**Lecture – 28**  
**Conformal Mapping - I**

Hello friends. Welcome to my lecture on conformal mappings. A complex linear function is defined as a function of the form  $fz = az + b$  where  $a$  and  $b$  are complex constants.

(Refer Slide Time: 00:36)

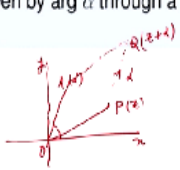

**Geometrical signification of the transformations**

**1.  $w = z + \alpha$  (Translation)**

The translation

$$w = z + \alpha$$

may be regarded as a translation in the direction given by  $\arg \alpha$  through a distance equal to  $|\alpha|$ .

**Linear Mappings**

A complex linear function is defined as a function of the form

$$f(z) = az + b,$$

where  $a$  and  $b$  are complex constants.

$f(z) = \zeta + b$  where  $\zeta = az$

 IIT ROORKEE

 NPTEL ONLINE CERTIFICATION COURSE

2

If you look at this function  $fz=az+b$ , then it consists of 2 transformations. The 2 transformations are, first transformation is the translation.

(Refer Slide Time: 00:54)

**2.  $w = \beta z$  (Resultant of magnification and rotation)**

The transformation  $w = \beta z$  is the resultant of a rotation and a magnification. If  $|\beta| = 1$ , then there will be only rotation and if  $\beta$  is real and positive, there will be only magnification.

$\angle PO P' = \angle AOB = \arg$   
 $OP' = OA \cdot OP$   
 $|w| = |\beta| |z| = |z|$  if  $|\beta| = 1$   
 If  $\beta > 0$  then  $\arg \beta = 0$

IT ROADS  
NPTEL ONLINE  
CERTIFICATION COURSE

And the next transformation is the resultant of magnification and rotation. So let us first discuss the translation, okay. You can see this  $fz=az+b$  is actually a composition of 2 transformations. One is  $w=z+\alpha$ . The other one is  $w=\beta z$ . So let us see what is the geometrical significant of  $w=z+\alpha$ . In the complex  $z$  plane, let us say  $P$  and  $A$  represent the complex numbers  $z$  and  $\alpha$  where  $\alpha$  is fixed,  $z$  is a variable point.

Let us join them to the origin, okay. And then we complete the parallelogram  $OPQA$ , okay. Then this vector  $PQ$ , okay. The vector  $PQ$  represents the complex numbers  $\alpha$  and so this  $Q$  becomes  $z+\alpha$ , okay. So you can see that this transformation  $w=z+\alpha$  is actually a translation of the point  $P$  in the direction of the argument of  $\alpha$  through a distance  $\text{mod of } \alpha$ , okay.

This is the angle that the vector  $OA$  makes with the  $x$  axis. This is argument of  $\alpha$ , okay. So this  $OA$  is parallel to  $PQ$ , and therefore, we have to move the point  $P$  to get to the point  $Q$ . If we move  $P$  in the direction of the argument of  $\alpha$  and through a magnitude= $\text{mod of } \alpha$  because the magnitude of  $PQ=\alpha$ .

So we can say that the transformation  $w=z+\alpha$  is regarded as a translation in the direction given by argument of  $\alpha$  through a distance equal to mod of  $\alpha$  and when we look at the transformation  $w=\beta z$ , suppose we have this point P here and then we the complex numbers  $\beta$ .  $\beta$  is represented by the point A. P represents the complex numbers  $z$ .

Then P dash, okay, P dash represents  $w$ ,  $w=\beta z$  where the angle P dash OP, okay, the angle POP dash=angle AOB, which is the argument of  $\beta$ . Moreover that you can see from  $w=\beta z$ , that is  $OP \text{ dash} = \text{mod of } OA * OP$ . So  $OA * OP$ . That is to get to the point P dash, we have to turn the vector OP anticlockwise through an argument of  $\beta$  and magnify or contract the vector OP by the magnitude of  $\beta$  to get to the point P dash.

So we can say that  $w=\beta z$  is the resultant of a rotation, we have to rotate the vector OP through argument of  $\beta$  and then magnify, okay, this vector OP by mod of  $\beta$  times to get the vector OP dash. So it is a resultant of rotation and magnification. Now in case mod of  $\beta=1$ , then we can see mod of  $w=\text{mod of } \beta * \text{mod of } z$ , okay. So if mod  $\beta=1$ , this will be equal to mod of  $z$ , then there will be no magnification, okay.

The length of OP and the or you can say the magnitude of OP will be same as the magnitude of OP dash, so there will be only rotation. And if  $\beta$  is real and positive, then argument of  $\beta=0$ . If  $\beta>0$ , then argument of  $\beta=0$ , so there will be no rotation. There will be only magnification. The vector OP will simply be, will only be magnified. There will be no rotation in this case.

**(Refer Slide Time: 06:00)**

### 3. $w = \frac{1}{z}$ (Resultant of inversions in the real axis and in the unit circle)

Let  $w = \frac{1}{z}$  then

$$R = \frac{1}{r} \text{ and } \phi = -\theta$$

$$\begin{aligned} Re^{i\phi} &= \frac{1}{re^{i\theta}} \\ &= \frac{1}{r} e^{-i\theta} \\ R &= \frac{1}{r}, \phi = -\theta \end{aligned}$$

if we take

$$w = R e^{i\phi} \text{ and } z = r e^{i\theta}$$

Hence the transformation

$$w = \frac{1}{z}$$

is an inversion with respect to the unit circle combined with a reflection in the real axis.

Now let us consider the reciprocal function  $w=1/z$ , okay. It is the result of inversions in the real axis and the unit circle. So let us take  $w=1/z$  where  $w$  is  $Re^{i\phi}$  and  $z=re^{i\theta}$ , then what will happen?  $w=1/z$  will give us  $Re^{i\phi}=1/z$ . So  $1/re^{i\theta}$  to the power  $i\theta$  and which is equal to  $1/re^{i\theta}$  to the power  $-i\theta$ . So  $R$  will be equal to, equating absolute values,  $R=1/r$  and equating arguments, we get  $\phi=-\theta$ . So  $R$  is  $1/r$  and  $\phi=-\theta$ . Now let us show that how  $w=1/z$  gives us an inversion with respect to the unit circle combined with the reflection in the real axis.

(Refer Slide Time: 06:52)

Two points P and Q are called inverse points with respect to a circle with centre O and radius  $r$  if

$$OP \cdot OQ = r^2$$

Let  $OP = r$  and  $OQ = \frac{1}{r}$   
 $\angle POQ = \theta$

From  $\triangle OQA$   
 $\frac{OA}{OQ} = \sin \theta$   
 $\Rightarrow OA = \sin \theta$

From  $\triangle OPA$  we have  
 $\frac{OA}{OP} = \sin \theta$   
 $\Rightarrow OP = OA \csc \theta = \frac{1}{\sin \theta}$

Now,  $OA \cdot OP = (\sin \theta) \left( \frac{1}{\sin \theta} \right) = 1$   
 Therefore A and P are inverse points with respect to  $|z|=1$ .  
 The we consider the reflection of A in the real axis & we get  $P^*$

Let  $OP = r$  and  $OQ = \frac{1}{r}$   
 $\angle POQ = \theta$

Let  $\angle OQA = \alpha$   
 Then  $\angle OPA = \alpha$

From  $\triangle OQA$   
 $\frac{OA}{OQ} = \sin \alpha$   
 $\Rightarrow OA = \sin \alpha$

From  $\triangle OPA$  we have  
 $\frac{OA}{OP} = \sin \alpha$   
 $\Rightarrow OP = OA \csc \alpha = \frac{1}{\sin \alpha}$

Now,  $OA \cdot OP = (\sin \alpha) \left( \frac{1}{\sin \alpha} \right) = 1$   
 Therefore A and P are inverse points with respect to  $|z|=1$ .  
 The we consider the reflection of A in the real axis & we get  $P^*$

Let  $OP = r$  and  $OQ = \frac{1}{r}$   
 $\angle POQ = \theta$

Let  $\angle OQA = \alpha$   
 Then  $\angle OPA = \alpha$

From  $\triangle OQA$   
 $\frac{OA}{OQ} = \sin \alpha$   
 $\Rightarrow OA = \sin \alpha$

From  $\triangle OPA$  we have  
 $\frac{OA}{OP} = \sin \alpha$   
 $\Rightarrow OP = OA \csc \alpha = \frac{1}{\sin \alpha}$

Now,  $OA \cdot OP = (\sin \alpha) \left( \frac{1}{\sin \alpha} \right) = 1$   
 Therefore A and P are inverse points with respect to  $|z|=1$ .  
 The we consider the reflection of A in the real axis & we get  $P^*$

So let us look at this figure. Let us consider this unit circle. Suppose we have P point here. This is P, okay.  $OP=r$  and argument of, this P represents the complex numbers  $z$ . So this is mod of  $z$ . An argument of  $z=\theta$ , okay. So this angle is  $\theta$ . Let us drop the tangents from this point P on

the circle, okay. Say the point of contacts are Q and R, okay. So join Q to R, okay, like this and then join Q to the origin and R to origin.

