Conformal Mappings from Half Plane to Disk and Half Plane to Half Plane - I

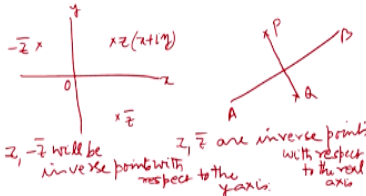

Hello friends. Welcome to my lecture on conformal mappings from half plane to disk and half plane to half plane. So there will be 2 lectures on this topic. This is first of those 2 lectures. Let us first define inverse points with respect to a line. Two points P and Q are said to be inverse points with respect to a line say AB if Q is the image of P in AB . That is if the line AB is the right bisector of PQ .

So if you take a line let us say AB , then two points P and Q are said to be inverse points with respect to the line AB if AB is the right bisector of PQ okay.

(Refer Slide Time: 01:06)

Inverse points with respect to a line

The two points P and Q are said to be the inverse points with respect to the line AB if Q is the image of P in AB i.e. if the line AB is the right bisector of PQ .

z, \bar{z} will be inverse points with respect to the x -axis.

z, \bar{z} are inverse points with respect to the y -axis.

2

For example, if you take in the z -plane if you take the real axis okay x -axis the real axis, then you take any complex number z , the inverse point of the complex number z with respect to real axis will be z conjugate okay. So with respect to the real axis, the z and z conjugate will be inverse points and with respect to y -axis we shall have if z is $z+iy$ then we will have $-z$ conjugate okay.

So that will be the inverse points okay for z with respect to y -axis. So with respect to x -axis, z and z conjugate are inverse points with respect to x -axis that is the real axis in the z -plane, z

and $-z$ conjugate will be inverse points in the z -plane with respect to the imaginary axis the y -axis okay. Now let us see how we define the inverse points with respect to a circle.

(Refer Slide Time: 02:48)

Inverse points with respect to a circle

Two points P and Q are said to be the inverse points with respect to a circle Γ if they are collinear with the center C and on the same side of it, and if the product of their distances from the center is equal to r^2 where r is the radius of the circle. From the above definition, it follows that every point other than the center of the circle possesses a unique inverse. The center of the circle and the point at infinity are inverse points for the circle. This is also consistent with the condition

$$pz_1\bar{z}_2 + \alpha\bar{z}_2 + \bar{\alpha}z_1 + r = 0 \quad (1)$$

$CP \cdot CQ = r^2$

IIT ROORKEE

NPTEL ONLINE CERTIFICATION COURSE
3

Two points P and Q are said to be the inverse points with respect to a circle Γ if they are collinear with the center. So let us take any circle okay. So let us say C is the center, circle is Γ , then two points P and Q are called inverse points with respect to the circle Γ if they are collinear with the center okay, if they are collinear with the center C and on the same side of it okay.

And if the product of their distances from the center is equal to r square, that means $CP \cdot CQ$ is r square where r is the radius of the circle. So from the above definition, it follows that every point other than the center of the circle, you take any point other than the center of the circle it possesses a unique inverse okay. The center of the circle and the point at infinity are inverse points for the circle.

Now this center of the circle and the point at infinity are inverse points for the circle. This is also consistent with the condition $pz_1\bar{z}_2 + \alpha\bar{z}_2 + \bar{\alpha}z_1 + r = 0$.

(Refer Slide Time: 04:17)

for two points z_1, z_2 to be inverse points for the circle

$$pz\bar{z} + \alpha\bar{z} + \bar{\alpha}z + r = 0 \quad (p, r \in \mathbb{R}) \quad (2)$$

From (1), we have

$$\bar{z}_2 = -\left(\frac{r + \bar{\alpha}z_1}{\alpha + pz_1}\right)$$

Since the centre of the circle (2) is $-\frac{\alpha}{p}$, taking $z_1 = -\frac{\alpha}{p}$ in (3), we see that \bar{z}_2 and, therefore, also z_2 is equal to ∞ .

Handwritten notes:
 circle with centre $(-\frac{\alpha}{p})$
 radius $= \sqrt{\frac{|\alpha|^2 - r}{p^2}}$
 $(z + \frac{\alpha}{p})(\bar{z} + \frac{\bar{\alpha}}{p}) = \frac{|\alpha|^2 - r}{p^2}$
 $|z + \frac{\alpha}{p}| = \sqrt{\frac{|\alpha|^2 - r}{p^2}}$

IT ROORKEE
 NPTEL ONLINE
 CERTIFICATION COURSE

For two points z_1, z_2 to be inverse points for the circle $pz\bar{z} + \alpha\bar{z} + \bar{\alpha}z + r = 0$ where p and r are real numbers. This is the equation of any circle or straight line in the z -plane. If p is not equal to 0, it represents a circle. If $p = 0$, then it represents a straight line in the z -plane. So you can also see that $pz\bar{z} + \alpha\bar{z} + \bar{\alpha}z + r = 0$ we can write as if you divide this because p is not equal to 0 we can divide this equation by p .

