Lecture – 22
Evaluation of Real Integrals Using Residues - II

Hello friends, welcome to my lecture on evaluation of real integrals using residues. We will consider some more cases where the real integrals we evaluated using the residue method let us first consider the real integrals in improper real integrals of the form integral over $-\infty$ to ∞ $f(x) \cos sx dx$. and integral over $-\infty$ to ∞ $f(x) \sin sx dx$.

(Refer Slide Time: 00:53)

Improper Real Integrals of the Form $\int_{-\infty}^{\infty} f(x) \cos sx dx$ and
 $\int_{-\infty}^{\infty} f(x) \sin sx dx$

Such type of real integrals occur in the connection with the fourier integral. If $f(x)$ is a rational function satisfying the conditions of the previous article then we may consider the corresponding counter integral

$$\int_C f(z) e^{isz} dz \quad (s > 0)$$

over the contour C .

$\int_{-\infty}^{\infty} f(x) \cos sx dx$ you might have seen such type of real integrals occurring connection with the Fourier integral if $f(x)$ is the rational function satisfying the conditions of the previous article in the previous article when we evaluated the integral of $f(x)$ over $-\infty$ to ∞ interval we had considered $f(x)$ to be a rational function of x that is $f(x) = \frac{p(x)}{q(x)}$ where $q(x)$ does not vanish for any x and the degree of $q(x)$ is at least 2 units are when the degree of $p(x)$.

So, we assume the same conditions here on the function $f(x)$ so if $f(x)$ is a rational function satisfying those conditions then we may consider the corresponding contour integral, so we are considering the contour integral $\int_C f(z) e^{isz} dz$ where s is positive now contour C

consist of the semi-circle with the center of the origin and radius r which we denote by γ and then it consist of the line segment from $-r$ to r along the x axis.

So, c consists of 2 parts 1 is the semi-circle with the center at d origin and radius r which we denote by γ and the other part is integral other part is the line segment from $-r$ to r along the real axis so let us consider the integral/c $fz e^{isz} dz$ and c to be is contour.

(Refer Slide Time: 02:36)

Then

$$\int_C f(z) e^{isz} dz = \int_{\gamma} e^{isz} f(z) dz + \int_{-r}^r e^{isx} f(x) dx$$

where r is taken to be so large that all the poles of $f(z)$ in the upper half of the z -plane lie inside C .

By residue theorem

$$\int_C f(z) e^{isz} dz = 2\pi i \sum \text{Res} \{f(z) e^{isz}\}$$

Now,

$$\int_{-r}^r e^{isx} f(x) dx = 2\pi i \sum \text{Res} \{f(z) e^{isz}\} - \int_{\gamma} e^{isz} f(z) dz$$

And what we notice is that we can write integral/c $fz e^{isz} dz =$ integral/ γ $e^{isz} f(z) dz +$ integral/ $-r$ to r but when we go from $-r$ to r we are moving along the x axis so the imaginary part of z is 0 that is by 0 and we can then take $z=x$ and so while moving along the line segment from $-r$ to r we put x for z so integral/ $-r$ to r $e^{isz} f(z) dz =$ integral/ $-r$ to r $e^{isx} f(x) dx$.

Now let us take because r is at our choice the radius of the semi-circle at our choice so let us choose r to be so large that all the poles of fz which lie in the upper half plane come within the contour c so c encloses all the poles of fz that lie in the upper half plane. Let us take r to be sole r by the residue theorem the integral/c $fz e^{isz} dz$ will be $2\pi i$ times sigma residue of $fz e^{isz}$ where sigma residue $fz e^{isz}$ means.

We find the residue of $fz e$ to the power isz at all the poles that lie in the upper half plane and take their sum and multiply by $2\pi i$ to get the value of integral $\int_{-\infty}^{\infty} f(x) e^{isx} dx$ and then can be written as $2\pi i \sum \text{residue } fz e \text{ to the power } isz - \text{integral} / \gamma e \text{ to the power } isz f(z) dz$.

(Refer Slide Time: 04:23)

Let $r \rightarrow \infty$, then we shall show that

$$\int_{\Gamma} e^{isz} f(z) dz \rightarrow 0$$

Hence,

$$\int_{-\infty}^{\infty} f(x) \cos sx dx = -2\pi \sum \Im \text{Res} \{f(z) e^{isz}\}$$

and

$$\int_{-\infty}^{\infty} f(x) \sin sx dx = 2\pi \sum \Re \text{Res} \{f(z) e^{isz}\}$$

where

$$\alpha = \Re \sum \text{Res} (e^{isx} f(x))$$

$$\beta = \Im \sum \text{Res} (e^{isx} f(x))$$

where

$$\int_{-\infty}^{\infty} f(x) e^{isx} dx = 2\pi i \sum \text{Res} (e^{isx} f(x))$$

$$\int_{-\infty}^{\infty} f(x) \cos sx dx = 2\pi \sum \Re \text{Res} \{f(z) e^{isz}\}$$

$$\int_{-\infty}^{\infty} f(x) \sin sx dx = 2\pi \sum \Im \text{Res} \{f(z) e^{isz}\}$$

Now let us take r to go to infinity then we shall show that integral $\int_{\Gamma} e^{isz} f(z) dz$ goes to 0 and once we get this what will happen then integral $\int_{-\infty}^{\infty} f(x) e^{isx} dx$ will be $= 2\pi i$ times sigma residue $fz e$ to the power $isz dz$ so we will have integral $\int_{-\infty}^{\infty} f(x) e^{isx} dx = 2\pi i$ times sigma residue of e to the power $isz * fz$.

So, what we will do now let us we may write this further integral $\int_{-\infty}^{\infty} f(x) e^{isx} dx$ to the power isx we can write it as $\cos sx + i \sin sx dx = 2\pi i$ times okay now let us say sigma residue is r to the power $isz fz$ is some complex number say $\alpha + i \beta$ where α is real part of sigma residue of e to the power $isz * fz$ and $\beta =$ imaginary part of sigma residue e to the power $isz * fz$ then what will happen when we get real imaginary parts.