Then this is mod of  $z=1$ . So  $OQ=OR=1$ . Let me call this point of intersection as A, okay. We will show that P and A are inverse points with respect to the unit circle, okay. So we will show that  $OA \cdot OP = \text{radius of the circle square}$ , that is  $1 \text{ square} = 1$ , okay. So let us see how we define the inverse points with respect to a circle? 2 points P and Q are called inverse points with respect to a circle with center say C and radius r if  $CP \cdot CQ = r \text{ square}$ .

So let us say we have this circle of radius r. This is center. Radius of the circle is r. Suppose P is here, Q is here, okay. Then  $CP \cdot CQ$ , should be equal to r square. So here we were going to show that A and P are inverse points with respect to the unit circle. Therefore, we have to show that  $OP \cdot OA = 1$ , okay. Now from the construction, it is clear that  $PQ=PR$ , length of the 2 tangents are same, okay.

And moreover,  $OQ=OR=1$  because the radius of the circle OQ and OR are the radius of the circle which is 1. Now we also notice that this angle, the angle  $OQP = \text{angle } ORQ = \pi/2$ . Because PQ is tangent and OQ is radius. Similarly, PR is tangent and OR is radius, okay. Now by SAS criterion, okay,  $PQ=PR$ ,  $OQ=OR$ , the angle between OQ and QP that is, is  $\pi/2$  and angle between OR and PR is also  $\pi/2$ .

So angle  $OQP = \text{angle } ORP$ . So by SAS criterion, triangles OQP and ORP are congruent. And therefore, this angle, okay, OPQ is same as the angle OPR, okay. Hence angle OPQ is same as angle OPR. Furthermore, the angle  $OAQ = \text{angle } OAR = \pi/2$ , okay. Now let us consider the triangle OQP, okay. So let us consider this, let us say this angle is, suppose I take it as say alpha, okay.

Let us say angle  $OQA = \alpha$ , okay. Then because OQP is  $\pi/2$ , so AQP is  $\pi/2 - \alpha$ . And this angle is  $\pi/2$ , so this angle is also alpha, okay. So then angle  $OPQ = \alpha$ . Now let us consider the triangle OQP. From the triangle OQP, we have  $OQ/OP = \sin \alpha$ . And therefore,  $OP = OQ \csc \alpha$ . But  $OQ=1$ , so this is  $\csc \alpha$ , okay. Now let us consider the triangle OQA. From

triangle OQA, what do we notice?

$OA/OQ$ , okay,  $=\sin \alpha$ . So this gives you  $OA=\sin \alpha$ , okay. Now  $OA \cdot OP$ , we can see is equal to  $\sin \alpha \cdot \operatorname{cosec} \alpha$  and therefore, it is equal to 1. So  $OA \cdot OP=1$  and therefore, A and P are inverse points with respect to the unit circle, with respect to  $\operatorname{mod} z=1$ , okay. Now what we do? Let us consider the reflection of this point A, okay, in the real axis. So this is your point  $P^*$ , okay.

And this  $P^*$  is obtained by reflecting the point A in the real axis. So  $OP^*$  is same as OA, the length of  $OP^*$  is same as the length of OA and  $OP^*$  makes  $\theta$  angle with the real axis. So then reflect, then we consider the reflection of point A in the real axis, okay and we get  $P^*$ , okay. So  $OP^*=OA$ , this is  $1/r$ , okay. And argument of  $P^*=-\theta$ , okay. So this means that what we found was we had  $w=1/z$ , so we found that if  $w$  is  $Re^{i\alpha}$  and  $z$  is  $re^{i\theta}$ , then  $1/re^{i\theta}$  we have, this is equal to  $1/r$  to the power  $-i\theta$ .

So  $R=1/r$  and  $\phi=-\theta$ . So we see that  $OP^*=1/r$  and argument of  $P^*=-\theta$  and therefore, the point A under the point P, under the transformation  $w=1/z$  gives us  $P^*$  which  $P^*$  is obtained by considering the inversion of P with respect to the unit circle, we get the point A and then we consider the reflection of the point A in the real axis and we get  $P^*$ . So  $w=1/z$  is regarded as an inversion with respect to the unit circle combined with the reflection in the real axis.

**(Refer Slide Time: 17:23)**

cont...

We saw that a non-constant linear mapping acts by rotating, magnifying and translating points in the complex plane.

As a result, the angle between any two intersecting arcs in the  $z$ -plane is equal to the angle between the images of the arcs in the  $w$ -plane under a linear mapping. Complex mappings that have this angle preserving property, are called conformal mappings.

o

ET ROOFTOP

NPTEL ONLINE  
CERTIFICATION COURSE

5

Now we have seen that non-constant linear mapping, okay, we consider the non-constant linear mapping  $w=az+b$ . It consists of 2 transformations. So you can regard this  $fz=az+b$  as say  $fz=$ , say,  $\zeta a+b$  where  $\zeta a=az$ . So this gives you the mapping of the type  $\beta z$ . This  $w=\beta z$  type, okay. So this is of  $\beta z$  type and this is the mapping of the type  $w=z+\alpha$ . So  $fz=az+b$  consists of 2 transformations, okay.

Translation and this is translation and this one is rotation and magnification. So a non-constant linear mapping acts by rotating, magnifying and translating points in the complex plane. As a result, the angle between any 2 intersecting arcs in the  $z$ -plane is equal to the angle between the images of the arcs in the  $w$ -plane because the linear mapping does not change the shape of the curve, okay. It only rotates or magnifies and translates it.

So the angle between 2 intersecting arcs will remain preserved under a linear mapping. Now the complex mappings that have this angle preserving property are called conformal mappings. So let us discuss conformal mappings in detail.

**(Refer Slide Time: 18:56)**

### Conformal mapping

The most important geometrical property of the analytic functions is their conformality.

Suppose that  $w = f(z)$  is a complex mapping defined in a domain  $D$ . Then the mapping is said to be conformal at a point  $z_0$  in  $D$  if it preserves the angles between oriented curves in magnitude as well as in sense i.e. if  $C_1$  and  $C_2$  are two smooth oriented curves in  $D$  that intersect at  $z_0$

$$z = x(t) + iy(t)$$

Figure : Curves  $C_1$  and  $C_2$  and their respective image  $C_1^*$  and  $C_2^*$  under a conformal mapping.

The most important geometrical property of the analytic functions is their conformality. Suppose that  $w = f(z)$  is a complex mapping defined in a domain  $D$ . Then the mapping is called conformal at a point  $z_0$  in  $D$  if it preserves the angles between oriented curves in magnitude as well as in sense. That is if  $C_1$  and  $C_2$  are 2 smooth oriented curves in  $D$  that intersect. Suppose  $C_1$  is this curve, okay.

This is  $C_1$  and this is  $C_2$ , okay. The angle between the curve  $C_1$  and  $C_2$  is the angle between their respective tangents. So let us say this is the tangent to the curve  $C_1$ . This one is the tangent to the curve  $C_2$ .  $\alpha$  is the angle between them. Now the oriented curves means the; when we write the equation of the curve in the parametric form, suppose it is  $z = z(t) = x(t) + iy(t)$ . Then the curve is said to have a positive sense in the direction in which  $t$  increases, okay.

