Lecture – 23
Evaluation of Real Integrals Using Residues - III

Hello friends. Welcome to my lecture on evaluation of real integrals using residues. Now here we are going to consider some special kind of real integrals where we need to take a different kind of contour, different from the ones which we have studied so far. The contour will depend on the problem. It changes from problem to problem. So let us see. We will now illustrate some, show some examples and there we shall see how some certain types of real integrals can be evaluated by making a suitable choice of contours other than those considered earlier.

(Refer Slide Time: 01:07)

Some Special Improper Real Integrals

We shall now illustrate by examples how certain types of real integrals can be evaluated by making a suitable choice of contours other than those considered earlier.

 IIT ROORKEE  NPTEL ONLINE COURSE

2

So let us consider this integral.

(Refer Slide Time: 01:15)

Example 1

Using

$$\int_0^{\infty} e^{-x^2} dx = \frac{\sqrt{\pi}}{2}, \checkmark$$

show that

$$\text{a) } \int_0^{\infty} e^{-x^2 \cos 2\alpha} \cos(x^2 \sin 2\alpha) dx = \frac{\sqrt{\pi}}{2} \cos \alpha;$$

$$\text{b) } \int_0^{\infty} e^{-x^2 \cos 2\alpha} \sin(x^2 \sin 2\alpha) dx = \frac{\sqrt{\pi}}{2} \sin \alpha;$$

$$\text{c) } \int_0^{\infty} \cos x^2 dx = \int_0^{\infty} \sin x^2 dx = \frac{\sqrt{\pi}}{2\sqrt{2}}.$$

3

Integral 0 to infinity e^{-x^2} dx where we know that by using gamma function, the value of this integral is $\sqrt{\pi}/2$. So using this value of integral 0 to infinity e^{-x^2} dx, let us find the value of the integral 0 to infinity $e^{-x^2 \cos 2\alpha} \cos x^2 \sin 2\alpha$ dx. And simultaneously, we will also get the value of integral 0 to infinity $e^{-x^2 \cos 2\alpha} \sin x^2 \sin 2\alpha$ dx.

So this is $\sqrt{\pi}/2 \cos \alpha$ and this is $\sqrt{\pi}/2 \sin \alpha$. And here when you will take $\alpha = \pi/4$, you will get integral $e^{-x^2 \cos \pi/2} \cos x^2 \sin \pi/2$ dx. $\cos \pi/2$ will be 0. So $e^{-x^2 \cdot 0}$ will be 1 and we will get $\cos x^2 \sin \pi/2$ is 1. So we will get integral 0 to infinity $\cos x^2$ here. And here when you take $\alpha = \pi/4$, you will similarly get $\sin x^2$.

So integral 0 to infinity $\cos x^2$ integral 0 to infinity $\sin x^2$ will be equal to $\sqrt{\pi}/2 \cos \pi/4 \sin \pi/4$ which each of the $\cos \pi/4 \sin \pi/4$ have value $1/\sqrt{2}$. So we will get $\sqrt{\pi}/2 \cdot 1/\sqrt{2}$. So by taking $\alpha = \pi/4$ in a and b, we get c. Now let us see how to get the value of a and b integrals by using residue calculus.

(Refer Slide Time: 02:47)

Solution: Let us consider the corresponding contour integral

$$\int_C e^{-z^2} dz$$

where contour C consists of the arc Γ of the circle $|z| = r$ from A to B , $(0 \leq \alpha \leq \frac{\pi}{4})$, the line BO and the line OA .

Since e^{-z^2} is analytic within and on the contour C , we have

$$\int_C e^{-z^2} dz = \int_0^r e^{-x^2} dx + \int_r^0 e^{-z^2} dz + \int_r^0 e^{-(\rho e^{i\alpha})^2} e^{i\alpha} d\rho = 0, \quad (1)$$

since on BO , $z = \rho e^{i\alpha}$, $0 \leq \rho \leq r$.

$$\frac{\sqrt{\pi}}{2} + \int_0^r e^{-(\rho^2 e^{2i\alpha})} e^{i\alpha} d\rho = 0$$

$$\frac{\sqrt{\pi}}{2} = \int_0^r e^{-(\rho^2 e^{2i\alpha})} e^{i\alpha} d\rho = \frac{\sqrt{\pi}}{2}$$

So let us consider the contour integral, integral over C e^{-z^2} where the contour C consists of the arc of the circle $|z|=r$ from A to B . So let us draw the contour. So this is origin, okay. Let me take this as A and let us say this is B , okay. So then where the contour C consists of the arc Γ of the circle $|z|=r$, this is Γ , okay, arc of the circle. $|z|=r$ from A to B , $0 \leq \alpha \leq \pi/4$.