We will have integral $\int_{-\infty}^{\infty} f(x) \cos sx dx =$ now this is $2\pi i * \alpha$ then $2\pi i * \beta$ will be $-2\pi \beta$ so this will be $-2\pi \beta$ because on the right side real part $-2\pi \beta$ and integral $\int_{-\infty}^{\infty} f(x) \sin sx dx = 2\pi \alpha$ so what we will have integral $\int_{-\infty}^{\infty} f(x) e^{isx} dx = 2\pi i \alpha$

infinity $\int_{-\infty}^{\infty} f(x) \cos sx dx = -2\pi i$ times imaginary part of sigma residue of $fz e$ to the power isz whether we write imaginary part here or we write imaginary part here the same thing.

Because we are taking summation later on so sigma residue imaginary part of residue of $fz e$ power isz that is beta. So that is multiplied by $-2\pi i$ here we have integral/ - infinity to infinity $\int_{-\infty}^{\infty} f(x) \sin sx dx = 2\pi i$ times real part of this summation r summation of the real parts sigma is the real part of residue of $fz e$ to the power isz for every z which lies which is a pole and lies in the upper half plane. Now let us show that integral/ gamma e to the power isz $fz dz$ goes to 0 or goes to infinity.

(Refer Slide Time: 07:54)

For sufficiently large r_0 such that $|z| = r > r_0$,

$$\begin{aligned} |f(z)e^{isz}| &= |f(z)| |e^{is(x+iy)}| \\ &= |f(z)| e^{-sy} \leq |f(z)| < \frac{M}{r^d}, \end{aligned}$$

where $d \geq 2$ and M is any number greater than $|\frac{a_n}{b_m}|$. Thus

$$\begin{aligned} \left| \int_r f(z)e^{isz} dz \right| &< \frac{M}{r^d} \cdot \pi r \\ &= \frac{\pi M}{r^{d-1}} \rightarrow 0, \end{aligned}$$

as $r \rightarrow \infty$.

$$\begin{aligned} |e^{is(x+iy)}| &= |e^{isx} \cdot e^{-sy}| \\ &= |e^{isx}| / |e^{-sy}| \\ &= e^{-sy} \\ f(x) &= \frac{p(x)}{q(x)} \\ q(x) &\neq 0 \\ \& \text{ degree } q(x) \\ &- \text{ degree } p(x) \\ &= d \geq 2 \\ \text{Since } s > 0 \\ \text{and } y > 0 \\ \text{we have} \\ f(z) &= \frac{a_n z^n + a_{n-1} z^{n-1} + \dots + a_0}{b_m z^m + b_{m-1} z^{m-1} + \dots + b_0} e^{-sy} \leq \frac{1}{|z|^{d-1}} \end{aligned}$$

So, mod of $fz e$ to the power isz = mod of fz and to the mod of e to the power isz = $x+iy$ so $x+iy$ we put here and then when you multiply mod of e to the power is $*x+iy$ = mod of e to the power is $x * e$ to the power $-sy$ which = mod of e to the power is $x * \text{mod of } e$ to the power $-sy$ now mod of $\cos i$ mod of e to the power is $x = 1$ okay as s is real and positive so this = e to the power $-s/$ because e to the power $-sy$ which always > 0 .

So, we will have mod of $fz * e$ to the power isz = mod of $fz * e$ to the power $-sy$ now our fz we have assumed to be $=px/qx$ where qx is $\neq 0$ and degree of qx - degree of px let us take = d so than this d is ≥ 2 now in our previous lecture we have seen that when fz satisfies this conditions

than $\text{mod of } fz \leq m/r$ to the power d for sufficiently $r > 0$ that $\text{mod of } z = r$ is $> r^0$ so and e to the power $-sy$ what happened to this e to the power $-sy$.

Since $s > 0$ and y lies in the upper half plane and we are in the upper half plane estimating this $\text{mod of } fz$ e to the power isz for this computing this integral estimating this integral and γ lies in the upper half plane so if you take any point in the γ then $y > 0$ so what we will have since $s > 0$ and $y > 0$ we have e to the power $-sy \leq 1$ on γ this is valid on γ so we can place it for $-sy/y \leq 1$ so this we have M/r to the power d where $d \geq 2$.

And m is any number we have seen $> \text{mod of } a_n/b_m$ where we have taken f_x we have taken f_z we have taken to the $a_n z$ to the power $n + a_{n-1} z$ to the power $n - 1$ and so on $a_1 z + a_0$ and we had taken denominator polynomial to be $b_m z$ to the power $m + b_{m-1} z$ to the power $m - 1$ and so on $= b_1 z + b_0$ then we had seen that if $m - n = d$ and $d \geq 2$ then $\text{mod of } fz \leq m/r$ to the power d where m is any number $> \text{mod of } a_n/b_m$.

So, $\text{mod of } fz$ by Cauchy inequality let us apply Cauchy inequality so integral we have estimated $\int_{\gamma} f(z) dz \leq \text{length of } \gamma \cdot \sqrt{\int_{\gamma} |f(z)|^2 dz}$ so length of γ is πr because γ is semicircle of radius r so M/r to the power $d \cdot \pi r$ so this $\pi M/r$ to the power $d-1$ now $d \geq 2$ so $d - 1 \geq 1$ and therefore it goes to 0 as r goes to infinity so this is how we prove that this integral around γ goes to 0 when r goes to infinity.

(Refer Slide Time: 12:10)

Example 1

Show that

$$\int_{-\infty}^{\infty} \frac{\cos sx}{k^2 + x^2} dx = \frac{\pi}{k} e^{-ks},$$

$$\int_{-\infty}^{\infty} \frac{\sin sx}{k^2 + x^2} dx = 0, \quad (s > 0, k > 0).$$

Let us consider the contour integral $\int_C f(z) e^{isz} dz$, where $f(z) = \frac{1}{k^2 + z^2}$.

Then $\int_C f(z) e^{isz} dz = \int_{-\infty}^{\infty} f(x) e^{isx} dx + \int_{\Gamma} f(z) e^{isz} dz$.

Let us take r to be so large that all the poles of $f(z)$ in the upper half plane lie inside C .

$z^2 + k^2 = 0 \Rightarrow z = \pm ik$

The simple pole at $z = ik$ lies inside C .

$\text{Res}_{z=ik} f(z) e^{isz} = \text{Res}_{z=ik} \frac{1}{k^2 + z^2} e^{isz} = \left[\frac{e^{is(ik)}}{2z} \right]_{z=ik}$.