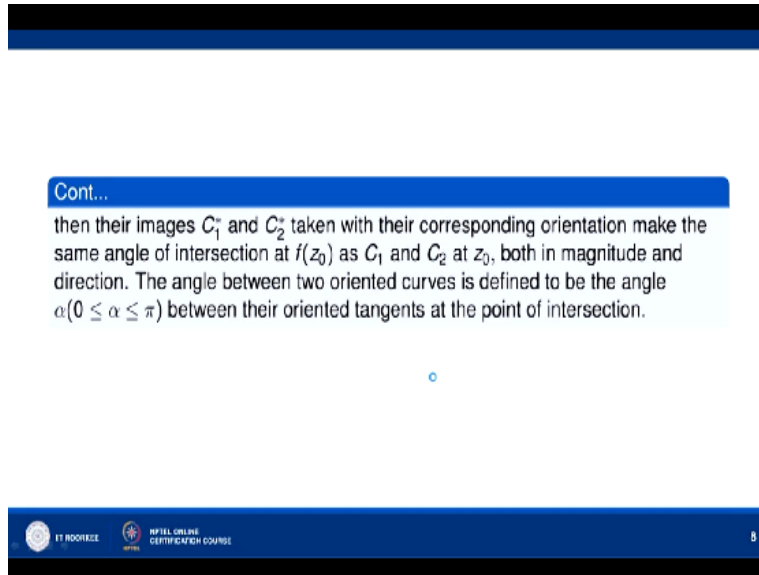

So and the sense along which the curve has a positive sense, the tangent in that same direction will also said to have a positive sense, okay. So these are the tangents, oriented tangents to the curve  $C_1$  and  $C_2$ . And similarly, this  $C_1$  and  $C_2$  under a transformation, under the transformation  $w = f(z)$ , they are mapped into say this curve,  $C_1^*$  and  $C_2^*$ . These oriented tangents to the curve  $C_1^*$  and  $C_2^*$  at their point of intersection, if this point is  $z_0$ , okay, in the  $z$  plane, then this point is  $f(z_0)$  under the transformation  $w = f(z)$ .

So this is  $f(z_0)$  at the point of intersection  $f(z_0)$ , the 2 tangents, oriented tangents to the curves  $C_1^*$

which is the image of  $C_1$  and  $C_2^*$  which is the image of  $C_2$ , okay, make the same angle  $\alpha$  and in the same direction. The direction from  $C_1$  to  $C_2$ . If we are going from  $C_1$  to  $C_2$  here, here also from  $C_1^*$  to  $C_2^*$  when we go, we should be moving in the same direction. So then if the angle is preserved in magnitude as well as in sense, we say that the mapping is conformal.

**(Refer Slide Time: 21:23)**

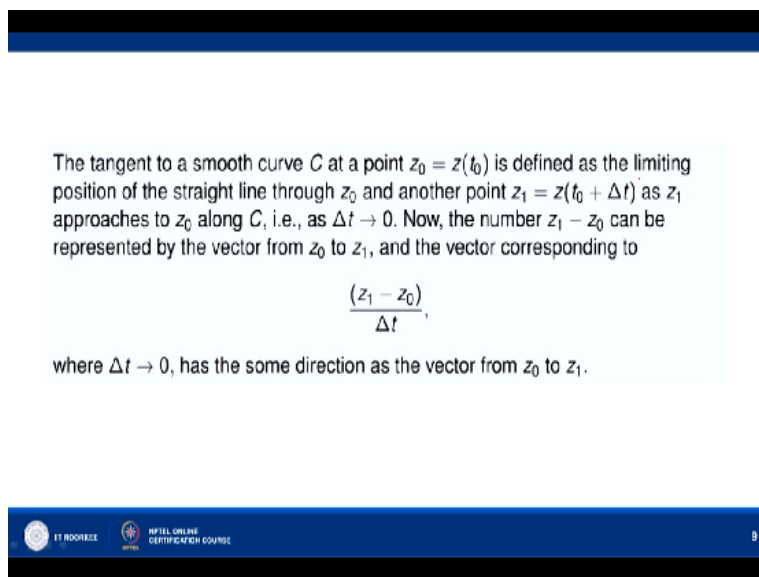

Cont...

then their images  $C_1^*$  and  $C_2^*$  taken with their corresponding orientation make the same angle of intersection at  $f(z_0)$  as  $C_1$  and  $C_2$  at  $z_0$ , both in magnitude and direction. The angle between two oriented curves is defined to be the angle  $\alpha$  ( $0 \leq \alpha \leq \pi$ ) between their oriented tangents at the point of intersection.

9

So the images  $C_1^*$ ,  $C_2^*$  taken with their corresponding orientation should make the same angle and the angle of intersection is the angle between their respective tangents, that angle if it is  $\alpha$ , the  $\alpha$  lies between 0 and  $\pi$ .

**(Refer Slide Time: 21:39)**

The tangent to a smooth curve  $C$  at a point  $z_0 = z(t_0)$  is defined as the limiting position of the straight line through  $z_0$  and another point  $z_1 = z(t_0 + \Delta t)$  as  $z_1$  approaches  $z_0$  along  $C$ , i.e., as  $\Delta t \rightarrow 0$ . Now, the number  $z_1 - z_0$  can be represented by the vector from  $z_0$  to  $z_1$ , and the vector corresponding to

$$\frac{(z_1 - z_0)}{\Delta t},$$

where  $\Delta t \rightarrow 0$ , has the same direction as the vector from  $z_0$  to  $z_1$ .

9

So the tangent to a smooth curve  $C$  at a point  $z_0 = z(t_0)$  is defined as the limiting position of the

straight line through  $z_0$  and another point  $z_1$ ,  $z_1 = z_0 + \Delta t$  as we can see in this figure, okay.

(Refer Slide Time: 21:54)

It follows that the vector corresponding to

$$\dot{z}(t_0) = \left. \frac{dz}{dt} \right|_{t=t_0} = \lim_{\Delta t \rightarrow 0} \frac{z_1 - z_0}{\Delta t} = \lim_{\Delta t \rightarrow 0} \frac{z(t_0 + \Delta t) - z(t_0)}{\Delta t}$$

Figure : Derivation of formula

is tangent to  $C$  at  $t_0$ , and the angle between this vector and the positive  $x$ -axis is  $\arg \dot{z}(t_0)$ .

10

This is any curve  $C$  in the complex plane. The curve  $C$  is defined by  $z = x + iy$ ,  $t$  varies from some  $a$  to  $b$ . When we take  $t = t_0$ , it gives us a point on the curve, okay. Let that be  $z_0$ . So  $z_0 = z(t_0)$ . Now let us take another point on the curve, okay, for the value  $t_0 + \Delta t$ . So  $z_1 = z(t_0 + \Delta t)$  is let us say  $z_1$ , okay. Then we can see that  $z_1 - z_0$ , okay, this is  $z_1$ , this is  $z_0$ , okay. So the number  $z_1 - z_0$  can be represented by the vector from  $z_0$  to  $z_1$ , okay.

This vector can represent the complex number  $z_1 - z_0$ , okay and  $z_1 - z_0 / \Delta t$  will have the same direction as the vector  $z_1 - z_0$ . So as  $\Delta t$  goes to 0, that is as the point  $z_1$  moves along the curve to the point  $z_0$ , okay, then  $z_1 - z_0 / \Delta t$ , okay,  $z_1 - z_0 / \Delta t$  is  $dz/dt$  at  $t = t_0$  which is limit of  $z_1 - z_0 / \Delta t$  as  $\Delta t$  goes to 0 and this is limit  $\Delta t$  goes to 0,  $z(t_0 + \Delta t) - z(t_0) / \Delta t$ . So  $z(t_0)$ , now this, so this limit of this expression  $z(t_0 + \Delta t) - z(t_0) / \Delta t$ , is same as along the tangent, this limit gives us the direction of the tangent to the curve at the point  $t_0$ , that is at the point  $z_0$ .

So  $z(t_0)$  is tangent to the curve  $C$  at the point  $t_0$ . When this point  $z_1$  will move along the curve, as  $\Delta t$  goes to 0,  $z_1$  will move along the curve to the point  $z_0$ . And this vector joining  $z_0$  to  $z_1$ , will move to the tangent to the curve, they will approach to the tangent to the curve at the point  $z_0$ . So this  $z(t_0)$  gives us the direction of the tangent to the curve at  $t_0$ . And the angle between this vector and the positive  $x$  axis, okay, angle between this vector, this vector and the positive  $x$  axis,

okay, this angle, okay, this is the argument of  $z_0$ .