So α lies between 0 and $\pi/4$. The line BO and the line OA , this line OA and the line BO , okay. So this is $0, x, y$. So our contour is integral, our contour is the line OA , the arc Γ and the line BO , okay. Now e^{-z^2} is an analytic function within and on this contour C . So we have integral over C $e^{-z^2} dz = \int_0^r e^{-x^2} dx + \int_r^0 e^{-z^2} dz + \int_r^0 e^{-(\rho e^{i\alpha})^2} e^{i\alpha} d\rho = 0$. Now you see this AB is the arc of the circle with $|z|=r$. So $OA=r$.

So along OA , $z=x$ and therefore, we have integral 0 to r $e^{-x^2} dx$. Then integral along Γ $e^{-z^2} dz$ and then integral from r to 0 , we are coming from B to O , so integral from r to 0 . Now $z=\rho e^{i\alpha}$. Along BO , $z=\rho e^{i\alpha}$ where ρ varies from r to 0 . So we get $e^{-\rho^2 e^{2i\alpha}}$ $e^{i\alpha} d\rho$.

Every point z on the segment OB has argument α , okay. And let us say magnitude ρ , okay. So $z=\rho e^{i\alpha}$ we put here and then $dz=e^{i\alpha} d\rho$ because α is

constant, okay. So since on BO, $z = \rho e^{i\alpha}$ and ρ varies from 0 to r . We are coming from B to 0, so we are writing r to 0, okay.

(Refer Slide Time: 05:24)

Now,

$$\left| \int_{\Gamma} e^{-z^2} dz \right| \leq r \int_0^{\alpha} |e^{-r^2 e^{2i\theta}}| |ie^{i\theta}| d\theta \quad \text{where } z = re^{i\theta}$$

$$= r \int_0^{\alpha} e^{-r^2 \cos 2\theta} d\theta$$

$$= \frac{1}{2} r \int_{\beta}^{\frac{\pi}{2}} e^{-r^2 \sin \phi} d\phi$$

$$< \frac{1}{2} r \int_{\beta}^{\frac{\pi}{2}} e^{-2r^2 \phi / \pi} d\phi$$

where $\phi = \frac{\pi}{2} - 2\theta$ and $\beta = \frac{\pi}{2} - 2\alpha \geq 0$, since $0 \leq \alpha \leq \frac{\pi}{4}$.

Handwritten notes on the slide:

- $\text{Am } \phi = \frac{2\phi}{\pi}, \phi \in [\frac{\pi}{2}, \pi]$
- $\int_0^{\alpha} e^{-r^2 \cos 2\theta} d\theta = \int_{\frac{\pi}{2}}^{\pi} e^{-r^2 \sin \phi} \frac{1}{2} d\phi$
- $\left| e^{-r^2 (\cos 2\theta + i \sin 2\theta)} \right| = e^{-r^2 \cos 2\theta} / e^{-r^2 \sin 2\theta}$
- $= e^{-r^2 \cos 2\theta}$
- Let $\phi = \frac{\pi}{2} - 2\theta$
- $\sin \phi = \sin(\frac{\pi}{2} - 2\theta) = \cos 2\theta$
- $d\phi = -2d\theta$
- When $\theta = 0$, $\phi = \frac{\pi}{2}$
- When $\theta = \alpha$, $\phi = \frac{\pi}{2} - 2\alpha = \beta$

Now mod of, now let us find the value of the integral along gamma, the semi, the part of the circle, mod of $z=r$. So integral over gamma e to the power $-z$ square dz is less than or equal to r , let us put $z=rei$ theta. Any point here, on the arc, okay, I can write $z=re$ to the power i theta, okay. So $z=rei$ theta, when we put, we get e to the power $-r$ square e to the power $2i$ theta and then $dz=r3$ to the power i theta*id theta, okay.