$g(z) = k^2 + z^2$
 $g'(z) = 2z$

Now let us evaluate integral $\int_{-\infty}^{\infty} \frac{\cos sx}{k^2 + x^2} dx$ and simultaneously we will also be able to get value of the integral $\int_{-\infty}^{\infty} \frac{\sin sx}{k^2 + x^2} dx$ now you can notice here that $\sin sx$ is an odd function $k^2 + x^2$ is an even function so $\sin sx / (k^2 + x^2)$ is an odd function of x and therefore its value $\int_{-\infty}^{\infty}$ interval must be 0.

So, we have to verify that by using residue calculus and here this is an even function $\cos sx$ is an even function $k^2 + x^2$ is an even function so $\cos sx / (k^2 + x^2)$ is an even function when we use the contour integral $\int_C f(z) e^{isz} dz$ then you notice that we get the value of both the integrals simultaneously value of integral $\int_{-\infty}^{\infty} \cos x dx$ and integral $\int_{-\infty}^{\infty} \sin x dx$ by equating real imaginary parts.

So, let us consider the corresponding contour integral here so let us consider the contour integral $\int_C f(z) e^{isz} dz$ now let us notice that here $f(x)$ is $1/(k^2 + x^2)$ so $f(x)$ is a rational function of x where the denominator of the polynomial is up to degree 2 denominator polynomial is $k^2 + x^2$ so its degree is $2n$ and the numerator is constant 1 so it is of degree 0 the difference of the degree in the numerator and the denominator is 2.

Numerator and denominator exceeds by 2 units then the degree of the denominator the degree of the denominator is 2 units higher than the degree of the numerator so those conditions and

moreover that the denominator polynomial $k^2 + x^2$ which we have denoted by $q(x)$ is not 0 for any real value of x so we can apply the article which we have first now studied so let us consider the integral $\int_C \frac{e^{iz}}{f(z)} dz$ where f is this.

Integral we are taking over this path C consist of semicircle γ center at 0 radius r and the real axis is the line segment on the real axis from $-r$ to r so this is our C then we can split integral $\int_C \frac{e^{iz}}{f(z)} dz = \int_{\gamma} \frac{e^{iz}}{f(z)} dz + \int_{-r}^r \frac{e^{ix}}{f(x)} dx$ here $f(z) = \frac{1}{k^2 + z^2}$ so this $\frac{1}{k^2 + z^2}$ alright let us take r has to be so large.

Let us take r to be so large that all the poles of $f(z)$ in the upper half plane lies inside C okay what are the poles of $f(z)$ the $f(z)$ has poles at the points where $z^2 + k^2 = 0$ so $z^2 + k^2 = 0$ gives you $z = \pm i k$ we are given k to be positive so ik lies here $-ik$ lies here so and moreover that denominator if you write $q(z) = k^2 + z^2$ then $q'(z) = 2z$ so $q'(z)$ is not 0 and $z = ik$ and therefore $q(z)$ has a simple pole at $z = ik$.

So, the simple pole at $z = ik$ lies inside C let us find the residue of $f(z)$ at $z = ik$ so this is residue of $f(z)$ is $\frac{1}{k^2 + z^2} \cdot e^{iz}$ at $z = ik$ so we have e^{iz} denominator polynomial differentiate we get $2z$ and then you put $z = ik$ so we get e^{iz} at $z = ik$ so then integral over C .

(Refer Slide Time: 18:21)

By residue theorem $\int_C \frac{1}{k^2+z^2} e^{i\lambda z} dz = 2\pi i \frac{e^{-\lambda k}}{2ik} = \frac{\pi e^{-\lambda k}}{k}$

Thus taking $r \rightarrow \infty$, we have

$$\int_{-\infty}^{\infty} \frac{1}{k^2+x^2} e^{i\lambda x} dx = \frac{\pi e^{-\lambda k}}{k} - \lim_{r \rightarrow \infty} \int_{\Gamma} \frac{e^{i\lambda z} dz}{k^2+z^2} \quad (2)$$

Let us prove that $\lim_{r \rightarrow \infty} \int_{\Gamma} \frac{e^{i\lambda z} dz}{k^2+z^2} = 0$

$$\left| \frac{e^{i\lambda z}}{k^2+z^2} \right| = \left| \frac{e^{i\lambda(x+iy)}}{k^2+z^2} \right| = \left| \frac{e^{i\lambda x} e^{-\lambda y}}{k^2+z^2} \right| \leq \frac{1}{|z|^2-k^2} e^{-\lambda y} = \frac{1}{r^2-k^2} e^{-\lambda y}$$

hence by Cauchy's inequality $\leq \frac{1}{r^2-k^2}$ since $e^{-\lambda y} < 1$

$$\left| \int_{\Gamma} \frac{e^{i\lambda z} dz}{k^2+z^2} \right| \leq \frac{\pi r}{r^2-k^2} \rightarrow 0, \text{ as } r \rightarrow \infty$$

Therefore (2) $\Rightarrow \int_{-\infty}^{\infty} \frac{1}{k^2+x^2} e^{i\lambda x} dx = \frac{\pi e^{-\lambda k}}{k}$

Equating real and imaginary parts by putting $e^{i\lambda x} = \cos \lambda x + i \sin \lambda x$
 $\int_{-\infty}^{\infty} \cos \lambda x dx = \pi e^{-\lambda k}$ $\int_{-\infty}^{\infty} \sin \lambda x dx = 0$

By residue theorem integral $\int_{-\infty}^{\infty} \frac{1}{k^2+x^2} e^{i\lambda x} dx$ this will be $= 2\pi i$ times e to the power $-\lambda k/2ik$ so this cancels and this and we get π times e to the power $-\lambda k/k$ so we have found the value of the integral $\int_C f(z) dz$. Now let us go back and see what we have to do now next so let us take the limit let me call it as equation number 1 let us take r to go to infinity then this will be this we have already evaluated.