(Refer Slide Time: 24:40)

Now consider the smooth curve  $C_1$  and  $C_2$ , let us consider 2 curves  $C_1$  and  $C_2$ , which are shown in this figure. The curve  $C_1$  and  $C_2$  and their respective  $C_1$  dash and  $C_2$  dash, okay.  $C_1$  dash is the image of this  $C_1$ . And  $C_2$  dash is the image of  $C_2$  under the transformation  $w = \bar{z}$  conjugate, okay. The curve  $C_1$  is given by in the parametric form by  $z_1(t) = t + 2t - t^2 \cdot i$ . And the curve  $C_2$  in the parametric form is given by  $z_2(t) = t + \frac{1}{2} t^2 + 1 \cdot i$ .

$0 \leq t \leq 2$ . Let us find the point of intersection of  $z_1(t)$  and  $z_2(t)$ , okay. So at the point of intersection,  $z_1(t)$  and  $z_2(t)$  will be same. So  $t + 2t - t^2 = t + \frac{1}{2} t^2 + 1$ , okay. So this cancels with this and what we get?  $4t - 2t^2 = t^2 + 1$ . So what we get?  $3t^2 = 3$ , okay. So this means  $t^2 = 1$ , so  $3t^2 - 4t + 1 = 0$ , okay. And when we factorize this, what we get?

We can see that  $t=1$  satisfies this equation.  $3 - 4 + 1$ . So this is  $t-1 \cdot t-1$ , we can multiply by  $3t$ . So  $3t^2 - 2t - 1$ , so we get  $-t+1$ , okay. So  $t-1$  and  $3t-1$ , okay, equal to 0. So  $t=1$  and  $1/3$ . Now  $0 \leq t \leq 2$ , so this is  $z_0$ , this  $z_0$  corresponds to  $t=1$  and this point of intersection corresponds to  $t=1/3$ . We are considering the point of intersection at  $t=1$ .

So when  $t=1$ , what is  $z_1(t)$ ?  $z_1(t)$  will be  $1+i$  and similarly will be  $z_2(t)$  at  $t=1$  and this is  $z_0$ .  $z_0$  is the

point of intersection of  $z_1 t$  and  $z_2 t$  at  $t=1$ , okay. Now so this at the point  $z_1$ , we have this curve. At the point  $z_0$ , this is the curve  $C_1$ , this is the curve  $C_1$ . So argument of  $z_1$ , argument of  $1+i$ . Argument of  $1+i$  we know, it is  $\pi/4$ , okay. Let us find  $z_1 t$ , okay. So  $z_1 t = 1+2-2ti$ , okay. So  $z_1$ , at  $t=t_0$ , that is, so this implies that  $z_1 t_0$ ,  $t_0=1$ , okay.

And when we find  $z_2$ , what we get?  $z_2 = 1+2t/2$ , okay. So  $1+t*i$ , okay, which implies that  $z_2 = 1+i$ , okay. So the angle which the tangent to the vector at  $C_1$ , okay,  $z_1$ , okay, at  $z_1$  dash, okay, it makes with the x axis is 0, okay. This means that argument of  $z_1 = 0$  and argument of  $z_2 = i/4$ , okay. So argument of  $z_1$  gives the angle which the tangent to the curve at  $C_1$  makes with the x axis.

So angle that the curve, tangent to the curve  $C_1$  makes with the x axis is 0 while the tangent to the curve  $C_2$  at the point  $z_0$  makes angle  $\pi/4$ . So this angle  $\pi/4$  is the angle between the tangents to the curve  $C_1$  and  $C_2$  at the point  $z_0$ . Now let us come to the image curves,  $C_1$  dash and  $C_2$  dash.  $C_1$  dash becomes this one, under the mapping  $w=z$  conjugate,  $C$  curve is given by  $C_1$  curve is given by  $z_1 t = t+2t-t^2*i$ .

So image curve will be given  $w_1$  will be given by  $w_1 t = t-2t-t^2*i$  and the image curve  $C_2$  dash will be given by  $w_2 t = t-1/2 t^2+1*i$ , okay. So now let us see  $w_1$ , okay. At the point, where do they intersect  $w_1 t$  and  $w_2 t$ ?  $w_1 t$  and  $w_2 t$  intersect at the point  $fz_0$ , okay. So  $fz_0$ ,  $w=fz=z$  conjugate. So this gives you  $fz_0 = z_0$  bar, okay. And  $fz_0 = z_0 = 1+i$ , okay. So this is  $1+i$  bar, okay.

So  $1-i$ , okay. So they intersect, this is your  $w_0 = 1-i$  point, okay. And if you find  $w_1$ ,  $w_1 = 1-2t-t^2$  means  $2-2t*i$ , okay, in to complex number  $i$ . And  $w_2$  will be what?  $w_2$  will be  $1-1/2*2t=1-t*i$ , okay. And  $t=1$ , okay. So you can see  $t=1$ , so this means that  $w_1 = 1$ ,  $t=1$  means this is 0. So  $w_1 = 1$ .  $w_2 = 1/i$ , okay. So  $w_1$  means the curve  $C_1$  dash, okay. You can see this curve  $C_1$  dash, okay.

It makes angle 0 with the u axis, okay with the real axis.  $w_1$  is parallel to the u axis. So it makes angle 0 and  $w_2 = 1/i$ , okay. It makes angle this one  $\pi/4$  but its argument will be  $-\pi/4$  when you

associate the direction, okay. So  $-\pi/4$ . So here you can see that the angle remains preserved, angle between  $C_1$  and  $C_2$  at the point of intersection  $z_0$  is  $\pi/4$ . At the point  $w_0$  also, the angle between  $C_1$  dash and  $C_2$  dash is  $\pi/4$ .

But here the sense of the angle from  $C_1$  to  $C_2$  is in the anticlockwise direction while here the angle from  $C_1$  dash to  $C_2$  dash is in the clockwise direction, okay, in this direction. So angle is preserved in the magnitude but not in sense and therefore, the mapping  $w=z$  conjugate is not conformal at the point of intersection  $z_0$ , that is at the point  $zw=1+i$ .

**(Refer Slide Time: 33:06)**

**Theorem 1**  
The mapping defined by an analytic function is conformal, except at points where the derivative

$$f'(z) = 0.$$

**Proof**  
Let  $w = f(z) = u(x, y) + iv(x, y)$  be a non constant analytic function defined in a domain containing a smooth oriented curve  $C$ .  
Then the image of  $C$  under this mapping is a curve  $C'$  in the  $w$  plane represented by  $w(t) = f(z(t))$ . The point  $z_0 = z(t_0)$  corresponds to the point  $w(t_0)$  of  $C'$ , and  $w'(t_0)$  represents a tangent vector to  $C'$  this point.

12

So in fact treat the mapping  $w=z$  conjugate is not conformal at any point of the complex plane. Here we have taken 2 particular curves and showed that it is not conformal at their point of intersection but it is not-conformal at any point of the  $z$  plane. Now let us consider the theorem which says that the mapping defined by an analytic function is conformal, at all points except at those points where the derivative is 0.

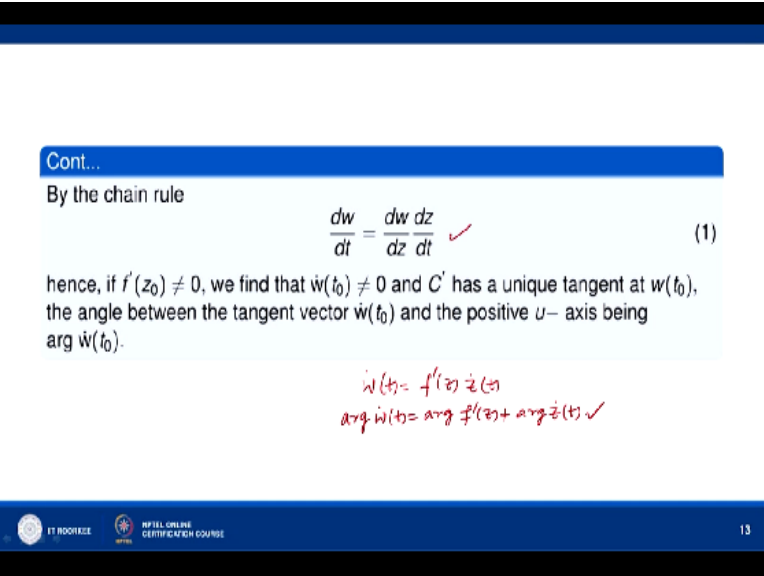

So this is very important theorem because from this theorem, we can easily test the points where while giving mapping is a conformal mapping by finding its derivative. So the points where the derivative vanishes are called the critical points of the mapping. The points where the derivative does not exist of a complex function, those points are also called the critical points. So critical points actually consist of those points where the derivative, either the derivative of the function

$w=fz$  does not exist or it is 0.