So r is constant, it comes here. Then 0 to alpha mod of e to the power $-r$ square e to the power $2i$ theta, okay. e to the power $-r$ square, e to the power $2i$ theta is $\cos 2\theta + i \sin 2\theta$. So mod of this= e to the power $-r$ square $\cos 2\theta$ because mod of e to the power $-ir$ square $\sin 2\theta = 1$, okay. So this is e to the power $-r$ square $\cos 2\theta$ and then mod of i and mod of e to power i theta is 1, so we get this, okay.

Now here, we put first $\phi = \pi/2 - 2\theta$, okay. In this integral, let us take $\phi = \pi/2 - 2\theta$, okay. Then what do you get? $\sin \phi = \sin \pi/2 - 2\theta$ which gives you $\cos 2\theta$. So for $\cos 2\theta$, we write $\sin \phi$ and you also notice that $d\phi = -2d\theta$, okay. Theta vary from 0 to alpha, okay. So when $\theta = 0$, $\phi = \pi/2$ and when $\theta = \alpha$, we get $\phi = \pi/2 - 2\alpha$, okay. $\pi/2 - 2\alpha$ we denote by beta, okay.

So what do we get? Integral 0 to alpha $e^{-r^2 \cos 2\theta} d\theta$, will be replaced by; for 0, we get the limit $\pi/2$; for alpha, we get the limit beta, $e^{-r^2 \cos 2\theta}$ becomes $\sin \phi$ and $d\theta$ becomes $-d\phi/2$. So this is $1/2$ and the limits of integration can be changed because of this - sign. So we get beta $\pi/2$ $e^{-r^2 \sin \phi} d\phi$, okay.

And r was already there outside. So we get $1/2r$ integral over beta to $\pi/2$ $e^{-r^2 \sin \phi} d\phi$. Since let us look at this. Alpha lies between 0 and $\pi/4$; therefore, 2α lies between 0 and $\pi/2$. So beta is greater than or equal to 0. Because of this condition, beta is greater than or equal to 0.

Beta is greater than or equal to 0, so integral over beta to $\pi/2$ we have. And we know that as we have seen earlier $\sin \phi$ is greater than or equal to $2\phi/\pi$, okay when ϕ belongs to the interval 0 to $\pi/2$, Jordan inequality. So we have put here, for $\sin \phi$, we put $2\phi/\pi$, so we get $e^{-2r^2 \phi/\pi}$, okay. So from here, we come to this, okay.

(Refer Slide Time: 09:45)

$$\left| \int_{\Gamma} e^{-z^2} dz \right| < \frac{1}{2} r \left(\frac{e^{-2r^2 \phi/\pi}}{-2r^2/\pi} \right)_{\beta}^{\pi/2}$$

$$= \frac{1}{2} r \frac{\pi}{2r^2} (e^{-2r^2 \beta/\pi} - e^{-r^2}) = \frac{\pi}{4r} (e^{-2r^2 \beta/\pi} - e^{-r^2})$$

Hence as $r \rightarrow \infty$, we have

$$\int_{\Gamma} e^{-z^2} dz \rightarrow 0.$$

In (1), let $r \rightarrow \infty$, then

$$\int_0^{\infty} e^{-x^2} dx = \frac{\sqrt{\pi}}{2}$$

Now mod of integral over gamma $e^{-z^2} dz$ is less than, okay, so we have just integrated here $e^{-2r^2 \phi/\pi}$, when you integrate, you get $e^{-2r^2 \phi/\pi}$ $-2r^2 \phi/\pi$, okay. Because we are integrating with respect to ϕ . And $1/2r$ is

outside, so we get $1/2r$ and then we get $\pi/2r$ square from here and then we get, we put the upper and lower limits, we get e to the power $-2r$ square $\beta/\pi - e$ to the power $-r$ square.

Now when r goes to infinity, what will happen? What will happen here when r goes to infinity? This is, when r will cancel, we get $\pi/4r$, okay, $\pi/4re$ to the power $-2r$ square β/π , okay, $-e$ to the power $-r$ square, okay. And β as you have seen, β is greater than or equal to 0, okay. So even if $\beta=0$, when $\beta=0$, this becomes 1. So $1-e$ to the power $-r$ square, we have. And when r goes to infinity, this goes to 0, okay.