So then we get $z\bar{z} + \frac{\alpha}{p}\bar{z} + \frac{\bar{\alpha}}{p}z + \frac{r}{p} = 0$. So that we can write it as $z + \frac{\alpha}{p} = -\frac{\bar{\alpha}\bar{z} + \frac{r}{p}}{z}$ okay. So this gives you $z + \frac{\alpha}{p} = -\frac{\bar{\alpha}\bar{z} + \frac{r}{p}}{z}$ okay. So I can write it as $|z + \frac{\alpha}{p}| = \sqrt{\frac{|\alpha|^2 - r}{p^2}}$ okay. So this gives you $\text{mod of } z + \frac{\alpha}{p} = \text{square root of mod of } \frac{|\alpha|^2 - r}{p^2}$ okay because left hand side is $\text{mod of } z + \frac{\alpha}{p}$ square okay, p conjugate we are not writing because p is a real number.

So this equation represents a circle with center $-\frac{\alpha}{p}$ and radius square root of mod of $\frac{|\alpha|^2 - r}{p^2}$ okay. So for this circle if we want z_1 and z_2 to be inverse points for this circle, then the condition is this one, this is the condition. We are going to prove that this is the condition for z_1, z_2 to be inverse points of this circle okay. Now let us assume for this on time being that for z_1, z_2 to be inverse points of the circle, the condition is this.

(Refer Slide Time: 07:00)

Inverse points with respect to a circle

Two points P and Q are said to be the inverse points with respect to a circle Γ if they are collinear with the center C and on the same side of it, and if the product of their distances from the center is equal to r^2 where r is the radius of the circle. From the above definition, it follows that every point other than the center of the circle possesses a unique inverse. The center of the circle and the point at infinity are inverse points for the circle. This is also consistent with the condition

$$pz_1\bar{z}_2 + \alpha\bar{z}_2 + \bar{\alpha}z_1 + r = 0 \quad (1)$$

$$\bar{z}_2 = \frac{-\alpha\bar{z}_1 - r}{\alpha + pz_1}$$

$$CP \cdot CQ = r^2$$

$$\text{When } z_1 = -\frac{\alpha}{p}$$

$$\bar{z}_2 = \infty \Rightarrow z_2 = \infty$$

Then from this condition we notice that \bar{z}_2 is $-\alpha\bar{z}_1 - r / (\alpha + pz_1)$ okay. So that when z_1 is $-\alpha/p$, \bar{z}_2 is infinity which says that z_2 is infinity. So the center, center is from the circle this one, center is $-\alpha/p$ okay and when we put $-\alpha/p$ here okay in this condition, then we get for z_1 then we get \bar{z}_2 to be infinity and get $z_2 = \infty$.

So that means that the center $z_1 = -\alpha/p$ and $z_2 = \infty$ are inverse points with respect to the circle $pz_1\bar{z}_2 + \alpha\bar{z}_2 + \bar{\alpha}z_1 + r = 0$. So the condition which we have here, this condition for z_1, z_2 to be inverse points for the circle is consistent with the fact that if the center $-\alpha/p$ and the infinity are also inverse points with respect to this circle okay. So since the center of the circle is $-\alpha/p$ taking $z_1 = -\alpha/p$ in 3 we get \bar{z}_2 equal to infinity and so that z_2 is also equal to infinity.

So that condition now let us prove this condition that z_1, z_2 are inverse points for the circle when we have that condition. So let us prove that.

(Refer Slide Time: 09:06)

$$\begin{aligned}
 & p \bar{z}_1 \bar{z}_2 + \alpha \bar{z}_2 + \alpha \bar{z}_1 + r = 0 \\
 & \text{Circle } p \bar{z} \bar{z} + \alpha \bar{z} + \alpha \bar{z} + r = 0 \\
 & \text{Without any loss of generality, let } p=1 \\
 & \text{then the circle is } z \bar{z} + \alpha \bar{z} + \alpha \bar{z} + r = 0 \\
 & (z+\alpha)(\bar{z}+\alpha) = \alpha^2 - r \\
 & |z+\alpha|^2 = |\alpha|^2 - r \\
 & \Rightarrow |z+\alpha| = \sqrt{|\alpha|^2 - r} \\
 & \text{center } (-\alpha) \\
 & \text{radius} = \sqrt{|\alpha|^2 - r} = r_1 \\
 & |z_1| = |\bar{z}_1| \\
 & r_1^2 = |\alpha|^2 - r \\
 & \text{or } r = |\alpha|^2 - r_1^2 \\
 & (i) \arg(z_1 + \alpha) = \arg(z_2 + \alpha) \\
 & (ii) |z_1 + \alpha| |z_2 + \alpha| = r_1^2 \\
 & \text{from (i)} \arg(z_1 + \alpha) - \arg(z_2 + \alpha) = 0 \\
 & \arg(z_1 + \alpha) + \arg(\bar{z}_2 + \alpha) = 0 \\
 & \arg\{(z_1 + \alpha)(\bar{z}_2 + \alpha)\} = 0 \\
 & \Rightarrow (z_1 + \alpha)(\bar{z}_2 + \alpha) \text{ is real and positive} \\
 & |z_1 z_2| = |z_1| |z_2| \\
 & z_1 \bar{z}_2 + \alpha \bar{z}_2 + \alpha \bar{z}_1 + r = 0 \\
 & z_1 \bar{z}_2 + \alpha \bar{z}_2 + \alpha \bar{z}_1 - r_1^2 = 0 \\
 & z_1 \bar{z}_2 + \alpha \bar{z}_2 + \alpha \bar{z}_1 + r = 0 \\
 & \text{where } r = \alpha^2 - r_1^2 \\
 & (z_1 + \alpha)(\bar{z}_2 + \alpha) = r_1^2 \\
 & \text{from (iii) \& (iv)} \\
 & (z_1 + \alpha)(\bar{z}_2 + \alpha) = r_1^2 \\
 & (z_1 + \alpha)(\bar{z}_2 + \alpha) = r_1^2
 \end{aligned}$$