So, this will come integral $\int_{-\infty}^{\infty} f(x) e^{i\lambda x} dx$ so that will be $=$ to the value of the residue here multiplied by $2\pi i$ we get the value of this integral $=$ integral $\int_{\Gamma} f(z) dz$ so we have thus taking r to go to infinity we have integral $\int_{-\infty}^{\infty} \frac{1}{k^2+x^2} e^{i\lambda x} dx = \pi$ times e to the power $-\lambda k/k$ $\lim_{r \rightarrow \infty} \int_{\Gamma} \frac{1}{k^2+z^2} e^{i\lambda z} dz = 0$

So, we can so show in the article let us prove that $\lim_{r \rightarrow \infty} \int_{\Gamma} \frac{1}{k^2+z^2} e^{i\lambda z} dz = 0$ so mod of e to the power $|\lambda z|/k^2+z^2$ let us first calculate this so this is mod of e to the power $|\lambda x + i\lambda y|/k^2+z^2$ so this $=$ mod of e to the power $|\lambda x|/k^2+z^2$ e to the power $|\lambda y|/k^2+z^2$ e to the power $|\lambda x|/k^2+z^2$ modules of e power $|\lambda x|/k^2+z^2 = 1$ e to the power $|\lambda y|/k^2+z^2 > 0$ so it will not be affected by mod.

And then this is $\leq 2/\text{mod of } z^2 - k^2 * e \text{ to the power } -\lambda y$ so this is $1/r^2 - k^2 * e \text{ to the power } -\lambda y$ so e to the power $-\lambda y$ let us replace 1 this ≤ 1 so we can write $1/r^2$

square – k square since e to the power $-s < 1$ γ lies in the upper half plane now hence by Cauchy's inequality modules of integral $\int \gamma e$ to the power is $z dz / k^2 + z^2 \leq 1/r^2 - k^2 * \text{length of } \gamma$ which is πr , so this goes to 0 as r goes to infinity.

Thus from this goes to 0 this becomes 0 so therefore let me call it 2 so therefore 2 implies integral $\int_{-\infty}^{\infty} 1/k^2 + x^2 e$ to the power is $x dx = \pi e$ to the power $-sk/k$ now let us put e to the power is $x \cos sx + i \sin x$ and then equate imaginary parts both sides on the right side you see is the real value so imaginary part is 0 so equating real and imaginary parts by putting e to the power is $x = \cos sx + i \sin x$.

So, we get integral $\int_{-\infty}^{\infty} \cos sx / k^2 + x^2 dx = \pi e$ to the power $-sk/k$ while integral $\int_{-\infty}^{\infty} \sin s x dx / k^2 + x^2 = 0$ so this is how we do this problem, so this is the solution to this problem.

(Refer Slide Time: 24:41)

Improper Integrals with Singular Points on the Real Axis

Another kind of improper integral is a definite integral

$$I = \int_a^b f(x) dx$$

whose integrand becomes infinite at a point c in the interval of integration i.e.

$$\lim_{x \rightarrow c} |f(x)| = \infty.$$

Then we express I as

$$\int_a^b f(x) dx = \lim_{\epsilon \rightarrow 0} \int_a^{c-\epsilon} f(x) dx + \lim_{\eta \rightarrow 0} \int_{c+\eta}^b f(x) dx.$$

where both ϵ and η tend to zero independently through positive values.

And now let us go to next article so here we consider improper integrals where we have similar points on the real axis in the previous article, we consider those improper integrals where the integral does not have any similar point on the real axis. It does not become 0 the denominator we had taken $f(x) = p(x)/q(x)$ and we had assumed that $q(x)$ is not 0 for any real axis. So, we considered all those integrals where similarities of the integrand do not lie on the real axis.

Here we consider an improper integral where singularities will lie on the real axis. So, another kind of improper integral is a definite integral $\int_a^b f(x) dx$ whose integrand becomes infinite at a point c in the interval of integration. Here we will see those kind of integrals where there is a point in the interval of integration at which the integrand becomes infinite. That is limit of mod of $f(x)$ and it extends to ∞ and c lies between a and b .

So, when we express I as integral over a to b of $f(x) dx$ limit $\epsilon \rightarrow 0$ of integral over a to $c - \epsilon$ of $f(x) dx$ + integral over $c + \epsilon$ to b of $f(x) dx$ where ϵ goes to 0 and then $c + \eta$ to b okay integral $c + \eta$ to b of $f(x) dx$ where η goes to 0, both ϵ and η both tend to 0 through positive values independently.

(Refer Slide Time: 26:31)

It may happen that neither of these limits exist if ϵ, η tend to zero independently but

$$\int_a^b f(x) dx = \lim_{\epsilon \rightarrow 0} \left[\int_a^{c-\epsilon} f(x) dx + \int_{c+\epsilon}^b f(x) dx \right]$$

exists then this is called the Cauchy principal value of

$$I = \int_a^b f(x) dx$$

and written as

$$pr. v. \int_a^b f(x) dx.$$

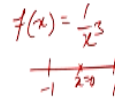

Okay now it may happen that neither of these limits adjust this limit or this limit or both of them may not exist. But limit of integral a to $c - \epsilon$ of $f(x) dx$ + integral $c + \epsilon$ to b of $f(x) dx$ as ϵ tends to 0 exists. So, then this limit is called the Cauchy principal value of integral a to b of $f(x) dx$ and we write it as principal value of a to b of $f(x) dx$. So, for example let us consider this example.

(Refer Slide Time: 27:06)

For example

$$\text{pr. v. } \int_{-1}^1 x^{-3} dx = 0. \checkmark$$

$$f(x) = \frac{1}{x^3}$$

Hence the Cauchy principal value exists but $\lim_{\epsilon \rightarrow 0} \int_{-1}^{-\epsilon} \frac{1}{x^3} dx$ and $\lim_{\eta \rightarrow 0} \int_{\eta}^1 \frac{1}{x^3} dx$ do not exist and so $\int_{-1}^1 \frac{1}{x^3} dx$ does not exist.