This is suppose 1. Then $1-0$ is 1 and then $1/r$ here is there. So $1/r$ goes to 0 and therefore, this goes to 0 as r goes to infinity. If $\beta>0$, then this goes to 0, this goes to 0 and this also goes to 0, okay. So r goes to infinity, integral over γ e to the power $-z$ square dz goes to 0. Now in the equation 1, let us go to the equation 1. So in this equation as r goes to infinity, what happens? This becomes integral 0 to infinity e to the power $-x$ square dx and this goes to 0 and we get here infinity to 0, this quantity, okay.

Let us see what is this, okay. So when r goes to infinity, this is integral 0 to infinity e to the power $-x$ square dx , okay. This quantity becomes integral 0 to infinity e to the power $-x$ square dx . This is known to us. It is $\sqrt{\pi}/2$. So what do we get? This we are using. So this becomes, this is $\sqrt{\pi}/2$, okay. So $\sqrt{\pi}/2$ and this goes to 0 and then we have infinity to 0 e to the power $-\rho$ square e to the power $2i\alpha * e$ to the power $i\alpha d\rho=0$, okay.

So when it goes to the other side, the limits will change to 0 to infinity. So this becomes 0 to infinity e to the power $-\rho$ square e to the power $2i\alpha * e$ to the power $i\alpha d\rho=\sqrt{\pi}/2$. And then you put e to the power $2i\alpha$ as $\cos 2\alpha + i \sin 2\alpha$ and you put here for e to the power $i\alpha$, you put $\cos \alpha + i \sin \alpha$. So we get this, okay.

(Refer Slide Time: 13:09)

$$\int_0^{\infty} e^{-\rho^2(\cos 2\alpha + i \sin 2\alpha)} d\rho = \frac{\sqrt{\pi}}{2} e^{-i\alpha} \checkmark$$

$$\int_0^{\infty} e^{-\rho^2 \cos 2\alpha} \{ \cos(\rho^2 \sin 2\alpha) - i \sin(\rho^2 \sin 2\alpha) \} d\rho = \frac{\sqrt{\pi}}{2} e^{-i\alpha}$$

$= \frac{\sqrt{\pi}}{2} (\cos \alpha - i \sin \alpha)$

Equating real and imaginary parts, we get

$$\int_0^{\infty} e^{-\rho^2 \cos 2\alpha} \cos(\rho^2 \sin 2\alpha) d\rho = \frac{\sqrt{\pi}}{2} \cos \alpha \checkmark$$

$$\int_0^{\infty} e^{-\rho^2 \cos 2\alpha} i \sin(\rho^2 \sin 2\alpha) d\rho = \frac{\sqrt{\pi}}{2} \sin \alpha \checkmark$$

 IIT BOMBAY
  NPTEL ONLINE EDUCATION COURSE

7

So e to the power i alpha we bring to the right side and then integral 0 to infinity e to the power -rho square cos 2alpha+i sin 2alpha d rho=root pi/2 e to the power -i alpha. This e to the power i alpha which was here, comes here because it is independent of rho. So then 0 to infinity e to the power -rho square cos 2 alpha*e to the power -i rho square sin 2alpha, that is cos rho square sin 2alpha-i sin rho square sin 2 alpha d rho=this.

Now let us equate here real and imaginary parts. This is root pi/2 cos alpha-i sin alpha. So then integral 0 to infinity e to the power -rho square cos 2alpha cos rho square sin 2alpha d rho=root pi/2 cos alpha and 0 to infinity e to the power -rho square cos 2 alpha sin rho square sin 2alpha d rho=root pi/2 sin alpha. So this proves part A and B and as I said, part C can be obtained from here by taking alpha=pi/4, okay.