So p z1 z2 bar+alpha z2 bar we have this condition p z1 z2 bar and then we have alpha z2 bar and then we have alpha bar z1+r=0. This is the condition which we have to prove and the circle is this one pz z bar and then we have alpha z bar+alpha bar z+r=0. So we have to prove that for this circle okay. If z1 and z2 are inverse points, then this condition holds okay. Now without any loss of generality, we can assume that p=1 okay.

Because if p is not equal to 1 we can divide this equation by p and let the coefficient of zz bar=1. So without any loss of generality let us take p=1, then the equation of the circle is zz bar+alpha z bar+alpha bar z+r=0 and this we can write as z+alpha*z bar+alpha bar=alpha alpha bar-r. So this is now mod of z+alpha square=mod of alpha square-r which imply that mod of z+alpha=square root mod of alpha square-r okay.

So center of the circle is at center is at -alpha okay and radius is under root mod of alpha square -r. Now let us take a circle okay. Say this is -alpha center okay, P and Q are these points which are inverse points with respect to the circle. Let us say P is complex number z1 and Q is complex number z2 okay. Then, if P and Q are inverse points with respect to the circle, then P and Q must be on the same side of the center and collinear with the center okay.

So what we have argument of z1+alpha must be same as argument of z2+alpha that is the first condition because they are collinear with center and on the same side of it and moreover that this is let us say C okay. CP*CQ=radius square, so this means that CP that means modulus of z1+alpha*modulus of z2+alpha okay is=radius square. So we have modulus of z1+alpha*modulus of z2+alpha=radius of the circle square.

So that is r^2 okay. So there are two conditions, this is condition number 1, this is condition number 2 okay. Now let us notice that from condition 1, $\arg(z_1 + \alpha) - \arg(z_2 + \alpha) = 0$. Now we can also say that $\arg(z_2 + \alpha) = -\arg(z_2 + \alpha)^{\text{conjugate}}$ okay. If z is any complex number, then $\arg(z)$ is same as $-\arg(z^{\text{conjugate}})$ okay.

So making use of that I can write it as $\arg(z_1 + \alpha) + \arg(z_2 + \alpha)^{\text{conjugate}} = 0$ okay or I can say $\arg(z_1 + \alpha * (z_2 + \alpha)^{\text{conjugate}}) = 0$. Now if \arg of a complex number is 0, it will mean that $z_1 + \alpha * (z_2 + \alpha)^{\text{conjugate}}$ is a real positive number, is real and positive okay. Now $|z_1 + \alpha| * |z_2 + \alpha| = r^2$. The condition 2 gives us $|z_1 + \alpha| = r$, now $|z_2 + \alpha|$ is same as $|z_2 + \alpha|^{\text{conjugate}}$ okay.

So $|z_2 + \alpha|$ is same as $|z_2 + \alpha|^{\text{conjugate}} = r$ or I can say that $|z_1 + \alpha * (z_2 + \alpha)^{\text{conjugate}}| = r^2$ because $|z_1 * z_2| = |z_1| * |z_2|$ okay. So now there is a complex number whose modulus is r^2 and that complex number is real and positive, so from this condition this one this is condition number 3 and this is condition number 4 okay.

From these two conditions, it follows that okay from 3 and 4, here we are saying that $z_1 + \alpha * (z_2 + \alpha)^{\text{conjugate}}$ is real and positive and here its modulus is r^2 . So this complex number itself is r^2 okay. So $z_1 + \alpha * (z_2 + \alpha)^{\text{conjugate}} = r^2$ and this gives you what, $z_1 + \alpha * (z_2 + \alpha)^{\text{conjugate}} + \alpha^{\text{conjugate}} = r^2$.