In such a case we can extend the method of evaluating $\int_{-\infty}^{\infty} f(x) dx$ where

$$\lim_{\epsilon \rightarrow 0} \int_{-1-\epsilon}^{-\epsilon} \frac{1}{x^3} dx = -\infty$$

$$f(x) = \frac{p(x)}{q(x)}, \quad q(x) \neq 0 \text{ and } \deg q(x) - \deg p(x) \geq 2$$

$$\lim_{\epsilon \rightarrow 0} \left[\int_{-1}^{-\epsilon} \frac{1}{x^3} dx + \int_{\epsilon}^1 \frac{1}{x^3} dx \right]$$

to functions $f(z)$ which have simple poles on the real axis by taking the path which avoids these singularities by following small circles with centers at the singular points.

$$\lim_{\epsilon \rightarrow 0} \left[\int_{-1-\epsilon}^{-\epsilon} \frac{1}{x^3} dx + \int_{\epsilon}^1 \frac{1}{x^3} dx \right] = 0$$

$$= \lim_{\epsilon \rightarrow 0} \left[\left(-\frac{1}{2x^2} \right)_{-1-\epsilon}^{-\epsilon} + \left(-\frac{1}{2x^2} \right)_{\epsilon}^1 \right]$$

You see if we take $f(x) = 1/x^3$ and the integral of integration we take as -1 to 1 then at the point $x=0$ you see $f(x)$ becomes infinite. So, now let us see that the Cauchy principal value exists here so Cauchy principal exists means integral over limit ϵ tends to 0 integral -1 to $-c-\epsilon$ c is 0 here, so $-\epsilon$ $1/x^3 dx$ we have then integral $c+\epsilon$ to 1 so $c+c=0$ so we get $\epsilon^2/2$ here $1/x^3 dx$ okay.

Let us see whether this limit exists so this is $= \lim_{\epsilon \rightarrow 0}$ we have here $-1/x$ to the power -3 means when you integrate you get x to the power $-2/-2$ so $-1/2x^2$ square and then you put the limits $-1-\epsilon$ to $-\epsilon$ we have here same thing $-1/2x^2$ square and you put the limits ϵ to 1 and what do we notice this is $\lim_{\epsilon \rightarrow 0}$ let us put the upper limit so we get $-1/2\epsilon^2$ square and then we get $+1/2$ okay when you put $x=-1$ and here you get what.

$-1/2$ and then you get $1/2\epsilon^2$ square so this cancels with this this cancels with this and what we get is 0 okay. So, the Cauchy principal value of this integral exists and this is $=0$. But you see the limits ϵ tends to 0 $-\epsilon$ $1/x^3 dx$ this limit okay this limit and this limit separately you find they do not exist. Let us see that $\lim_{\epsilon \rightarrow 0} \int_{-1-\epsilon}^{-\epsilon} 1/x^3 dx$ this will be $=$ when you put the limits you will get $-1/2\epsilon^2 + 1/2$ okay.

And you take the limit as ϵ tends to 0 okay you see that the limit when ϵ tends to 0 through positive values this gives you $-\infty$ okay similarly when you find $\lim_{\eta \rightarrow 0} \int_{\eta}^1 1/x^3 dx$ this gives you $+\infty$ okay.

eta to 1 what do you get limit eta tends to 0 you get $-1/2 \times \text{square eta}$ to 1 okay so limit eta tends to 0 and you get $-1/2 + 1/2 \text{ eta square}$ and this becomes $+\infty$ okay so both these limits separately do not exist.

While the Cauchy principal value exists and is $=0$ so we will be considering Cauchy principal value here in such a case we can extend now we will extend the method of evaluating integral $\int_{-\infty}^{\infty} f(x) dx$ where $f(x) = p(x)/q(x)$ where $q(x)$ is not $\equiv 0$ and degree $q(x) - \text{degree of } p(x) \geq 2$ this we have already seen we will extend the method of evaluating such kind of integrals to functions $f(z)$ which have simple poles on the real axis.

By taking the path which avoids these singularities by following small circles with centers at the singular points. Now let us see an example of this.

(Refer Slide Time: 31:27)

Suppose $f(z)$ has a simple pole at $z = a$ on the real axis then integrating $f(z)$ around the contour and applying residue theorem we have

$$\int_{\Gamma} f(z) dz + \int_{-r}^{a-\epsilon} f(x) dx + \int_{\gamma} f(z) dz + \int_{a+\epsilon}^r f(z) dz = \int_C f(z) dz = 2\pi i \sum \text{Res } f(z)$$

Letting $r \rightarrow \infty$, we have

$$\lim_{r \rightarrow \infty \text{ and } \epsilon \rightarrow 0} \left[\int_{-r}^{a-\epsilon} f(x) dx + \int_{a+\epsilon}^r f(z) dz \right] = \text{pr. v.} \int_{-\infty}^{\infty} f(x) dx$$

mod05lec22

We will first consider the general case suppose fz has a simple pole at $z=n$ okay so let us consider the contour this is gamma suppose I have a simple pole here at $z=a$ suppose fz has a simple pole at $z=a$ and the real axis then integrating fz around the contour C is now this this we have this is semi-circle at center a and radius is epsilon okay radius of this semicircle this radius is $=\text{epsilon}$ okay integral/gamma.

When you consider $\int_{-r}^r f(z) dz$, it will be $= \int_{\gamma} f(z) dz + \int_{-r}^r f(x) dx$ this is what you see here. Let me write it separately $-r$ to r this is your point a so I have made a small circle here of radius ϵ okay and here is your origin so $-r$ to $a - \epsilon$ this point is $a - \epsilon$ this point is $a + \epsilon$ okay because ϵ is the radius. So, what do we do we have this figure okay from here we are moving like this so r to $a - \epsilon$.

We integrate along the x axis, so we write $\int_{-r}^r f(x) dx$ then $\int_{\gamma} f(z) dz$ this is $\int_{\gamma} f(z) dz$ this semicircle. So, $\int_{\gamma} f(z) dz + \int_{a+\epsilon}^r f(x) dx + \int_{-r}^{a-\epsilon} f(x) dx$ this is $= \int_{-r}^r f(x) dx$. So, you can see by drawing a small circle with sufficiently small radius with center at the point a we can avoid the singularity at point a okay.

Now letting r go to infinity let us take r to go to infinity then ϵ go to 0 we will have this will become this goes to 0. $\int_{\gamma} f(z) dz$ goes to 0 $\int_{-r}^r f(x) dx + \int_{a+\epsilon}^r f(x) dx + \int_{-r}^{a-\epsilon} f(x) dx$ that gives us the Cauchy principal value of $\int_{-\infty}^{\infty} f(x) dx$. This value is $2\pi i \times \text{sum of residues of } f(z) \text{ that lie in the upper half plane}$ and $\int_{\gamma} f(z) dz$ we shall see how to evaluate separately okay.