(Refer Slide Time: 14:23)

Example 2

Integrating

$$\int_C e^{-z^2} dz,$$

where C is the boundary of the rectangle with vertices at $-a$, a , $a + ib$, $-a + ib$, and letting $a \rightarrow \infty$, evaluate the integral

$$\int_0^\infty e^{-x^2} \cos(2bx) dx.$$

It is given that

$$\int_0^\infty e^{-x^2} dx = \frac{\sqrt{\pi}}{2}.$$

So we get part C. Now integral over C e to the power $-z$ square dz , where C is the boundary of the rectangle with vertices at $-a$, a , $a+ib$, $-a+ib$ and letting a tends to infinity, let us evaluate this integral. We are given that this is equal $\sqrt{\pi}/2$. So you can see here we have this contour. This is $-a$, 0 . Let us take a here and then this is $a+ib$ and we have $-a+ib$ here, okay. So let us take this segment $-a$ to a as C_1 . This segment a to $a+ib$ as C_2 . From $a+ib$ to $-a+ib$ is C_3 and $-a+ib$ to $-a$ as C_4 , okay.

So our contour C consists of 4 parts, okay. The 4 parts are C_1 , C_2 , C_3 , C_4 , okay. So we will evaluate the integral over C e to the power $-z$ square dz along all these 4 parts, okay to evaluate the integral over C e to the power $-z$ square dz which is equal to 0 because we see is a simple closed curve and e to the power $-z$ square is analytic in the whole complex plane. So it is analytic inside and on this contour C , okay. So let us find this integral.

(Refer Slide Time: 16:07)

Solution: Let $I = \int_C f(z) dz$, where $f(z) = e^{-z^2}$ and C is as given in Fig.

So integral over C $f(z) dz$ where $f(z) = e^{-z^2}$ and C is given here, C as I draw there. Let us draw again here, okay. So what we do is.

(Refer Slide Time: 16:43)

The integrand is analytic inside and on C . Therefore, by the Cauchy Integral Theorem

$$\int_C f(z) dz = \int_{C_1} f(z) dz + \int_{C_2} f(z) dz + \int_{C_3} f(z) dz + \int_{C_4} f(z) dz = 0. \quad (2)$$

For evaluation along C_1 , we have $z = x$, $-a \leq x \leq a$. Therefore,

$$\int_{C_1} f(z) dz = \int_{-a}^a e^{-x^2} dx = 2 \int_0^a e^{-x^2} dx.$$

Letting $a \rightarrow \infty$, we get

$$\int_{C_1} f(z) dz = 2 \int_0^\infty e^{-x^2} dx = \sqrt{\pi}. \quad (3)$$

The integrand is analytic inside and on C . Therefore, by Cauchy integral theorem, integral over C $f(z) dz =$ integral over $C_1 +$ integral over $C_2 +$ integral over $C_3 +$ integral over $C_4 = 0$, okay. Now for evaluation along C_1 , okay. Let us draw here now. Now you can see. When we want to integrate along C_1 , the line segment from $-a$ to a lies on the real axis. Therefore, for z , we shall write x , okay and $f(z)$ is e to the power $-z$ square.

So we now write x for z . So e to the power $-x$ square dx and x varies from $-a$ to a . Now e to the

power $-x$ square is an even function of x . So it is 2 times 0 to a e to the power $-x$ square dx . And when a goes to infinity, the limit of this is $2 \times \int_0^\infty e^{-x^2} dx$. So when a goes to infinity, this becomes $2 \times \sqrt{\pi}/2$, that is $\sqrt{\pi}$, okay. Now let us integrate along C_2 .

(Refer Slide Time: 18:19)

For evaluating along C_2 , we have $z = a + iy, 0 \leq y \leq b$. Therefore,

$$\int_{C_2} f(z) dz = \int_0^b e^{-(a+iy)^2} i dy = i \int_0^b e^{-(a^2-y^2)} e^{-2aiy} dy. \quad (4)$$

For evaluating along C_3 , we have $z = x + ib, x$ varies from a to $-a$. Therefore,

$$\int_{C_3} f(z) dz = - \int_a^{-a} e^{-(x+ib)^2} dx = - \int_a^{-a} e^{-(x^2-b^2)} e^{-2ibx} dx. \quad (5)$$

For evaluating along C_4 , we have $z = -a + iy, y$ varies from b to 0 . Therefore,

$$\int_{C_4} f(z) dz = - \int_b^0 e^{-(-a+iy)^2} i dy = -i \int_b^0 e^{-(a^2-y^2)} e^{2iaiy} dy. \quad (6)$$