So then this will be $z_1 z_2^{\text{conjugate}} + \alpha z_2^{\text{conjugate}} + z_1 \alpha^{\text{conjugate}} + z_1 z_2^{\text{conjugate}} + \alpha z_2^{\text{conjugate}} + z_1 \alpha^{\text{conjugate}} + \alpha \alpha^{\text{conjugate}}$ = actually this r should be taken as radius of the circle which I have taken, it should not be taken as r , it should be some r' it will be better because here this r is not the radius of the circle, this r is actually a certain real number and the radius is $\text{mod of } \alpha^2 - r$.

So this r you can write as say r_1 here it will be better okay. So this I can write as r_1 , so then what we will have here r_1^2 okay. So then if we do that so then this will be equal to $z_1 z_2^{\text{conjugate}} + \alpha z_2^{\text{conjugate}} + z_1 \alpha^{\text{conjugate}}$ and then we have $\alpha \alpha^{\text{conjugate}}$

$\overline{z_1}^2 = 0$ and this is then $z_1 \overline{z_2} + \alpha \overline{z_2} + \alpha \overline{z_1} + r = 0$, so this r is where r is your $\alpha \overline{\alpha} - r^2$ okay.

So $\alpha \overline{\alpha} - r^2$ square, so what we are getting $z_1 \overline{z_2}$ okay. P we have taken as 1 so $z_1 \overline{z_2} + \alpha \overline{z_2} + \alpha \overline{z_1} + r = 0$. So this radius of the circle which we are writing here as $\sqrt{\alpha \overline{\alpha} - r}$, this is actually r okay. So r^2 is $\alpha \overline{\alpha} - r$ or we can say $r = \alpha \overline{\alpha} - r^2$ okay, so this r is $\alpha \overline{\alpha} - r^2$ square.

So radius of the circle is r okay and r is $\sqrt{\alpha \overline{\alpha} - r}$, so the condition for the circle $z \overline{z} + \alpha \overline{z} + \alpha \overline{z} + r = 0$ to have the inverse points z_1, z_2 as inverse points is that $z_1 \overline{z_2} + \alpha \overline{z_2} + \alpha \overline{z_1} + r = 0$. So this is how we prove this condition that is $z_1 \overline{z_2} + \alpha \overline{z_2} + \alpha \overline{z_1} + r = 0$ is the condition for the circle $z \overline{z} + \alpha \overline{z} + \alpha \overline{z} + r = 0$ to have the inverse points at z_1 and z_2 .

(Refer Slide Time: 19:36)

Theorem

Under a bilinear transformation

$$w = S(z),$$

inverse points with respect to a circle Γ are mapped onto inverse points with respect to the image of Γ under $S(z)$.

Proof

Let z_1, z_2 be inverse points for the circle Γ given by

$$z \overline{z} + \alpha \overline{z} + \alpha \overline{z} + r = 0 \quad (4)$$

so that we have the condition

$$z_1 \overline{z_2} + \alpha \overline{z_2} + \alpha \overline{z_1} + r = 0. \quad (5)$$

 IIT ROORKEE
  NPTEL ONLINE CERTIFICATION COURSE

5

Now let us go to this theorem which says that under a bilinear transformation $w = Sz$, inverse points with respect to a circle are mapped onto inverse point with respect to the image of the circle Γ under Sz . So let us say z_1, z_2 be inverse points for the circle $z \overline{z} + \alpha \overline{z} + \alpha \overline{z} + r = 0$. Then, we have this condition as we have proved just now $z_1 \overline{z_2} + \alpha \overline{z_2} + \alpha \overline{z_1} + r = 0$.

(Refer Slide Time: 20:10)

Consider now the bilinear transformation

$$w = S(z) = \frac{az + b}{cz + d}, \quad \underline{ad - bc \neq 0}$$

with the inverse transformation

$$z = \frac{-dw + b}{cw - a}$$

Then the transform of (4) is

$$p \left(\frac{-dw + b}{cw - a} \right) \left(\frac{-\bar{d}\bar{w} + \bar{b}}{\bar{c}\bar{w} - \bar{a}} \right) + \alpha \left(\frac{-\bar{d}\bar{w} + \bar{b}}{\bar{c}\bar{w} - \bar{a}} \right) + \bar{\alpha} \left(\frac{-dw + b}{cw - a} \right) + r = 0 \quad (6)$$

Now let us consider the transformation $w = Sz$ to be $az + b/cz + d$ where $ad - bc$ is nonzero. Then, we can write the inverse while in a transformation $z = -dw + b/cw - a$. Let us put the value of z as $-dw + b/cw - a$ in the equation of this one in the condition okay $p z_1 z_2 \text{ conjugate} + \alpha z_2 \text{ conjugate} + \alpha \text{ conjugate } z_1 + r = -0$. So let us put in this and see what is the condition that we get okay.