So here let us consider the analytic function. An analytic function is differentiable infinitely, so we can say that it is conformal at all points except at the critical points, that is the points where its derivative is 0. So let us say, let us prove this. Let  $w=fz=uxy+ivxy$  be a non-constant analytic function defined in a domain containing a smooth oriented curve  $C$ . Then the image of  $C$  under this mapping is a curve  $C'$  in the  $w$  plane represented by  $w=fz$ .

The point  $z_0=z(t_0)$  corresponds to the point  $w(t_0)$  of  $C'$  and  $w'(t_0)$  as we have already discussed represents the tangent to the curve  $C'$  at the point  $t=t_0$ .

(Refer Slide Time: 35:01)

Cont...

By the chain rule

$$\frac{dw}{dt} = \frac{dw}{dz} \frac{dz}{dt} \quad (1)$$

hence, if  $f'(z_0) \neq 0$ , we find that  $w'(t_0) \neq 0$  and  $C'$  has a unique tangent at  $w(t_0)$ , the angle between the tangent vector  $w'(t_0)$  and the positive  $u$ -axis being  $\arg w'(t_0)$ .

*Handwritten notes:*

$$w(t) = f(z) \dot{z}(t)$$

$$\arg w(t) = \arg f(z) + \arg \dot{z}(t) \quad \checkmark$$

FT ROOPEE NPTEL ONLINE CERTIFICATION COURSE 13

Now by the chain rule,  $dw/dt = dw/dz * dz/dt$ , okay. So if  $f'(z_0)$  is not equal to 0, then from here you can see  $w'(t_0)$  is not equal to 0, okay. And therefore,  $C'$  has a unique tangent at the point  $w(t_0)$ . Now the angle between the tangent vector  $w'(t_0)$  and the positive  $u$  axis is given by argument of  $w'(t_0)$ .

(Refer Slide Time: 35:32)

Cont...

From (1)  $\dot{w}(t_0) = \arg f'(z_0) + \arg \dot{z}(t_0)$ . Thus, under the mapping, the tangent to  $C$  at  $z_0$  is rotated through the angle  $\arg \dot{w}(t_0) - \arg \dot{z}(t_0) = \arg f'(z_0)$ , the angle between those two tangent vectors to  $C$  and  $C'$ .

Since the expression on the right is independent of the choice of  $C$ , we see that this angle is independent of  $C$  i.e. the transformation  $w = f(z)$  rotates the tangents of all the curves through  $z_0$  through the same angle  $\arg f'(z_0)$ . Hence, two curves through  $z_0$  which form a certain angle at  $z_0$  are mapped upon curves forming the same angle, in sense as well as in magnitude, at the image point  $w_0$  of  $z_0$ .

NPTEL ONLINE  
CERTIFICATION COURSE

14

From this equation, we find that argument of  $w_0 \dot{t}_0 = \arg w_0 + \arg \dot{t}_0$ . This is  $w_0 \dot{t}_0 = f'(z_0) \dot{z}_0$ , okay. So we know that argument of  $z_1 z_2$  is argument of  $z_1$  + argument of  $z_2$ . So argument of  $w_0 \dot{t}_0 = \arg f'(z_0) + \arg \dot{z}_0$ . So from here, it follows that argument of  $w_0 \dot{t}_0 = \arg f'(z_0) + \arg \dot{z}_0$ . Now under the mapping, the tangent to  $C$  at the point  $z_0$  is rotated through the angle, okay.

We can see. It is rotated through the angle. Argument of  $w_0 \dot{t}_0 - \arg \dot{z}_0$ , okay. So suppose you have this curve, let us say, in the  $z$  plane. Let us say this curve we have curve  $C$ , okay. So this curve will be rotated by argument of  $f'(z_0)$ , okay, in the  $w$  plane, okay. So the tangent to the curve, let us say you take this tangent to the curve at the point  $z_0$ , okay. Then this is your  $w_0 \dot{t}_0$  suppose.

The tangent to the curve at the point  $w_0$  will be rotated by angle given by argument of  $f'(z_0)$ . Argument of  $w_0 \dot{t}_0 - \arg \dot{z}_0$ , this gives the angle by which the tangent to the curve  $C$  at the point  $z_0$  is rotated, okay. So that is given by argument of  $f'(z_0)$ , the angle between those 2 tangent vectors to  $C$  and  $C'$ , okay. So since the expression on the right, now this expression is independent of the choice of  $C$ .

This angle is independent of  $C$ . The transformation  $w = f(z)$  therefore rotates the tangents of all curves through  $z_0$  through the same angle argument of  $f'(z_0)$ . Hence, 2 curves through  $z_0$ , if

you take 2 curves through  $z_0$ . Let us say we have 2 curves through  $z_0$ ,  $C_1$  and  $C_2$ , okay. This is  $C_1$  and this is  $C_2$ , okay.

So this is the tangent to the curve  $C_1$  and this is the tangent to the curve  $C_2$ , okay. If this angle is say  $\alpha$ , okay, then both these curves, okay, are rotated by the same angle, okay given by argument of  $f'(z_0)$ . So this is  $C_1$  dash and this is  $C_2$  dash for example, okay. Then this is the tangent to the curve  $C_1$  dash. Then this is the tangent to the curve  $C_2$  dash.

The angle between the 2 curves will remain  $\alpha$  because  $C_1$  is rotated by argument of  $f'(z_0)$  and  $C_2$  is also rotated by argument of  $f'(z_0)$ , so the angle between  $C_1$  and  $C_2$  does not change, okay. So hence 2 curves through  $z_0$  which form a certain angle at  $z_0$  are mapped upon curves forming the same angle in sense as well as in magnitude at the image point  $w_0$  of  $z_0$ .

(Refer Slide Time: 39:19)

**Example 2**  
Consider the mapping  $w = z^2 = f(z)$ .  
Handwritten notes:  $\frac{dw}{dz} = f'(z) = 2z$ ,  $f'(z) \neq 0$  at  $z \neq 0$ .  
Diagram: A complex plane with a point  $z$  in the first quadrant. Two rays from the origin, one at angle  $\theta$  and another at angle  $2\theta$ , are shown. The angle between them is  $\theta$ , illustrating that the mapping is not conformal at the origin.

**Example 3**  
Consider the entire function  $f(z) = e^z$ .  
Handwritten notes:  $f'(z) = e^z \neq 0$  for any  $z \in \mathbb{C}$ .  
 $\Rightarrow f(z) = e^z$  is conformal  $\forall z \in \mathbb{C}$ .  
Diagram: A complex plane with a point  $z = re^{i\theta}$ . Two rays from the origin, one at angle  $\theta$  and another at angle  $\theta + \phi$ , are shown. The angle between them is  $\phi$ , illustrating that the mapping is conformal everywhere.

Now let us consider the mapping  $w=z$  square. So we can see that  $dw/dz$  or you can say  $f'(z)$  if I take it  $fz$ , then this is equal to  $2z$ , okay. So  $f'(z) \neq 0$  at  $z \neq 0$ . This means that  $w=z$  square is not conformal, okay at  $z=0$ . At any other point, any point other than the origin, it is a conformal mapping. Now let us see how it is not conformal at  $z=0$ . It will be easy to take say  $OP$  which makes angle  $\pi/4$ , okay and this  $y$  axis, okay  $OQ$  which makes angle  $\pi/2$ , okay.