(Handwritten note in red: $\int_{C_2} + \int_{C_3} + \int_{C_4} = -i \left[\int_0^b \frac{e^{-(a^2-y^2)}}{(a^2-y^2)} \left(e^{2iaiy} - e^{-2iaiy} \right) dy \right] = -i \int_0^b \frac{e^{-(a^2-y^2)}}{(a^2-y^2)} (2i \sin 2ay) dy = \int_0^b \frac{e^{-(a^2-y^2)}}{(a^2-y^2)} \sin 2ay dy$)

11

So for evaluating along C_2 , now let us look at this. Along C_2 , x remains constant. $x=a$, y varies from 0 to b . So we can take any point z here. The z can be written as $a+iy$, okay, where y varies from 0 to b along C_2 , okay. So on C_2 , we have this. So let us use this $z=a+ib$, y varies from 0 to b , then integral over C_2 $f(z)dz = \int_0^b f(z) \frac{dz}{dy} dy$. fz is e to the power $-z$ square. So e to the power $-a+iy$ whole square. dz is idy , okay.

So idy we put and then e to the power $-a+iy$ whole square is a square $-y$ square $+2iaiy$, so we get e to the power $-a$ square $-y$ square $\times e$ to the power $-2aiy$ and then dy . This i we have kept outside, okay. For evaluating along C_3 , now let us look at C_3 . Along C_3 , you notice that this y is fixed, okay, $y=b$, okay. x varies, x varies from a to $-a$, okay. So on C_3 , we will write z as $x+ib$, okay, where x varies from a to $-a$, okay.

So you put $x+ib$, x varies from a to $-a$. So along C_3 , we have, now from a to $-a$, we can make it from $-a$ to a , but we have to put negative sign here. So $-\int_{-a}^a e$ to the power $-z$ square. So e to the power $-x+ib$ whole square and $dz=dx$. So we put dx here. So $-\int_{-a}^a$

to a, you can now square this, so then x square-b square and then we get e to the power $-2ibxdx$. And when we integrate along C_4 , along C_4 you notice again that y is fixed, okay, no y varies, x is fixed. $x=-a$, okay.

So along C_4 , $z=-a+iy$ where y varies from b to 0, okay. So we get $z=-a+iy$, y varies from b to 0 and therefore, integral over C_4 $f(z)dz=-$ integral over 0 to b. It was from b to 0 when we want to make it 0 to b, we put negative sign. So -0 to b e to the power $-z$ square, z is $-a+iy$ whole square. $dz=idy$, okay. So this is $-i$ and then integral 0 to b e to the power $-a$ square-y square then e to the power $2iaydy$, okay.

(Refer Slide Time: 21:20)

Combining Equations (4) and (6), we obtain

$$\begin{aligned} I^* &= \int_{C_2} f(z) dz + \int_{C_4} f(z) dz \\ &= -i \int_0^b e^{-(a^2-y^2)} [e^{2aiy} - e^{-2aiy}] dy \\ &= 2 \int_0^b e^{-(a^2-y^2)} \sin(2ay) dy. \end{aligned}$$

Now, $|I^*| \leq 2 \int_0^b \frac{e^{-(a^2-y^2)}}{e^{-a^2+y^2}} |\sin(2ay)| |dy| \leq 2be^{-a^2+b^2} \rightarrow 0$ as $a \rightarrow \infty$
 since, $e^{-(a^2-y^2)} = e^{-a^2+y^2} \leq e^{-a^2+b^2}$ and $|\sin(2ay)| \leq 1$.

FT MOOTWEE NPTEL ONLINE CERTIFICATION COURSE 12

Now let us see combine equations 4 and 6, okay. 4 is this one, okay. 4 is this and 6 is this. When you combine C_2 and C_4 , what do you get? You notice that e to the power $-ia$ square-y square and this is same here, okay. So let me combine integral over C_2 +integral over C_4 $f(z)dz$, this gives you $-i$ *integral over 0 to b e to the power $-a$ square-y square and e to the power $2iay$ and then here $-e$ to the power $-2aiydy$, okay.

So this is $-i$ *integral over 0 to b e to the power $-a$ square-y square. And this $2i$ *sin $2ay$, okay. So dy. So this is what we put here, okay. This is $2*$, I square becomes -1 , so $2*0$ to b e to the power $-a$ square-y square sin $2aydy$. Now let us estimate the value of i^* . So mod of i^* is less than or equal to $2*0$ to b e to the power $-a$ square-y square. This is positive quantity. Then mod of sin

2ay, mod of sin theta is less than or equal to 1.