So then we get p times transform of 4 okay. First, we are transforming the circle okay. First, we are transforming the circle under the bilinear transformation by putting the value of z , so when you put the value of z we get p times $-dw + b/cw - a$ this is the value of z , then $z \text{ conjugate}$. So $-d \text{ conjugate } w \text{ conjugate} + b \text{ conjugate}/c \text{ conjugate } w \text{ conjugate} - a \text{ conjugate}$ because a, b, c, d are complex constants, so we have to take their conjugates here.

So α times $z \text{ conjugate}$ then $\alpha \text{ conjugate } z + r = 0$. So this is the equation that we get under the bilinear transformation $w = Sz$ for the given circle in the w -plane okay.

(Refer Slide Time: 21:30)

Also, the condition (5), when re-written in terms of w_1, w_2 gives

$$p \left(\frac{-dw_1 + b}{cw_1 - a} \right) \left(\frac{-\bar{d}\bar{w}_2 + \bar{b}}{\bar{c}\bar{w}_2 - \bar{a}} \right) + \alpha \left(\frac{-\bar{d}\bar{w}_2 + \bar{b}}{\bar{c}\bar{w}_2 - \bar{a}} \right) + \bar{\alpha} \left(\frac{-dw_1 + b}{cw_1 - a} \right) + r = 0 \quad (7)$$

The condition (7) shows that the points w_1, w_2 are inverse points for the image of Γ given by (6) in the w plane.

o

Now also the condition 5 okay, when the condition 5 is written in terms of w_1, w_2 . So let us see okay so this condition okay. This condition let us write w_1 is the image of z_1 under the bilinear transformation $w=Sz$ and w_2 is the image of z_2 . So we have this transformation p times z_1 then here z_2 conjugate + α times z_2 conjugate + α conjugate $z_2 + r = 0$ and you can see that this condition okay shows that the points w_1, w_2 are inverse points for the image of Γ given by 6 okay.

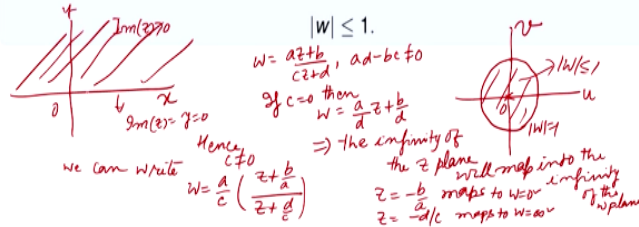

This is the image of Γ okay so when we want to write the condition for w_1, w_2 to be the inverse points with respect to this image, the condition is this one okay so this condition we are using. So this condition you can see we are getting here $p z_1 z_2$ conjugate + αz_2 conjugate + α conjugate $z_1 + r = 0$, it is of that type okay. So this condition tells us that w_1, w_2 are inverse points for the image of the circle under $w=Sz$.

The image is given by the equation 6 okay. So this condition shows that w_1, w_2 are inverse points for the image of Γ under this $w=Sz$.

(Refer Slide Time: 23:06)

Example 1

Find the general bilinear transformation which maps the upper half of the z plane i.e. $\text{Im}(z) \geq 0$ onto the unit circle

Now let us find the general bilinear transformation which maps the half plane upper half plane upper half of z -plane that is imaginary part of $z \geq 0$. So the boundary of the upper half of the z -plane, this is imaginary part of $z > 0$ boundary is real axis okay. On the real axis, imaginary part of $z=0$ which is $y, y=0$ okay so we want to map it onto the unit disk in the w -plane into this region okay.

Now let us consider the general bilinear transformation $w = \frac{az+b}{cz+d}$. We know that it represents a bilinear transformation when $ad-bc$ is not equal to 0, a, b, c, d are any complex constants okay. Now first thing that we notice is that if $c=0$ then ad is not equal to 0, so a and d cannot be 0, so then $w = \frac{a}{d}z + \frac{b}{d}$ we get a linear mapping okay. Under a linear mapping, infinity $z=\infty$ goes to $w=\infty$ okay.

So then this implies that the infinity is in the two planes will correspond. The infinity of the z -plane will map into the infinity of the w -plane okay. So this means that $z=\infty$ of the z -plane will go into infinity so in that case what will happen the imaginary part of $z > 0$ will not be bounded. We want the imaginary part of z to go to a bounded region okay, $\text{mod of } w \leq 1$.

So $\text{mod of } w \leq 1$ is a bounded region and therefore it does not contain infinity $w=\infty$. So $z=\infty$ if goes to $w=\infty$ then the imaginary part of $z \geq 0$ will not be $\text{mod of } w \leq 1$ okay. So hence c cannot be 0 okay. So when c is not equal to 0, we can write $w = \frac{a}{c}z + \frac{b/a}{z+d/c}$ okay. Now let us see this transformation okay. Here what happens is $z = -\frac{b}{a}$ goes to maps into $w=0$ which is the center of the circle $\text{mod of } z=1$ and $z = -\frac{d}{c}$ maps to $w=\infty$ okay.