So let us take these 2 arcs, these 2 rays, let us take these 2 rays. Then  $OP$ ,  $2=z$  square, so  $Rei$

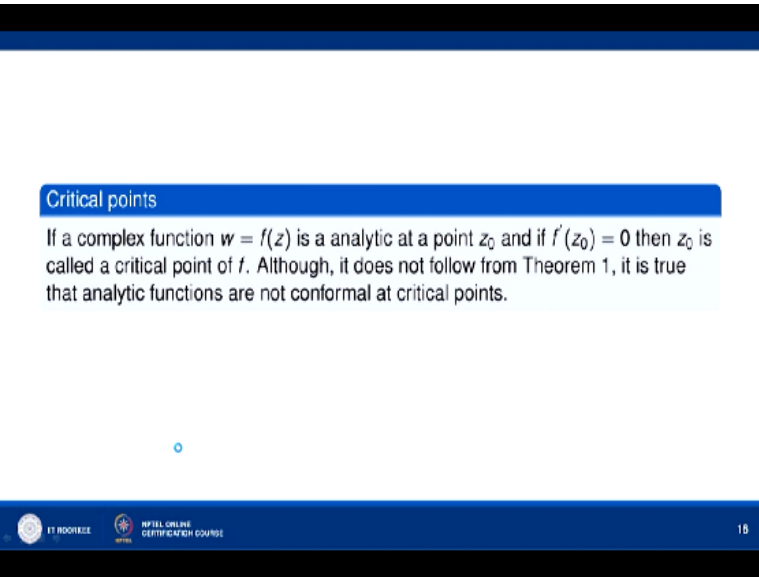

$\phi = r^2 e^{2i\theta}$ , if  $z = re^{i\theta}$  and  $w = Re^{i\phi}$ . So  $R = r^2$  and  $\phi = 2\theta$ , okay. Now this is  $\theta = \pi/4$ , okay. So  $\theta = \pi/4$  will become  $\pi/2$ , okay. So this is  $z$  plane, okay. So  $OP$  will be mapped on to  $OP'$  here, okay.  $OP$  will go to  $OP'$  and  $OQ$ , this makes angle  $\pi/2$ , okay.

So this will be mapped on to negative  $u$  axis, okay. This is  $OQ'$ , okay. And we can see that angle between  $OP$  and  $OQ$  is  $\pi/4$ , okay. Here the angle between  $OP'$  and  $OQ'$  becomes  $\pi/2$ , okay. Because  $\phi = 2\theta$ , so  $OP$  makes angle  $\pi/4$  will go to  $OP'$  which makes angle  $\pi/2$  and  $OQ$  makes angle  $\pi/2$  with the  $x$  axis, so  $OQ'$  will make an angle  $\pi$  with the  $u$  axis, okay. And therefore, the angle between  $OP'$  and  $OQ'$  is  $\pi/2$ .

So angles are doubled at the origin. And therefore, the angle between 2 curves, okay, here they are rays, okay,  $OP$  and  $OQ$ . The angle between 2 rays is not preserved at the origin and so  $w = z^2$  is not conformal at the origin. Now if you consider the other example,  $fz = e^z$ , we know that it is an entire function because it is differentiable for all finite complex numbers  $z$ . So and if you find  $f'(z) = e^z$ .

And we know that  $e^z$  is not equal to 0 for any complex number  $z$ . And therefore,  $fz = e^z$  is conformal for all  $z$  belonging to  $\mathbb{C}$ .

**(Refer Slide Time: 43:14)**

**Critical points**

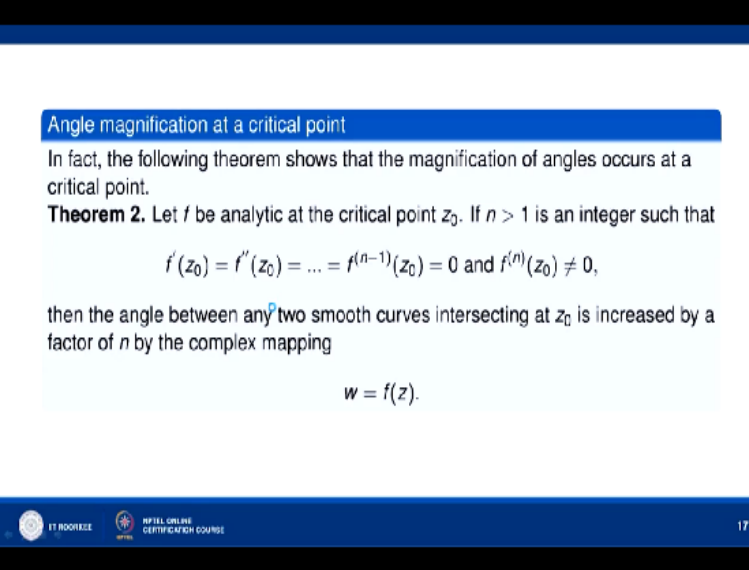

If a complex function  $w = f(z)$  is analytic at a point  $z_0$  and if  $f'(z_0) = 0$  then  $z_0$  is called a critical point of  $f$ . Although, it does not follow from Theorem 1, it is true that analytic functions are not conformal at critical points.

ET ROOFTREE NPTEL ONLINE CERTIFICATION COURSE 18

Now let us consider critical points as I had already said if a complex function  $w=fz$  is analytic at a point  $z_0$  and if the derivative at  $z_0$  vanishes, then  $z_0$  is called a critical point of  $f$ . Now it does not follow from theorem 1 that analytic functions which are not conformal, it does not follow that, if  $f'(z_0)=0$ , then the analytic function cannot be; see from this theorem, it follows that if you look at this theorem, okay.

It says that the mapping is conformal at every point  $z$  where  $f'(z)$  is not equal to 0. Now if  $f'(z)=0$ , then why the mapping is not conformal? Why it cannot be conformal? See it does not follow from theorem 1 that analytic functions are not conformal at critical points. The point where  $f'(z)=0$ . It only says that wherever derivative is not 0, the mapping is conformal. But why it is not conformal at the points where  $f'(z)=0$ , it follows from the second theorem.

**(Refer Slide Time: 44:26)**

**Angle magnification at a critical point**

In fact, the following theorem shows that the magnification of angles occurs at a critical point.

**Theorem 2.** Let  $f$  be analytic at the critical point  $z_0$ . If  $n > 1$  is an integer such that

$$f'(z_0) = f''(z_0) = \dots = f^{(n-1)}(z_0) = 0 \text{ and } f^{(n)}(z_0) \neq 0,$$

then the angle between any two smooth curves intersecting at  $z_0$  is increased by a factor of  $n$  by the complex mapping

$$w = f(z).$$

ET ROOPEEE NPTEL ONLINE CERTIFICATION COURSE 17

This theorem tells us that the magnification of angles occurs at a critical point, okay. So angles are not preserved actually at a critical point and therefore, wherever the function, analytic function has derivative 0, it cannot be conformal at those points. So let  $f$  be analytic at the critical point  $z_0$ . Suppose  $n > 1$  is an integer such that  $f'(z_0) = 0$ ,  $f''(z_0) = 0$  and one of the derivative of  $fz$  at  $z_0$  is 0 but the  $n$ th derivative is non-0, then the angle between any 2 smooth curves intersecting at  $z_0$  is increased by a factor of  $n$  by the complex mapping.

So if you have angle between any 2 intersecting curves at the point  $z_0$ , then at the point  $w_0$

in the  $w$  plane, the angle between the corresponding images will be  $n \cdot \alpha$ . So the angle is not preserved and therefore, we can say that at the critical point, the analytic function  $fz$  does not have, is not conformal. So let us prove this result by our hypothesis.

(Refer Slide Time: 45:31)

**Proof**

By our hypothesis, we have

$$f(z) - f(z_0) = (z - z_0)^n \left[ \frac{f^{(n)}(z_0)}{n!} + (z - z_0) \frac{f^{(n+1)}(z_0)}{(n+1)!} + \dots \right] = (z - z_0)^n g(z)$$

where  $g$  is analytic at  $z_0$  and  $g(z_0) \neq 0$ . Thus,

$$\begin{aligned} \arg(w - w_0) &= \arg(f(z) - f(z_0)) \\ &= n \arg(z - z_0) + \arg g(z). \end{aligned}$$

$g(z_0) = \frac{f^{(n)}(z_0)}{n!}$   
 $z = r e^{i\theta}$   
 $z^n = r^n e^{i n \theta}$

18

We have assumed that  $fz$  is analytic at the point  $z_0$ . So we can, by our hypothesis, we can write its Taylor series expansion  $fz = fz_0 + f'z_0 \cdot z - z_0$  and so on. And then because  $f'z_0, f''z_0, \dots, f^{(n-1)}z_0$  are all 0 but the  $n$ th derivative is non-0, the power series reduces to this, okay.  $fz = fz_0 + (z - z_0)^n \frac{f^{(n)}z_0}{n!} + \dots$  to the power  $n+1$   $f^{(n+1)}z_0 / (n+1)!$  and so on.