So, when taking r to go to infinity and ϵ to go to 0 this becomes Cauchy principal value. So, this part and this part tends to Cauchy principal value of $\int_{-\infty}^{\infty} f(x) dx$ this we have evaluated by using residue theorem. This will go to 0 and this we will see $\int_{\gamma} f(z) dz$ how do we evaluate okay so everything will be known and then we will get the Cauchy principal value of $\int_{-\infty}^{\infty} f(x) dx$.

(Refer Slide Time: 34:58)

On the semi-circle γ , $z = a + \epsilon e^{i\theta}$ and so

$$\int_{\gamma} f(z) dz = \int_{\pi}^0 f(a + \epsilon e^{i\theta}) \epsilon e^{i\theta} i d\theta.$$

Since $z = a$ is a simple pole of $f(z)$, we may write

$$\begin{aligned} f(z) &= b_0 + b_1(z-a) + b_2(z-a)^2 + \dots + \frac{c_1}{z-a} \\ &= g(z) + \frac{c_1}{z-a} \end{aligned}$$

mod05lec22

Now let us see here how we evaluate the integral along gamma okay so this is your figure this is integral/gamma this is r this is r this is x axis this is y axis this is a-epsilon point, and this is a+epsilon and gamma because center is at a and radius is epsilon along gamma $z = a + \epsilon e^{i\theta}$ to the power $i\theta$ okay and since we are moving clockwise along gamma θ varies from π to 0 okay so along gamma, we can write $z = a + \epsilon e^{i\theta}$ because center is at a.

So it will be not z it will be $z-a$ okay $z-a$ will be $= \epsilon e^{i\theta}$ or we can say $z = a + \epsilon e^{i\theta}$. So, $\int_{\gamma} f(z) dz$ will be \int_{π}^0 because θ varies from π to 0 $f(a + \epsilon e^{i\theta})$ and dz is $z = a + \epsilon e^{i\theta}$ gives $dz = \epsilon e^{i\theta} i d\theta$ so this is what you get. Now $z=a$ is a simple pole of fz so by Laurent series expansion fz can be written as $b_0 + b_1(z-a) + b_2(z-a)^2 + \dots + \frac{c_1}{z-a}$.

And so on and the principal part of fz contains only one term that is $c_1/(z-a)$ where c_1 is non-zero. Okay c_1 is the residue of fz at $z=a$. Now this part which contains the positive integral powers of $z-a$ non-negative integral powers of $z-a$ that constitutes a power series which center at $z=a$ so that we can denote by $g(z)$ where $g(z)$ is analytic in some neighborhood of $z=a$ so fz can be written as $g(z) + c_1/(z-a)$

(Refer Slide Time: 37:17)

Hence

$$\begin{aligned}
 \int_{\gamma} f(z) dz &= \int_{\gamma} g(z) dz + \int_{\gamma} \frac{c_1}{z-a} dz \\
 &= \int_{\pi}^0 g(a + \epsilon e^{i\theta}) \epsilon e^{i\theta} i d\theta + c_1 \int_{\pi}^0 i d\theta \\
 &= i\epsilon \int_{\pi}^0 g(a + \epsilon e^{i\theta}) e^{i\theta} d\theta - c_1 i\pi \\
 &= I_1 - i\pi \left(\text{Res}_{z=a} f(z) \right)
 \end{aligned}$$

Handwritten notes on the right side of the slide:

$$\begin{aligned}
 z-a &\approx \epsilon e^{i\theta} \\
 dz &= \epsilon e^{i\theta} i d\theta \\
 \int_{\pi}^0 \frac{c_1 \epsilon e^{i\theta} i d\theta}{\epsilon e^{i\theta}} &= c_1 \int_{\pi}^0 i d\theta \\
 &= -i\pi c_1
 \end{aligned}$$

mod05lec22

And then integral/gamma let us put integral/gamma let us put in place of f a+e i theta f a+epslion e i theta let us put this gz+c1/z-a so we will get integral/gamma gz this integral/gamma fz dz can be written as integral/gamma dz gz +integral/gamma c1/z-a dz now z is a+eplison e i theta dz is epsilon e i theta i d theta so pi 2 0 we get this then c 1 times dz is now let me write this integral/gamma integral/pi to 0 c1.

We have z-a=epsilon e to the power i theta. So, we get epsilon e to the power i theta dz becomes epsilon e to the power i theta * i d theta so epsilon e to the power theta*i d theta and we cancel this out and we get c1 times integral/pi to 0 I d theta which is -i pi*c1 okay so -i pi c1 this is I epsilon we can write outside integral pi to 0 g a+epslion ei theta ei theta d theta or I can write it as let us call this as i1 this I call as i1 i1-I pi *residue of fz at z=a.

This we have seen here c1 is residue of fz =a so I can write i pi times residue of fz=a and then let us evaluate the value of i1.

(Refer Slide Time: 39:10)

Now,

$$|I_1| = \left| i\epsilon \int_{\pi}^0 g(a + \epsilon e^{i\theta}) e^{i\theta} d\theta \right|$$

$$\leq \epsilon M \pi,$$

$$|g(a + \epsilon e^{i\theta})| \leq M$$

where $|g(a + \epsilon e^{i\theta})| \leq M$ on γ . It follows that $I_1 \rightarrow 0$, as $\epsilon \rightarrow 0$. Thus,

$$\lim_{\epsilon \rightarrow 0} \int_{\gamma} f(z) dz = -\pi i \operatorname{Res}_{z=a} f(z)$$

mod05lec22

Now mod of $i\epsilon$ = mod of i epsilon * integral/ π to 0 $g(a + \epsilon e^{i\theta}) e^{i\theta} d\theta$ okay so mod of this quantity. Now $g(z)$ is an analytic function in some neighborhood of a okay therefore integral/ π to 0 $g(a + \epsilon e^{i\theta}) e^{i\theta} d\theta$ this can be evaluated by Cauchy mod of $g(a + \epsilon e^{i\theta}) e^{i\theta}$ this is $\leq M$ okay you see we have a semi-circle okay whose radius is epsilon is very small okay and dz is analytic at $z=a$.