Now we want the imaginary part of $z > 0$ to map into the interior of $\text{mod of } w = 1$. Now this $w = 0$ and $w = \text{infinity}$ are inverse points with respect to $\text{mod of } w = 1$. So they must be the images of the inverse points with respect to the real axis okay because real axis is the boundary here okay.

(Refer Slide Time: 27:18)

$w = 0$ and $w = \infty$ are inverse points with respect to $|w| = 1$
 $\therefore z = -\frac{b}{a}$ and $z = -\frac{d}{c}$ must be inverse points with respect to the real axis of the z -plane
 If $-\frac{b}{a} = \alpha$ then $-\frac{d}{c} = \bar{\alpha}$
 Since $-\frac{b}{a}$ is mapped to $w = 0$ which lies at the center of $|w| = 1$
 $-\frac{b}{a} = \alpha$ must be a point of $\text{Im}(z) > 0$
 $\Rightarrow \text{Im}(\alpha) > 0$

Now $w = \frac{a}{c} \left(\frac{z-d}{z-\bar{\alpha}} \right)$
 $|w| = 1 \Rightarrow \left| \frac{a}{c} \right| \left| \frac{z-d}{z-\bar{\alpha}} \right| = \left| \frac{a}{c} \right| \frac{|z|}{|z|} = \left| \frac{a}{c} \right| \Rightarrow \left| \frac{a}{c} \right| = 1$
 $\Rightarrow \frac{a}{c} = e^{i\theta_0}$, where θ_0 is real

$w = 0$ and $w = \text{infinity}$ are inverse points with respect to $\text{mod of } w = 1$. So $z = -b/a$ and $z = -d/c$ must be inverse points with respect to the real axis of the z -plane which means that if $z = -b/a$ if this is α if $-b/a = \alpha$ then $-d/c$ must be α conjugate. Now one more thing we notice that $-b/a$ okay, this is z -plane, this is w -plane okay. We have this $\text{mod } w = 1$, so the interior imaginary part of $z > 0$ okay, this we want to map to interior here of $\text{mod of } w = 1$.

And $-b/a$ is going to $w = 0$ okay, this is $w = 0$. So $-b/a$ must be a point of the imaginary part of $z > 0$ okay. So since $-b/a$ is mapped to $w = 0$ which lies at the center of $\text{mod } w = 1$ $-b/a = \alpha$ must be a point of imaginary part of $z > 0$ okay which imply that imaginary part of α must be > 0 okay or imaginary part of $-b/a$ must be > 0 okay. So now we can write $w = a/c * z + b/a / z + d/c$ means $z - \alpha$ and $z + d/c$ means $z - \alpha$ conjugate okay.

So about transformation $w = a/c * z + b/a / z + d/c$ now transforms to $w = a/c * z - \alpha / z - \alpha$ conjugate. Now we want this boundary of the region imaginary part of $z > 0$ to map to the boundary of $\text{mod of } w < 1$. So here boundary is $\text{mod of } w = 1$, here boundary is imaginary part of $z = 0$ that is the x -axis. So let us take the point $z = 0$ on the real axis that $z = 0$ must be mapped onto some point of $\text{mod of } w = 1$.

So $\text{mod of } w=1=a/c$ modulus of $a/c \cdot \text{mod of } z$ you put 0, $0-\alpha/0-\alpha$ conjugate okay. When $z=0$, it should map to some point where $\text{mod of } w=1$. So this is equal to $\text{mod of } a/c$ $\text{mod of } \alpha/\text{mod of } \alpha$ conjugate okay. Now $\text{mod of } z=\text{mod of } z$ conjugate, so $\text{mod of } z$ $\text{mod of } \alpha/\text{mod of } \alpha$ conjugate is 1, so we get $\text{mod of } a/c$ okay. So $1=\text{mod of } a/c$, this imply that a/c is e to the power $i \theta_0$ okay where θ_0 is a real number okay where θ_0 is a real quantity okay.

So we get the most general bilinear transformation that maps the upper half plane into $\text{mod of } w \leq 1$ is $w=e$ to the power $i \theta_0 \cdot z-\alpha/z-\alpha$ conjugate. So this is the transformation which maps the upper half of the z -plane to the unit disk $\text{mod of } w \leq 1$ okay.

(Refer Slide Time: 32:30)

Example 2

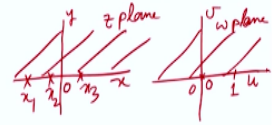

Determine the general bilinear transformation which maps the upper half of the z plane onto the upper half of the w plane.

Solution

A bilinear transformation which maps the real axis in the z -plane on the real axis in the w -plane is such that some three points x_1, x_2, x_3 on the real axis in the z -plane are mapped on $0, 1, \infty$ respectively lying on the real axis in the w -plane. The desired bilinear transformation is given by

$$w = \frac{az + b}{cz + d}$$

where $a, b, c, d \in \mathbb{R}$ and $ad - bc > 0$.

