**Conformal Mappings from Disk to Disk and Angular Region to Disk**

Hello friends. Welcome to my lecture on conformal mappings from disk to disk and angular region to disk. Here we shall also consider the conformal mapping  $w = \exp z$ . These conformal mappings are required by us when we solve problems arising in potential theory. So let us first consider the general bilinear transformation which transforms the disk  $|z| \leq \rho$  onto the disk  $|w| \leq \rho'$ .

(Refer Slide Time: 00:58)

$|\alpha| \left| \frac{z^2}{\alpha} \right| = K \left| \frac{z^2}{\alpha} \right|$   
 $= \rho^2$

**Example 1**

Determine the general bilinear transformation which transforms the disk  $|z| \leq \rho$  onto the disk  $|w| \leq \rho'$ . (Ans:  $w = \rho \rho' e^{i\theta_0} \left( \frac{z - \alpha}{\alpha z - \rho^2} \right)$ , where  $|\alpha| < \rho$ )

$w = \frac{az+b}{cz+d}$ ,  $ad-bc \neq 0$

If  $c=0$ , then the infinity of the  $z$ -plane would correspond to the infinity of the  $w$ -plane & so we have to consider  $c \neq 0$ .  
 Since  $w=0$  and  $w=\infty$  are inverse points with respect to the circle  $|w|=\rho'$ , the points  $z=-b/a$  and  $z=-d/c$  are inverse points with respect to the circle  $|z|=\rho$ .  
 We may write  $w = \frac{a}{c} \left( \frac{z + \frac{b}{a}}{z + \frac{d}{c}} \right)$   
 $z = -\frac{b}{a}$  is mapped to  $w=0$   
 $z = -\frac{d}{c}$  is mapped to  $w=\infty$   
 Now,  $\alpha = -\frac{b}{a}$  then  $-\frac{d}{c} = \frac{\rho^2}{\alpha}$

So we have the disk in  $z$ -plane which bounds the region  $|z| \leq \rho$  and then we have the disk in the  $w$ -plane given by  $|w| \leq \rho'$ . So let us consider the bilinear transformation  $w = az + b/cz + d$  where  $ad - bc$  is not equal to 0 okay. Now here again we start with the condition on  $c$ . If  $c$  is 0, then the infinity of the  $z$ -plane will correspond to the infinity of the  $w$ -plane.

Then, the infinity of the  $z$ -plane would correspond to the infinity of the  $w$ -plane and so we have to consider  $c$  not equal to 0 okay and when  $c$  is not equal to 0 we may write  $w$  as  $a/c * z + b/a / z + d/c$  okay. Now from here it is clear that  $z = -b/a$  is mapped to  $w = 0$  and  $z = -d/c$  is mapped onto  $w = \infty$ . Now we know that  $w = 0$  and  $w = \infty$  are inverse points with

respect to circle mod of  $w=\rho$  dash. So since  $w=0$  and  $w=\infty$  are inverse points with respect to the circle mod of  $w=\rho$  dash.

And under bilinear transformation, inverse points with respect to a circle are mapped into inverse points with respect to its image. So these points 0 and infinity should correspond to the inverse points  $-b/a$  and  $-d/c$  with respect to the circle mod of  $z=\rho$ . So therefore so the points  $z=-b/a$  and  $z=-d/c$  okay are inverse points with respect to the circle mod of  $z=\rho$  okay. Now let us say let  $\alpha$  be  $-b/a$ .

Then,  $-d/c$  will be  $\rho^2/\alpha$  conjugate because  $-b/a$  and  $-d/c$  are inverse points with respect to the circle mod of  $z=\rho$ . So  $\alpha$  and its inverse point  $\rho^2/\alpha$  conjugate they must be on the same side of the center and they should be collinear with the center okay, so one point if it is here, the other point will be here. So they are collinear with the center and on the same side of it.

And moreover product of the distances with the center is  $=$  radius square. So here you can see if argument of  $\alpha$  is  $\theta$  then argument of  $\rho^2/\alpha$  conjugate is also  $\theta$  and moreover modulus of  $\alpha \cdot \text{modulus of } \rho^2/\alpha$  conjugate is  $=$  modulus of  $\alpha$ . If it is  $\alpha$  the other  $-d/c$  is  $= \rho^2 \cdot \alpha$  conjugate. So what we have, the product of the two must be equal to  $\rho^2$ , the product of the moduli of the two.