So, some neighborhood of $z=a$ this function is continuous and therefore this gamma we can write that mod of $g(a + \epsilon e^{i\theta}) e^{i\theta} \leq M$ it is bounded in that neighborhood and now so this is epsilon this epsilon we have here and then M for this and then $e^{i\theta}$ mod of integral and then integral/ π 0 $d\theta$ will be $-\pi$ mod of that will be π . So, epsilon $M \pi$ we have and.

So, when epsilon goes to 0 I_1 goes to 0 and therefore limit epsilon goes to 0 $\int_{\gamma} f(z) dz$ that is $= -i \pi \operatorname{Res}_{z=a} f(z)$ so, this is what we get this is how we evaluate the integral along the semi-circle gamma of small radius so this value we shall put here for this expressions we this is $=0$ when r tends to infinity this integral.

And this integral gives us the Cauchy principal value of integral from -infinity to infinity of f(x) dx. This we know by residue theorem and this we have calculated okay. So, we have put the value here okay and then calculate the Cauchy principal value.

(Refer Slide Time: 41:25)

Further $\int_r f(z) dz \rightarrow 0$, as $r \rightarrow \infty$ because $f(z) = \frac{p(z)}{q(z)}$ is a rational function and $\deg q(z) - \deg p(z) \geq 2$. Thus

$$\text{pr. v.} \int_{-\infty}^{\infty} f(x) dx = 2\pi i \sum \text{Res}(f(z)) + \pi i \left(\text{Res}_{z=a} f(z) \right).$$

If $f(z)$ has finite number of simple poles on the real axis then repeating the above argument for each pole we have

$$\text{pr. v.} \int_{-\infty}^{\infty} f(x) dx = 2\pi i \sum \text{Res}(f(z)) + \pi i \sum \text{Res}^*$$

where $\sum \text{Res}^*$ is the sum of residues of $f(z)$ at its poles on the real axis.

And further we will explain this so since this goes to 0 as r goes to infinity because $fz = pz/qz$ is a rational function and degree qz -degree of pz is ≥ 2 we will get the same thing degree of qz -degree of $pz \geq 2$. Okay thus principal value of integral from -infinity to infinity of $fz dx = 2\pi i \sum \text{residue of } fz + \pi i$ because on the left integral from $-\pi i$ to πi so $+ \pi i * \text{residue of } fz \text{ at } z=a$.

Now if fz has a finite number of poles we have taken the case where fz has a simple pole at $z=a$ if there are more than 1 pole okay then we will find the residues at all the poles. Then we if fz has a finite number of simple poles on the real axis then repeating the above argument for each pole we will have here this expression this one will change or replace by $\pi i \sum \text{residue star}$ $\sum \text{residue star}$ is the term of the residues of fz at its poles on the real axis.

We showed this formula for a case of a simple pole at $z=a$ but there can be one such similarity on the real axis. So, we collect the we find out the residue at all the similarities on the real axis take their sum and multiply by πi . So this is what we do to evaluate the Cauchy principal value of the integral from -infinity to infinity of $fz dx$.

(Refer Slide Time: 43:07)

Example 2

Show that

$$\int_0^{\infty} \frac{\sin x}{x} dx = \frac{\pi}{2}.$$

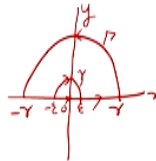

Let us consider the contour integral $\int_C \frac{e^{iz}}{z} dz$

We can write

$$\int_C \frac{e^{iz}}{z} dz = \int_{-\gamma}^{-\epsilon} \frac{e^{iz}}{z} dz + \int_{-\epsilon}^{-\gamma} \frac{e^{iz}}{z} dz + \int_{\gamma}^{\epsilon} \frac{e^{iz}}{z} dz + \int_{\epsilon}^{\gamma} \frac{e^{iz}}{z} dz$$

Let $f(z) = \frac{e^{iz}}{z}$. Then $f(z)$ is analytic inside and on C

By Cauchy integral theorem $\int_C \frac{e^{iz}}{z} dz = 0$

We have $\lim_{\epsilon \rightarrow 0} \int_C f(z) dz = -\pi i \operatorname{Res} f(z) = -\pi i$ because $\operatorname{Res} f(z) = 1$ at $z=0$

Thus, let $\gamma \rightarrow \infty$ and $\epsilon \rightarrow 0$ then

$$\lim_{\gamma \rightarrow \infty} \int_{-\gamma}^{-\epsilon} \frac{e^{iz}}{z} dz + \lim_{\gamma \rightarrow \infty} \left[\int_{-\epsilon}^{-\gamma} \frac{e^{iz}}{z} dz + \int_{\epsilon}^{\gamma} \frac{e^{iz}}{z} dz \right] - \pi i = 0$$

$= \lim_{\gamma \rightarrow \infty} \int_{-\gamma}^{-\epsilon} \frac{e^{iz}}{z} dz = 1$

Now let us consider the case of this integral $\int_0^{\infty} \frac{\sin x}{x} dx = \frac{\pi}{2}$ now this integral you can see is not of the type which we have discussed now okay because here the difference is not that of 2 units. Of course sin if you when you write the corresponding contour integral here e to the power $i z/z$ then $z=0$ which lies on the real axis the integrand will have a pole a simple pole.

But the other condition regarding $\int_{\gamma} f(z) dz$ to go to 0 that is not satisfied here. So, it is a another case another example where we are going to find the Cauchy principal value, we are going to find the integral of $\sin x / x$ over the interval 0 to infinity. So, what we do let us consider the corresponding contour integral and contour is this okay C is the contour we can write $\int_C e$ to the power $iz dz/z = \int_{\gamma} f(z) dz$ this is gamma.

This is small gamma $\int_{\gamma} e$ to the power $iz dz/z + \int_{-\gamma}^{-\epsilon} e$ to the power iz/z has a similarity $z=0$ so $-\gamma$ to $-\epsilon$ e to the power ix/x $dx + \int_{\gamma} e$ to the power iz/z $dz + \int_{\epsilon}^{\gamma} e$ to the power iz/z dz okay now let $fz=e$ to the power iz/z okay e to the power iz/z does not have any similarity in the contour okay c . So, by Cauchy integral theorem if you assume fz to be iz/z and fz is analytic inside and on C .