Now we go to the next example determine the general bilinear transformation which maps the upper half of the z -plane onto upper half of w -plane. So here we want the upper half of the z -plane to map to upper half of the w -plane okay. So this is z -plane, this is w -plane, so let us first find the bilinear transformation which maps the real axis of the z -plane to the real axis of the w -plane okay.

So a bilinear transformation which maps the real axis in the z -plane on the real axis of the w -plane is such that some 3 points you take 3 points x_1, x_2, x_3 here, they go to say 3 points, let me take one point 0 and then another point 1 and the third point at infinity okay. So x_1, x_2, x_3 if they map to 0, 1, infinity, we get a unique bilinear transformation which that it is. So let us map these points x_1, x_2, x_3 to 0, 1, infinity okay, x_1, x_2, x_3 are points on real axis x -axis.

And 0, 1, infinity are points on the u-axis, the real axis of w-plane okay. Now let us find the bilinear transformation under which x_1, x_2, x_3 go to 0, 1, infinity.

(Refer Slide Time: 34:00)

we have

$$\frac{z-x_1}{z-x_3} \cdot \frac{z_2-x_3}{z_2-x_1} = \frac{w-w_1}{w-w_3} \cdot \frac{w_2-w_3}{w_2-w_1}$$

$z_1, z_2, z_3 \rightarrow w_1, w_2, w_3$

$$= \lim_{z_2 \rightarrow \infty} \frac{w-w_1}{w-w_3} \cdot \frac{w_2-w_3}{w_2-w_1}$$

$$= \lim_{w_2 \rightarrow \infty} \frac{w-w_1}{w-\frac{1}{w_3}} \cdot \frac{w_2-w_3}{w_2-w_1}$$

$$= \lim_{w_2 \rightarrow \infty} \frac{w-w_1}{w w_3} \cdot \frac{w w_2 - 1}{w_2 - w_1} = \frac{w-w_1}{w_2-w_1} = \frac{w-0}{1-0} = w$$

we have

$$\frac{(z-x_1)(x_2-x_3)}{(z-x_3)(x_2-x_1)} = w = \frac{az+b}{cz+d}$$

where $a = x_2-x_3$
 $b = -x_1(x_2-x_3)$
 $c = (x_2-x_1)$
 $d = -x_3(x_2-x_1)$

Now $ad-bc$

$$= (x_2-x_3) \{-x_3(x_2-x_1)\} - \{-x_1(x_2-x_3)\}(x_2-x_1)$$

$$= (x_2-x_3)(x_2-x_1) \{-x_3+x_1\} = (x_2-x_3)(x_2-x_1)(x_1-x_3) \neq 0$$

because x_1, x_2 and x_3 are distinct

$a, b, c, d \in \mathbb{R}$

So we have the bilinear transformation which maps x_1, x_2, x_3 to w_1, w_2, w_3 that is given by we have $z-x_1/z-x_3$ then z_2-x_3/z_2-x_1 okay. When the z_1, z_2, z_3 are mapped to w_1, w_2, w_3 okay, we know what is the bilinear transformation which does this. So here z_1, z_2, z_3 are x_1, x_2, x_3 . So this is equal to $w-w_1/w-w_3 \cdot w_2-w_3/w_2-w_1$ okay. Now w_1, w_2, w_3 is w_1 is 0, w_2 is 1, w_3 is infinity, so let us find the right hand side cross ratio right hand side it gives us 2.

Limit w_3 goes to infinity, $w-w_1/w-w_3 \cdot w-w_3/w_2-w_1$ okay. So this is equal to limit w_3 goes to 0, $w-w_1/w-1/w_3$ then $w-1/w_3/w_2-w_1$ okay. So this is equal to limit w_3 goes to 0 $w-w_1/ww_3-1 \cdot ww_3-1/w_2-w_1$ okay. So this is equal to $w-w_1/w_2-w_1$, w_1 is 0 okay and $w_2=1$, so $1-0$ so the right hand side is w okay. So we have $z-x_1 \cdot x_2-x_3/z-x_3 \cdot$ this should be x_2-x_1 so $x_2-x_1=w$ okay.

Now this is of the form $az+b/cz+d$ where $a=x_2-x_3$, $b=-x_1 \cdot x_2-x_3$, $c=x_2-x_1$ and $d=-x_3 \cdot x_2-x_1$ okay. Now if we want to say that this is bilinear transformation then we should show that $ad-bc$ is not 0 okay. So $ad-bc$ is how much? So $x_2-x_3 \cdot -x_3 \cdot x_2-x_1 - ad-bc$ okay, so $-x_1 \cdot x_2-x_3$ and then x_2-x_1 , so this is what I can take x_2-x_3 and x_2-x_1 common, then what we get is $-x_3+x_1$ okay. So what we get $x_2-x_3 \cdot x_2-x_1$ and x_1-x_3 and which is not equal to 0.