And this I can write in this form.  $z - z_0$  to the power  $n$  we can take as a common factor and then the remaining expression inside the bracket will represent an analytic function  $g(z)$  and this  $g(z)$  analytic function at  $z_0$  is not equal to 0 because  $g(z_0) = f^{(n)}z_0 / n!$ .  $f^{(n)}z_0$  is not equal to 0. So  $g(z_0)$  is not equal to 0. And therefore, argument of  $w - w_0$ ,  $w = fz$ ,  $w_0$  is  $fz_0$ . So argument of  $fz - fz_0 = n \cdot \arg(z - z_0) + \arg g(z)$ , okay, + argument of  $g(z)$ .

Argument of  $z$ , we know that if  $z = r e^{i\theta}$ , so  $\theta$  is the argument of  $z$ , then  $z$  to the power  $n$  is  $r^n e^{i n \theta}$ . So argument of  $z$  to the power  $n$  becomes  $n \cdot \arg(z)$ . So here argument of  $z - z_0$  to the power  $n$  is  $n \cdot \arg(z - z_0) + \arg g(z)$ , okay.

(Refer Slide Time: 47:25)

Cont...

Let  $\alpha$  be the angle which the tangent vector to a smooth curve  $\gamma$  at  $z_0$  makes with the positive  $x$  axis, and  $\beta$  be the angle which tangent to the image curve  $\Gamma$  under  $w = f(z)$  at  $w_0 = f(z_0)$  makes with the positive  $u$ -axis.

If  $z \rightarrow z_0$  along  $\gamma$ , then

$$w = f(z) \rightarrow w_0 = f(z_0)$$

along  $\Gamma$  so that the last equation gives

$$\beta = n\alpha + \arg(a_n) \text{ where } a_n = \frac{f^{(n)}(z_0)}{n!}$$

Now let alpha be the angle which the tangent vector to a smooth curve gamma at  $z_0$  makes with the positive  $x$  axis, let us take this, okay. Suppose we have this curve, okay, a smooth curve, okay, and suppose this is your point  $z_0$ , the curve, the tangent at the point  $z_0$ , okay, makes an angle; this is your curve, a smooth curve we have denoted by gamma. So this smooth curve by gamma and here this angle is alpha, okay.

This angle which the tangent to the curve at the point  $z_0$  makes with the positive  $x$  axis. Beta be the angle with the tangent to the image curve gamma, okay. Let us take this  $w$  plane. So in the  $w$  plane, suppose this is the curve, okay, capital gamma and this is your point  $w_0 = f(z_0)$ , okay. So tangent to this curve at this point makes this angle. This angle is beta let us say, okay. Beta be the angle which is the tangent to the image curve gamma at  $w = f(z)$ , okay and the  $w = f(z)$  at  $w_0$  makes with the positive  $u$  axis.

Then if  $z$  tends to  $z_0$  along gamma. If  $z$  tends to  $z_0$ , let us say  $z$  be any point here. If  $z$  tends to  $z_0$  along gamma, then  $w$  tends to  $w_0$ , okay. This is  $w$ , okay, tends to  $w_0 = f(z_0)$  along gamma. So that the last equation gives; from the last equation, what do we notice? As  $z$  tends to  $z_0$ , this equation will give you this one, okay.  $\beta = \arg(n\alpha + a_n)$ , okay. This is  $fz$ -, argument of  $fz - fz_0$ .  $fz - fz_0$  is this vector, okay, this vector, okay. You can join  $w - w_0$  and this is  $z - z_0$ .

So as  $z$  tends to  $z_0$ , you will get the direction of the tangent here. And when  $z$  tends to  $z_0$ ,  $w$  will tend to  $w_0$ . So it will give you the direction of the tangent here. So this when  $z$  tends to  $z_0$ , argument of  $w-w_0$  tends to  $\beta$  and argument of  $z-z_0$  tends to  $\alpha$ , okay. And this becomes argument of  $gz_0$ . So what we have?  $\beta$  will be equal  $n\alpha + \text{argument of } gz_0$ .  $gz_0$  is an  $n$ th order zero of  $f(z)$ .

(Refer Slide Time: 50:08)

Cont...

Let  $\gamma_1$  and  $\gamma_2$  be two smooth curves passing through  $z_0$  and let  $\Gamma_1$  and  $\Gamma_2$  be their respective images under  $w = f(z)$ . Suppose that the tangents to the curves  $\gamma_k$  and  $\Gamma_k$  make an angle  $\alpha_k$  and  $\beta_k$  with the real axis of the  $z$ -plane and of the  $w$ -plane, respectively for  $k = 1$  and  $2$ .

$\alpha = \alpha_1 - \alpha_2$        $\beta = \beta_1 - \beta_2$

ET ROORKEE      NITEL ONLINE CERTIFICATION COURSE

20

Now let  $\gamma_1$  and  $\gamma_2$  be 2 smooth curves passing through  $z_0$ . Take 2 curves. Suppose this is  $\gamma_1$  curve and this is another curve, okay. This is  $\gamma_1$ , this is  $\gamma_2$ , okay in the  $z$ -plane. And let  $\Gamma_1$  and  $\Gamma_2$  be 2 smooth curves passing through  $w_0$ , okay. And let  $\Gamma_1$ ,  $\Gamma_2$  will be corresponding images. This is  $\Gamma_1$  and this is  $\Gamma_2$ , okay.

This is  $z_0$ , so this is  $f(z_0)$  or  $w_0$ , okay.  $\gamma_1$  and  $\gamma_2$  with their respective images and the  $w=f(z)$ , suppose that the tangents to the curves  $\gamma_k$  and  $\Gamma_k$  make an angle  $\alpha_k$  and  $\beta_k$  with the real axis of the  $z$ -plane. So let us say  $\gamma_1$  makes angle  $\alpha_1$ , okay.  $\gamma_2$  makes angle at the point of intersection  $\alpha_2$ , okay. Here  $\gamma_1$ ,  $\Gamma_1$  makes angle  $\beta_1$ .

This  $\Gamma_2$  makes angle  $\beta_2$ , okay. Then so  $\gamma_k$  and  $\Gamma_k$  makes angle  $\alpha_k$  and  $\beta_k$  with real axis of the  $z$ -plane and  $w$ -plane respectively for  $k=1$  and  $2$ , okay.

(Refer Slide Time: 51:54)

Cont...

Then we have

$$\beta_1 = n\alpha_1 + \arg(a_n)$$

and

$$\beta_2 = n\alpha_2 + \arg(a_n)$$

$\Rightarrow \beta = n\alpha$ , where  $\alpha = \alpha_1 - \alpha_2$  and  $\beta = \beta_1 - \beta_2$  ✓

are respectively the angles between the curves  $\gamma_1, \gamma_2$  and the respective image curves  $\Gamma_1, \Gamma_2$ .

From Theorem 2, it follows that no analytic function can be conformal at its critical points.

ET ROOFTOP MPTEL ONLINE CERTIFICATION COURSE 21

Then beta 1 will be equal to n alpha 1+argument of an. Beta 2 will be n alpha 2+argument of an. And this will imply that alpha, if you take alpha=alpha 1-alpha 2, so alpha=alpha 1-alpha 2. And beta=beta 1-beta 2, okay. So then what happens? If we take alpha=alpha 1-alpha 2, beta=beta 1-beta 2 respectively. Then the angle between gamma 1, gamma 2, okay and their images, capital gamma 1, capital gamma 2, okay, will be like this.

So beta 1-beta 2 will be beta=n\*alpha 1-alpha 2, that is alpha. So you will have argument of an will cancel. So beta=n alpha, okay. So you can see the angle between the 2 curves, this angle, okay, beta, this angle is alpha and this angle is beta, okay. Beta becomes n alpha. So from this theorem, it follows that; so the angle at the point of intersection is not preserved at a critical point. So from this theorem, it follows that no analytic function can be conformal at its critical points. The angle gets magnified. It becomes n\*the angle between the curves in the z plane.