So if modulus of  $\alpha \cdot \text{modulus of } \rho^2/\alpha$  conjugate okay is  $=$  modulus of  $\alpha \cdot \rho^2/\text{modulus of } \alpha$  conjugate. So these two cancel and we get  $\rho^2$  okay. So if  $-b/a$  is  $= \alpha$  then  $-d/c$  must be equal to  $\rho^2/\alpha$  conjugate. Now we notice that  $\alpha = -b/a$  is mapped to the interior of mod of  $w=\rho$  dash that is it is mapped to  $w=0$ , so  $-b/a$  okay must be such that modulus of  $\alpha$  should be  $< \rho$ , it should be an interior point of mod of  $z=\rho$  okay.

**(Refer Slide Time: 07:33)**

Since  $\alpha = -\frac{b}{a}$  is mapped onto  $w=0$  which lies at the center of mod of  $w=\rho$  dash.

of  $|w|=\rho'$  hence  $|\alpha| < \rho$

Thus  $w = \frac{a}{c} \frac{z-\alpha}{z-\rho^2} = \frac{a\bar{\alpha}}{c} \frac{z-\alpha}{z-\rho^2}$  (1)

Now  $|z|=\rho$  must be mapped onto  $|w|=\rho'$  so

Thus (1) becomes  $w = \frac{\rho \rho' e^{i\theta_0} (z-\alpha)}{z-\rho^2}$  where  $\theta_0$  is real and  $|\alpha| < \rho$

If  $|z|=\rho$  then  $z\bar{z}=\rho^2$  & so

$|w| = \left| \frac{a\bar{\alpha}}{c} \right| \left| \frac{z-\alpha}{z-\rho^2} \right|$

Since  $|w|=\rho'$ , we have

$\rho' = \left| \frac{a\bar{\alpha}}{c} \right| \frac{1}{\rho}$  or  $\left| \frac{a\bar{\alpha}}{c} \right| = \rho \rho' \Rightarrow \frac{a\bar{\alpha}}{c} = \rho \rho' e^{i\theta_0}$  for some  $\theta_0 \in \mathbb{R}$

Since  $\alpha = -b/a$  is mapped onto  $w=0$  okay which lies at the center of mod of  $w=\rho$  dash. Hence, mod of  $\alpha$  must be  $< \rho$ , it must be an interior point of the circle mod of  $z=\rho$  okay. Now what do we get, we have  $w = a/c \frac{z+b/a}{z+d/c}$  and  $b/a$  is  $-\alpha$ ,  $d/c$  is  $-\rho^2/\alpha$  conjugate, so let us put these values. So we get thus  $w = a/c \frac{z+b/a}{z-\rho^2/\alpha}$  and  $z+d/c$  is  $z-\rho^2/\alpha$  conjugate okay.

So this we can write as  $a/c * z - \alpha/\alpha$  conjugate  $z-\rho^2$  square and then  $\alpha$  conjugate here okay. So we can put it like this. So now we want to map the boundary of the disk in the  $w$ -plane to the boundary of the disk in the  $w$ -plane okay. Modulus of  $z=\rho$  should be mapped to modulus of  $w=\rho$  dash. So let us take a point on the boundary. Let us take a point. So what we get?

Okay now mod of  $z=\rho$  must be mapped onto mod of  $w=\rho$  dash, so mod of  $w$  we can take here this equation let we call it as 1. So mod of  $w = \text{mod of } a \alpha \text{ conjugate}/c * \text{mod of } z - \alpha/\alpha \text{ conjugate } z-\rho^2$  square okay. So if  $z$  lies on the boundary mod  $z=\rho$  if mod of  $z=\rho$  then  $z\bar{z}$  conjugate is  $\rho^2$  square and so mod of  $w$  will be  $\text{mod of } a \alpha \text{ conjugate}/c * \text{mod of } z - \alpha/\alpha \text{ conjugate } z-\rho^2$  square okay.

And I can write it as  $\text{mod of } a \alpha \text{ conjugate}/c * \text{mod of } z - \alpha/\alpha$  conjugate  $z$ , this is  $z\bar{z}$  conjugate okay. So we will write it as  $z$  times  $\alpha$  conjugate  $z$  conjugate okay. Mod of  $z=\rho$  so mod of  $a \alpha \text{ conjugate}/c$  okay  $* \text{mod of } z - \alpha/\rho$  times mod of now  $\alpha$  conjugate  $z$  conjugate is  $\alpha - z$  conjugate okay and mod of  $z - \alpha$  is same as mod of  $\alpha - z$  conjugate.