So this is less than or equal to $2 \cdot b \cdot e$ to the power $-a^2 + b^2$, okay. Now how we get this? You can see here. Sin this quantity e to the power $-a^2 - y^2$ is e to the power $-a^2 + y^2$, okay. So e to the power y^2 varies from 0 to b and e to the power y^2 is an increasing function. So e to the power y^2 will be less than or equal to e to the power b^2 . So this quantity is less than or equal to $2b \cdot e^{b^2 - a^2}$.

And therefore, this is less than or equal to $2b \cdot e^{b^2 - a^2}$, okay. So $2b \cdot e^{b^2 - a^2}$ goes to 0 as a goes to infinity, okay. So this quantity goes to 0 as a goes to infinity. So $C_2 + C_4$, okay, when a goes to infinity go to 0. Now what is left? We are left with integral along C_1 . Integral along C_1 we have already found. It is $\sqrt{\pi}$, okay. So integral along C_3 , okay. C_3 is this, okay. Let us concentrate on this.

(Refer Slide Time: 24:28)

From Equation (2), on letting $a \rightarrow \infty$, we obtain

$$\sqrt{\pi} - \int_{-\infty}^{\infty} e^{-(x^2 - b^2)} e^{-2ibx} dx = 0$$

$$\int_{-\infty}^{\infty} e^{-(x^2 - b^2)} (\cos(2bx) - i \sin(2bx)) dx = \sqrt{\pi}.$$

Comparing the real part on both sides, we get

$$\int_{-\infty}^{\infty} e^{-(x^2 - b^2)} \cos(2bx) dx = \sqrt{\pi}$$

$$\int_0^{\infty} e^{-x^2} \cos(2bx) dx = \frac{\sqrt{\pi}}{2} e^{-b^2}.$$

Handwritten notes in red:
 $\int_{-\infty}^{\infty} e^{-(x^2 - b^2)} \sin(2bx) dx = 0$
or $\int_{-\infty}^{\infty} e^{-x^2} \sin(2bx) dx = 0$

ET ROOFTOP
 NPTEL ONLINE
 COURSE

13

So we get now $\sqrt{\pi}$ -integral, okay. When a goes to infinity, this becomes $-\infty$ to ∞ , this quantity, okay. So $\sqrt{\pi}$ -this, okay. So $\sqrt{\pi}$ -integral over $-\infty$ to ∞ $e^{-(x^2 - y^2)} e^{-2ibx} dx = 0$ and we can put it as $\cos 2bx - i \sin 2bx$. So $-\infty$ to ∞ $e^{-(x^2 - y^2)} \cos 2bx - i \sin 2bx dx = \sqrt{\pi}$.

Now comparing real part on both sides because we want to evaluate the value of integral over

$-\infty$ to ∞ e to the power $-x^2 - y^2 \cos 2bx$. We ultimately want to get this. So we just need to evaluate the, compare the real part. So $-\infty$ to ∞ e to the power $-x^2 - b^2 \cos 2bx dx = \sqrt{\pi}$, okay. And these are real quantities. So if you, imaginary part if you look at, the imaginary part will have value 0, integral over $-\infty$ to ∞ e to the power $-x^2 - b^2 \sin 2bx dx$.

This will be equal to 0, okay. Or we can say integral over $-\infty$ to ∞ e to the power $-x^2 \sin 2bx dx = 0$. You can divide this equation by e to the power b^2 , okay. And this has to happen because this is an even function, e to the power $-x^2$ is an even function. $\sin 2bx$ is an odd function. So its value over $-\infty$ to ∞ has to be 0. So that is verified. Now this is equal to $\sqrt{\pi}$.

So we can now write it as e to the power $-x^2 * e$ to the power b^2 . This is the power b^2 square we can take to the other side and this is $\sqrt{\pi} * e$ to the power $-y^2$ now. e to the power $-x^2 \cos 2bx$ is an even function. So we can make it $2 * 0$ to ∞ , okay. So 0 to ∞ e to the power $-x^2 \cos 2bx dx$ is $\sqrt{\pi} * e$ to the power $-b^2/2$, okay. So with that I come to the end of this lecture. Thank you very much for your attention.