(Refer Slide Time: 53:28)

#### Example 4

Find all points where the mapping

$w = \sin z \rightarrow$  entire function  
 is conformal.  
 $f'(z) = \frac{dw}{dz} = \cos z = 0 \Rightarrow z = (2n+1)\frac{\pi}{2}, n=0, \pm 1, \pm 2, \dots$   
 $\Rightarrow f(z)$  is not conformal at  $z = (2n+1)\frac{\pi}{2}, n=0, \pm 1, \pm 2, \dots$   
 $z = (2n+1)\frac{\pi}{2}, n=0, \pm 1, \pm 2, \dots$  are critical points of  $\sin z$   
 $f''(z) = -\sin z$   
 $f''(z) \neq 0$  at  $z = (2n+1)\frac{\pi}{2}, n=0, \pm 1, \pm 2, \dots$   
 Actually  $f''(z) = \pm 1$  at  $z = (2n+1)\frac{\pi}{2}, n=0, \pm 1, \pm 2, \dots$   
 Here  $n=2$

Now let us consider the mapping  $w = \sin z$ , okay. So we see that it is an entire function. And if you find its derivative, then  $dw/dz = \cos z$ , okay. And  $\cos z = 0$  gives  $z = 2n+1 \cdot \pi/2$  where  $n=0, +1, +2$  and so on, okay. And this  $f'$  prime  $z$ . So  $f'$  prime  $z$  is 0 at  $z = 2n+1 \cdot \pi/2$  where  $n=0, +1, +2$  and so on. So this means that  $fz$  is not conformal at  $z = 2n+1 \cdot \pi/2$ ,  $n=0, +1, +2$  and so on. At all other points, it is conformal, okay.

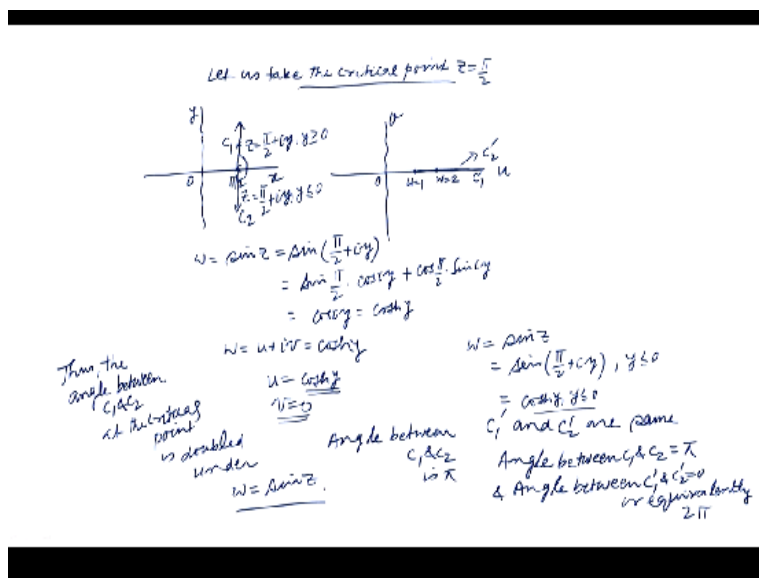

Now if you find second derivative  $f''$  double prime  $z$ .  $f''$  double prime  $z$  is  $-\sin z$ , okay. So  $f''$  double prime  $z$  is not equal to 0 at  $z = 2n+1 \cdot \pi/2$ , okay,  $n=0, +1, +2$  and so on. Actually  $f''$  double prime  $z = \pm 1$  at  $z = 2n+1 \cdot \pi/2$ . So the theorem 2 tells us that at these critical points, these are critical points,  $z =$ ; because the derivative of  $fz$  vanishes at  $z = 2n+1 \cdot \pi/2$ . So  $z = 2n+1 \cdot \pi/2$  are the critical points of  $\sin z$ .

And since  $f''$  double prime  $z$  is not equal to 0, the theorem 2 tells us that at the critical points  $z = 2n+1 \cdot \pi/2$ , the angle between any 2 intersecting curves in the  $z$  plane if it is  $\alpha$ , it will be doubled in  $w$  plane. Because the theorem 2 tells us that the angle between any 2 intersecting curves at the point critical point in the  $z$  plane is multiplied by  $n$ , okay, where  $n$  is the number which is greater than,  $n$  is the positive integer greater than 1 such that  $f'$  prime  $z_0$  equal to 0,  $f''$  double prime  $z_0$  equal to 0,  $n-1$ th derivative of  $fz_0$  is 0 but  $n$ th derivative is non-0.

And here we notice that  $f''$  double prime  $z_0$  is not equal to 0. So  $n=2$  here, okay. So here  $n=2$ . So

let us now show that the angle at critical points between 2 intersecting curves doubles here.

(Refer Slide Time: 57:13)

Now let us show that, let us take the critical point  $z = \pi/2$ . We see that critical points are,  $z$  is given by  $z = 2n+1 \cdot \pi/2$  where  $n$  can take value 0,  $-1$ ,  $-2$  and so on. So let us take  $n=0$ . So let us consider the critical point  $z = \pi/2$ , okay. Let us consider the  $z$  plane. Here this is, so let us consider the point  $\pi/2$  here, okay. Let us consider the ray, this ray, okay. Any point  $z$  on this ray will have equation  $z = \pi/2 + iy$ , okay.

So let us consider the ray  $C_1$  emanating from  $z = \pi/2$  and then let us see under the mapping  $w = \sin z$ , what happens to the image of  $C_1$ , okay? So  $w = \sin z$  gives  $\sin$  of  $\pi/2 + iy$ , okay. So this is  $\sin \pi/2 \cdot \cos iy + \cos \pi/2 \cdot \sin iy$ .  $\sin \pi/2$  is 1,  $\cos \pi/2$  is 0. So we have  $\cos iy$ . And  $\cos iy = \cosh y$ , okay. So  $w$  is equal to  $u + iv = \cosh y$ . So this means that  $u$  is  $\cosh y$  and  $v = 0$ , okay.

So this means that the ray  $C_1$  is mapped on to the real axis. This point  $\pi/2$  goes to; when your  $z = \pi/2$ , okay, this goes to  $w = 1$ , okay. So this is  $w = 1$  here and here you have  $w = 2$  and so on, okay. So this  $\cosh y$ , okay, and  $w = \cosh y$  gives you  $u = \cosh y$ ,  $v = 0$ , so this is mapped into this ray,  $C_1'$  dash, okay. This ray given by this  $w = \pi/2 + iy$  where  $y$  is greater than or equal to 0, okay, is mapped to the ray emanating from  $w = 1$  along the  $u$  axis, okay.

Because  $v=0$ , okay. Only  $u$  is there,  $u$  is  $\cosh y$ , okay. And  $y$  is greater than or equal to 0. So when  $y=0$ , we get here  $\pi/2$ . That  $\pi/2$  maps into  $\cos$ ; this  $y=0$  means this  $\pi/2$  point.  $\pi/2$  here, it goes to 1. So this  $w=1$  is the image of  $z=\pi/2$ , okay. Now let us take another ray  $C_2$ , okay. So  $C_2$  now will have equation, it is emanating from  $\pi/2$  and going in the  $y$  direction just opposite of  $C_1$ , okay.

So this is  $z=\pi/2-iy$ , okay. Or you can say  $\pi/2+iy$ ,  $y$  less than or equal to 0, okay. So  $z=\pi/2+iy$  where  $y$  is less than or equal to 0. So this  $C_2$  will map into  $C_2$  dash and  $w=\sin z$  will again give the same value,  $\sin \pi/2+iy$  where  $y$  is less than or equal to 0. This is  $\cosh y$  where  $y$  is less than or equal to 0, okay. But  $\cosh y$  always assumes positive values, okay. It is an even function of  $y$ .

So whatever values it takes for  $y$  greater than or equal to 0, same values it takes for  $y$  less than or equal to 0. And therefore, what happens?  $C_2$  is also mapped into the same image,  $C_2$  dash and  $C_1$  dash are same, okay. Now angle between  $C_1$  and  $C_2$  is  $\pi$ , okay at the critical point  $\pi/2$ . But here this point, the critical point  $z_0$  is mapped into  $w=1$ . And the angle between  $C_1$  dash and  $C_2$  dash is 0 which is same as  $2\pi$ , okay.

So angle between  $C_1$  dash and  $C_2$  dash is  $2\pi$ . So the angle between  $C_1$  and  $C_2$  which is  $\pi$  is doubled here. It becomes  $2\pi$ , okay. So angle between  $C_1$  and  $C_2$  is equal to  $\pi$  and angle between  $C_1$  dash and  $C_2$  dash is 0 are equivalently  $2\pi$ . Thus the angle between  $C_1$  and  $C_2$  at the critical point  $\pi/2$  is doubled under  $w=\sin z$ . So this verifies the theorem 2. With that, I would like to end this lecture. Thank you very much for your attention.