So these two cancel okay and we get  $\text{mod of } \alpha \text{ conjugate}/c \cdot 1/\rho = \text{mod of } w$ ,  $\text{mod of } w = \rho$  dash okay. So since  $\text{mod of } w = \rho$  dash we have  $\rho \text{ dash} = \text{mod of } \alpha \text{ conjugate}/c \cdot 1/\rho$  or  $\text{mod of } \alpha \text{ conjugate}/c = \rho \rho \text{ dash}$  okay. So thus transformation 1 becomes thus 1 becomes  $w = \rho \rho \text{ dash} \cdot e^{i \theta_0} \cdot z^{-\alpha/\alpha \text{ conjugate}} \cdot z^{-\rho \text{ square}}$  okay where  $\theta_0$  is real and  $\text{mod of } \alpha$  is  $< \rho$  okay.

So this implies that  $\alpha \text{ conjugate}/c = \rho \rho \text{ dash} \cdot e^{i \theta_0}$  for some  $\theta_0$  which is real belonging to  $\mathbb{R}$  okay. So under the transformation  $w = \rho \rho \text{ dash} \cdot e^{i \theta_0} \cdot z^{-\alpha/\alpha \text{ conjugate}} \cdot z^{-\rho \text{ square}}$  where  $\theta_0$  is real and  $\text{mod of } \alpha$  is  $< \rho$ . The disk  $\text{mod of } z \leq \rho$  in the  $z$ -plane will be mapped onto the disk  $\text{mod of } w \leq \rho \text{ dash}$  in the  $w$ -plane, so this is the transformation.

(Refer Slide Time: 13:53)

**Mapping of angular regions onto the unit disk**

Such mappings may be obtained by combining linear fractional transformations and transformations of the form  $w = z^n$ ,  $n$  being an integer  $> 1$ .

**Example**

Map the angular region  $D: -\frac{\pi}{6} \leq \arg z \leq \frac{\pi}{6}$  onto the unit disk  $|w| \leq 1$ .

Let us consider the transformation  $t = z^3$   
 $Re^{i\phi} = r e^{i\theta} \Rightarrow R = r, \phi = 3\theta$  given that  $-\frac{\pi}{6} \leq \theta \leq \frac{\pi}{6} \Rightarrow -\frac{\pi}{2} \leq \phi \leq \frac{\pi}{2}$

3

Now let us go to another case where we have to map an angular region onto the unit disk. Such mappings can be obtained by combining the linear fractional transformations and transformation of the form  $zw = z$  to the power  $n$  where  $n$  is an integer  $> 1$ . Let us say for example you want to map the angular region  $-\pi/6 \leq \text{argument of } z \leq \pi/6$  onto the unit disk  $\text{mod of } w \leq 1$ .

Then, let us draw the figure first. So this is the angular region in the  $z$ -plane okay. This is also  $\pi/6$ , so this is the angular region in the  $z$ -plane and we want to map it to the unit disk in the  $w$ -plane  $\text{mod of } w = 1$  okay. This is where we want to map okay. So what we do is first we will

map this angular region to the right half plane okay. Let us consider the transformation  $t = z$  cube, so we will go from the z-plane to the t-plane okay.

Under this transformation if you say that  $t$  is  $R e^{i\phi}$  and  $z = r e^{i\theta}$  then what we get  $R = r$  and  $\phi = 3\theta$  okay. So here we are given that  $\theta$  lies between  $-\pi/6$  to  $\pi/6$ , so  $3\theta$  will lie in the region  $-\pi/2$  to  $\pi/2$ . So this implies that  $-\pi/2 \leq \phi \leq \pi/2$  okay. So in the t-plane okay this angular region will be mapped into the right half plane. This is t-plane okay. So let us say the real axis is  $\zeta$  and the imaginary axis is  $\eta$  okay.

So in the t-plane okay, the angular region  $-\pi/6 \leq \theta \leq \pi/6$  is mapped onto right half plane. Now from right half plane we will go to the unit disk. So let us recall how we can do that.

