dz$ , where  $C: |z| = 1$  (positively oriented).

$e^z = 1 + z + \frac{z^2}{2!} + \frac{z^3}{3!} + \dots$   
 $e^{1/z} = 1 + \frac{1}{z} + \frac{1}{2!z^2} + \frac{1}{3!z^3} + \dots$

Here  $f(z) = z^2 e^{1/z} = z^2 \left[ 1 + \frac{1}{z} + \frac{1}{2!z^2} + \frac{1}{3!z^3} + \dots \right]$

Coeff. of  $\frac{1}{z} = c_1 = \frac{1}{3!} = \frac{1}{6}$

$\int_C z^2 e^{1/z} dz = 2\pi i c_1 = \frac{2\pi i}{6} = \frac{\pi i}{3}$

Now Laurent series of  $f(z)$  can be obtained by different methods without using the integral formulas for the coefficients. You know, we have the integral formulas for the coefficients  $b_n$  and  $c_n$ . For  $c_n$  we have this formula and for  $b_n$  we have the formula  $\frac{1}{2\pi i} \int_C f(z) dz / (z - z_0)^{n+1}$  where  $n=0, +1, +2$  and so on, okay. So Laurent series of a function  $f(z)$  are obtained by different methods without using rarely the formulas for the coefficients are used.

Okay, we use alternate methods to find the Laurent series of  $f(z)$  in a given annular region. So we obtain the Laurent series of the function  $f(z)$  by any alternate method and then we determine the coefficient of  $1/z - z_0$  in that, which gives us the value of  $c_1$ . Then the integral of  $f(z) dz$  around the curve  $C$  is given by  $2\pi i c_1$ , okay. We can use that Laurent series to determine the contour integral. So for example, let us consider this function.

Integral  $\int_C f(z) dz$  square  $e$  to the power  $1/z$  here  $f(z) = z^2 e^{1/z}$ , which we can write as  $z^2 \cdot$  let us write the expansion of  $e$  to the power  $1/z$ . We know that  $e$  to the power  $z$  is  $1 + z + \frac{z^2}{2!} + \frac{z^3}{3!} + \dots$  and so on. So replacing  $z$  by  $1/z$  we get  $e$  to the power  $1/z$  as  $1 + \frac{1}{z} + \frac{1}{2!z^2} + \frac{1}{3!z^3} + \dots$  and so on, which converges in the region  $0 < \text{mod of } z < \infty$ . So here  $1 + \frac{1}{z} + \frac{1}{2!z^2} + \frac{1}{3!z^3} + \dots$  and so on.

We get this. So this is  $z^2 + z + \frac{1}{2!} + \frac{1}{3!z} + \frac{1}{4!z^2} + \dots$  and so on we get, okay. Now this is the Laurent series of the function  $f(z)$  in the region  $z < \text{mod of}$

$z < \infty$ , okay.  $z=0$  is the only singularity of  $f(z)$  and this is an essential singularity you can see, because the principle part, this is the part, which is sigma this part. This part is corresponding to sigma  $n=0$  to infinity  $b_n z$  to the power  $n$ .

Here we are taking  $z_0=0$  and this part, okay corresponds to sigma  $n=1$  to infinity  $c_n z$  to the power  $-n$ , okay. So the principle part contains infinitely many terms and therefore the singularity at  $z=0$  is an essential singularity. So  $f(z)=z^2/1/z$  has an isolated essential singularity at  $z=0$  and the coefficient of, now let us find the coefficient of  $1/z-z_0$ ,  $z_0$  is 0 here. So coefficient of  $1/z=c_{-1}=1/3$  factorial, which is  $1/6$ , okay.

So integral  $\int_C z^2 e^{1/z} dz$  will be equal to  $2\pi i c_{-1}$ , okay. So  $2\pi i/6$  and we get  $\pi i/3$ , okay, but the integral around  $C$  is being taken in the counter clock by chance. Now let us take one more example.

**(Refer Slide Time: 30:29)**

**Example 7**

Evaluate  $\int_C \frac{\sin z}{z^4} dz$ , where  $C: |z|=1$  (positively oriented).

$$\frac{\sin z}{z^4} = \frac{1}{z^4} \left[ z - \frac{z^3}{3!} + \frac{z^5}{5!} - \frac{z^7}{7!} + \dots \right]$$

$$= \frac{1}{z^3} - \frac{1}{3!} z + \frac{1}{5!} z^1 - \frac{1}{7!} z^3 + \dots \quad 0 < |z| < \infty$$

Since the principal part contains only 2 terms we have a pole at  $z=0$  of order 3

Coeff of  $\frac{1}{z} = -\frac{1}{3!} = -\frac{1}{6} = c_{-1}$

$$\int_C \frac{\sin z}{z^4} dz = 2\pi i c_{-1} = 2\pi i \left(-\frac{1}{6}\right) = -\frac{\pi i}{3}$$

Let us take one more example, say integral  $\int_C \sin z/z$  to the power  $d(z)$ , okay. You can see that  $\sin z/z$  to the power 4 can be expressed as  $1/z$  to the power 4 and we know the expansion of  $\sin z$  ( $z - z^3/3!$  factorial  $z^5/5!$  factorial and so on and this is therefore  $z/z^3$  cube, so  $1/z^3$  cube  $-z/3!$  factorial and then we have  $1/3!$  factorial  $*z$ , okay. Then  $1/5!$  factorial  $*z$ , okay and then we have  $-1/7!$  factorial into  $z$  to the power 3 and so on. Now here you can see.

The principle part contains only finitely many terms. There are only 2 terms in the principle part  $1/z^3 - 1/3 \text{ factorial } z$ , okay. Since the principle part contains only finitely many terms we have a pole at  $z=0$ . We have a pole at  $z=0$  of order 3. We have  $-1/3 \text{ factorial} * 1/z + 1/z^3$ . So it is of order 3, the coefficient of  $1/z = -1/3 \text{ factorial}$  that is  $-1/6$ . So this is the value of  $c_1$  and therefore the integral/c or  $\sin z/z$  to the power 4, okay  $d(z) = 2\pi i * c_1$ , which is  $2\pi i * -1/6$ .

And this is  $-\pi i/3$  and you can notice that the region of convergence is  $0 < \text{mod } z < \infty$ .  $\text{Mod } z=1$  is the circle, this 1. This is  $\text{mod } z=1$ , okay. So this is 0, okay,  $\text{mod } z=1$  is the simple closed curve, which lies in this region, okay  $0 < \text{mod } z < \infty$  and contains the point  $z=0$  in its integral, same is the case here in the previous example, the region of convergence is  $0 < \text{mod } z < \infty$  and  $\text{mod } z=1$  lies in this annular region and encircles the point  $z=0$ , this point.

This is  $\text{mod } z=1$ , okay. This is how we can use the Laurent series to determine a contour integration. In our next lecture, we shall study the residue theorem, which will be an extension to of this case. Here, we have only 1 singularity inside the simple closed path  $c$ . So this method will be extended to the case where the curve  $c$  contains finite number of singularities inside it, okay and then it is a very simple and elegant method to determine the contour integration in case the curve  $c$  has infinite number of isolated singularities inside it.

So with this I would like to end my lecture. Thank you very much for your attention.