So, by Cauchy integral theorem $\int_C e$ to the power $iz/z=0$ let us recall the article from the article let us evaluate the $\int_{\gamma} \lim_{\epsilon \rightarrow 0} \int_{\gamma} f(z) dz = -\pi i$

residue at $z=a$ fz so let us follow that. So, we have limit ϵ tends to 0 $\int_{\gamma} f(z) dz = -\pi i$ residue of fz at $z=0$ okay and that is $-\pi i$ because residue of fz at $z=0$ is limit z tends to 0 z times fz fz is e to the power iz/z .

So, this is $=1$ okay this is $-\pi i$ so thus let r go to infinity and ϵ tends to 0 okay when we will get, we can show that $\int_{\gamma} e^{iz} dz/z$ goes to 0 as r goes to infinity okay so we will have limit tends to infinity $\int_{\gamma} e^{iz} dz/z +$ limit ϵ tends to 0, r tends to infinity we have $\int_{-r}^{-\epsilon} e^{ix}/x dx + \int_{\epsilon}^r e^{ix}/x dx$.

This should be here because we are moving along the real axis. So it should be x so this and $\int_{\gamma} e^{iz} dz/z$ we got $-\pi i$ this is $=0$ okay this is what we get okay first we shall show that this value $=0$.

(Refer Slide Time: 49:30)

Let us show that $\lim_{r \rightarrow \infty} \int_{\gamma} \frac{e^{iz}}{z} dz = 0$

$$\left| \frac{e^{iz}}{z} \right| = \left| \frac{e^{i(x+iy)}}{z} \right| = \left| \frac{e^{ix} \cdot e^{-y}}{r} \right| = \frac{e^{-y}}{r}$$

$$\left| \int_{\gamma} \frac{e^{iz}}{z} dz \right| \leq \int_0^{\pi} \frac{e^{-r \sin \theta}}{r} r d\theta$$

$z = r e^{i\theta}$
 $dz = r e^{i\theta} i d\theta$
 $|dz| = r d\theta$
 Jordan's inequality
 $\sin \theta \geq \frac{2\theta}{\pi}, \theta \in [0, \frac{\pi}{2}]$

$$= 2 \int_0^{\pi/2} e^{-r \sin \theta} d\theta$$

$$\leq 2 \int_0^{\pi/2} e^{-2r\theta/\pi} d\theta = \frac{\pi}{r} (1 - e^{-r}) \rightarrow 0, \text{ as } r \rightarrow \infty$$

Then

$$\text{p.v.} \int_{-\infty}^{\infty} \frac{e^{ix}}{x} dx = \pi i$$

$$\text{p.v.} \int_{-\infty}^{\infty} \frac{\cos x + i \sin x}{x} dx = \pi i \Rightarrow \text{p.v.} \int_{-\infty}^{\infty} \frac{\sin x}{x} dx = \pi$$

Since $\int_0^{\infty} \sin x dx$ is convergent, $\text{p.v.} \int_{-\infty}^{\infty} \frac{\sin x}{x} dx = \pi$

So, let us show this is $=0$ okay so mod e to the power iz/z along γ we have to find so e to the power $i(x+iy)/z$ and this is mod of e to the power ix e to the power $-y/r$ because along γ mod $z=r$. So, mod of e for $i=1$ this is e to the power $-r \sin \theta / r$ okay now $\int_{\gamma} e^{iz} dz/z$ mod of this is $\leq e$ to the power $-r \sin \theta / r$ and the mod of dz $dz=r$ e to the power $i \theta$ so dz is r e to the power $i \theta$ $i d\theta$.

So, $dz \text{ mod } = r d\theta$. So, we get $r d\theta$ here, so this r cancels now let us notice that by the property definite integral $\int_0^{\pi/2} \sin(\pi - \theta) d\theta = \int_0^{\pi/2} \sin \theta d\theta$ so this becomes $\int_0^{\pi/2} r \sin \theta d\theta$. Now there is an important result $\sin \theta \geq \frac{2}{\pi} \theta$ when θ belongs to 0 to $\pi/2$ this is called as Jordons inequality it is very easy to prove we can prove it by calculus Jordons inequality.

So, this is now $\leq 2 \int_0^{\pi/2} e^{-2r\theta/\pi} d\theta$ and now we can integrate easily. So, $e^{-2r\theta/\pi}$ so this is $= \pi$ times this 2 will cancel with this 2 and π/r we get $1 - e^{-r}$ limits are 0 to $\pi/2$ so we get $1 - e^{-r}$. Now if r goes to infinity e^{-r} goes to 0 and π/r goes to 0 . So, $0 \cdot 1 = 0$ so which goes to 0 as r goes to infinity. Okay this is how we prove this $= 0$.

Now what we have this becomes 0 so we will get this $= \pi i$ okay this is nothing but Cauchy principal value Cauchy principal value $= \pi i$ so we get the following. So, then principal value of $\int_{-\infty}^{\infty} e^{ix}/x dx = \pi i$ okay now you can put here $\cos x + i \sin x$ so $\int_{-\infty}^{\infty} \cos x + i \sin x / x dx$. Okay so the principal value of this $= \pi i$. This means that if you get real imaginary parts.

Then this is principal value of $\int_{-\infty}^{\infty} \sin x / x dx = \pi$ okay now we know that $\int_{-\infty}^{\infty} \sin x / x dx$ okay is a convergent integral it is a convergent integral therefore Cauchy principal value of $\int_{-\infty}^{\infty} \sin x / x dx$ is same as $\int_{-\infty}^{\infty} \sin x / x dx$. So, since okay this is convergent okay, we have \cos principal value $= \int_{-\infty}^{\infty} \sin x / x dx = \pi$.

Now $\sin x / x dx$ is an even function $\int_{-\infty}^{\infty} \sin x / x dx = 2 \int_0^{\infty} \sin x / x dx$ okay. So, since $\sin x / x$ is an even function we get $\int_0^{\infty} \sin x / x dx = \pi/2$ this is how we evaluate the integral. With this we come to the end of this lecture thank you very much for your attention.