Because x_1, x_2, x_3 are distinct, they are distinct okay and moreover that we notice that x_1, x_2, x_3 are real numbers, so a, b, c, d belong to \mathbb{R} okay; a, b, c, d belong to \mathbb{R} because x_1, x_2, x_3 are real okay and $ad-bc$ is nonzero okay.

(Refer Slide Time: 39:14)

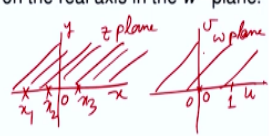

Example 2

Determine the general bilinear transformation which maps the upper half of the z plane onto the upper half of the w plane.

Solution

A bilinear transformation which maps the real axis in the z -plane on the real axis in the w -plane is such that some three points x_1, x_2, x_3 on the real axis in the z -plane are mapped on $0, 1, \infty$ respectively lying on the real axis in the w -plane. The desired bilinear transformation is given by

$$w = \frac{az + b}{cz + d}$$

where $a, b, c, d \in \mathbb{R}$ and $ad - bc > 0$.

NPTEL ONLINE CERTIFICATION COURSE
9

So we get the transformation $w = az + b/cz + d$ where a, b, c, d is not 0 okay where a, b, c, d are real numbers and $ad-bc$ is nonzero. Now let us show that the upper half of the z -plane goes to upper half of the w -plane.

(Refer Slide Time: 39:38)

$$w = \frac{az + b}{cz + d}$$

$$\bar{w} = \frac{a\bar{z} + b}{c\bar{z} + d}$$

$$w - \bar{w} = \frac{az + b}{cz + d} - \frac{a\bar{z} + b}{c\bar{z} + d}$$

$$= \frac{ac z \bar{z} + bc \bar{z} + ad z + bd - ac \bar{z} z - ad \bar{z} - bc \bar{z} - bd}{(cz + d)(c\bar{z} + d)}$$

$$= \frac{(ad - bc)z - (ad - bc)\bar{z}}{|cz + d|^2} = \frac{(ad - bc)(z - \bar{z})}{|cz + d|^2}$$

$$2iV = \frac{(ad - bc)2iy}{|cz + d|^2}$$

$$\text{or } V = \frac{(ad - bc)y}{|cz + d|^2}$$

if $z = x + iy$
 $w = u + iv$
 then
 $z - \bar{z} = 2iy$
 $w - \bar{w} = 2iV$

if $y > 0$ then $V > 0$ provided $ad - bc > 0$
 if $y > 0$ then $V < 0$ provided $ad - bc < 0$

For that we have to consider $w = az + b/cz + d$ okay. So then w conjugate is az conjugate + b/cz conjugate + d okay. We are not taking conjugates of a, b, c, d because they are real. Then w -conjugate = $az + b/cz + d - az$ conjugate + b/cz conjugate + d . So we take the LCM $cz + d$ cz

conjugate+ d and then we get let us multiply, so ac zz conjugate okay then bc z conjugate, then we get ad z and then we get bd okay.

And then we get $-ac$ zz conjugate, then we get $-ad$ z conjugate and then we get $-bc$ z and $-bd$. So this bd cancel out, ac zz conjugate cancel out and what we get, let us collect the coefficient of z and z conjugate. So the coefficient of z is $ad-bc$ okay and z conjugate coefficient is what, $-ad-bc$ z conjugate/now $cz+d$ cz conjugate+ d we can write as mod of $cz+d$ square okay, so this is $ad-bc$ $z-z$ conjugate okay/mod of $cz+d$ square okay.

Now so what we have $w-w$ conjugate is $=ad-bc$ $z-z$ conjugate/mod of $cz+d$ square okay. So if $z=x+iy$ and $w=u+iv$ okay, $w=z$, $z=x+iy$, $w=u+iv$, then $z-z$ conjugate is $2iy$ okay and $w-w$ conjugate is $2iv$ okay. So $2iv=ad-bc$ $2iy$ /mod of $cz+d$ square okay or $v=ad-bc$ y /this. So if y is >0 okay if y is >0 , then v is >0 provided $ad-bc$ is >0 . We can also say that if y is >0 , then v is <0 provided $ad-bc$ is <0 okay.

So the upper half of the z -plane will map to the upper half of the w -plane if $ad-bc$ is >0 and upper half of the z -plane will map to lower half of the w -plane if $ad-bc$ is <0 okay. So the bilinear transformation which maps the upper half of z -plane to the upper half of the w -plane is given by $w=az+b/cz+d$ where a, b, c, d are real numbers and $ad-bc$ is >0 . If you put the condition on a, b, c, d that which they are real and $ad-bc$ is <0 then upper half of the z -plane will map to lower half of the w -plane okay.

So with that we come to the end of this lecture. Thank you very much for your attention.