**(Refer Slide Time: 17:00)**

Thus the transformation which maps the right half of the t-plane onto the unit disk is given by  $w = i \frac{z-1}{z+1}$

Since  $t = z^3$  we get  $w = \frac{i(z^3-1)}{(z^3+1)}$

$w = \frac{a}{c} \frac{z-1}{z+1}$

$\Rightarrow w = e^{i\theta_0} \frac{z-1}{z+1}, \operatorname{Re}(z) > 0$

Let us take  $\alpha = 1$

$w = e^{i\theta_0} \frac{z-1}{z+1}$

Thus, we have  $w = i \frac{z-1}{z+1}$

$-i = e^{i\theta_0} \frac{0-1}{0+1} = -e^{i\theta_0}$

$e^{i\theta_0} = i$

$\Rightarrow \theta_0 = \frac{\pi}{2}$

Let  $\alpha = -\frac{b}{a}$

$-\alpha = -\frac{d}{c}$

$\Delta$  thus  $w = \frac{a}{c} \frac{z-1}{z+1}$

$|w| = \left| \frac{a}{c} \right| \left| \frac{z-1}{z+1} \right|$

$\Rightarrow 1 = \left| \frac{a}{c} \right| \left| \frac{0-1}{0+1} \right|$

$\Rightarrow 1 = \left| \frac{a}{c} \right|$

$\Rightarrow \frac{a}{c} = e^{i\theta_0}$  where  $\theta_0 \in \mathbb{R}$

Let  $w = \frac{az+b}{cz+d}$

If  $c=0$  then  $z \rightarrow \infty$  will map onto  $w = \infty$

$c \neq 0$

$w = \frac{a}{c} \frac{z + \frac{b}{a}}{z + \frac{d}{c}}$

$z = -\frac{b}{a}$  maps onto  $w = 0$

$z = -\frac{d}{c}$  maps onto  $w = \infty$

So our problem is now to map the right half plane to the disk mod of  $w \leq 1$  okay. Now we can easily do this. Suppose we have let us recall the transformation instead of t-plane we are considering w-plane. So let us say we are mapping from w-plane we are getting this w-plane okay, so this is  $0, x, y$ , this is z-plane and we want to map z-plane to w-plane. Later, we shall replace the z-plane by t-plane.

For convenience, we can do this okay. So let us say we want to map this right half plane into the disk mod of  $w \leq 1$  okay. So we can see that the bilinear transformation  $w = az + b/cz + d$  okay. Now here if  $c$  is  $0$  then  $z = \text{infinity}$  will map onto  $w = \text{infinity}$  but what we want, we want to map unbounded region into the bounded region, so infinity of the z-plane will go to some point in the disk mod of  $w \leq 1$ , so we cannot allow this  $z = \text{infinity}$  to go to  $w$  to infinity.

And therefore  $c$  is not equal to 0 okay, so  $c=0$  is not possible, so  $c$  is not equal to 0 we have to take. Then, we can write  $w = \frac{a}{c} \frac{z+b/a}{z+d/c}$  okay. Now  $z = -b/a$  goes to maps onto  $w=0$  and  $z = -d/c$  maps onto  $w=\infty$ ,  $w=0$  and  $w=\infty$  are inverse points with respect to mod of  $w=1$ , so  $-b/a$ ,  $-d/c$  must be inverse points with respect to the imaginary axis okay. So let us say let  $\alpha = -b/a$ , then  $-d/c$  will be  $-\alpha$  conjugate.

Because if we take any complex number here say  $\alpha$  okay, then its complex conjugate is  $\alpha$  conjugate but its image in the imaginary axis is  $-\alpha$  conjugate okay. So  $-\alpha$  conjugate will be  $-d/c$  and thus  $w = \frac{a}{c} \frac{z-\alpha}{z+\alpha \text{ conjugate}}$  we have okay. This becomes this okay. Now we want to map a point of the right half of the  $z$ -plane into the interior of mod of  $w=1$ .

So let us take okay we want to map the boundary of this region that is the imaginary axis onto mod of  $w=1$ , so let us take  $z=0$  here,  $z=0$  must go to some point on the boundary of the disk that is mod of  $w=1$ . So mod of  $w = \text{mod of } \frac{a}{c} \frac{z-\alpha}{z+\alpha \text{ conjugate}}$  will give you mod of  $w=1$ , so  $1 = \text{mod of } \frac{a}{c} \frac{z-\alpha}{z+\alpha \text{ conjugate}}$  is 0,  $0 = \frac{a}{c} \frac{-\alpha}{\alpha \text{ conjugate}}$  okay. So this implies  $1 = \text{mod of } \frac{a}{c}$  because mod of  $\alpha$  and mod of  $\alpha$  conjugate is same okay.

So this means that  $\frac{a}{c} = e^{i\theta}$  where  $\theta$  is real okay. So this we can say that  $w = \frac{a}{c} \frac{z-\alpha}{z+\alpha \text{ conjugate}}$  this becomes  $w = e^{i\theta} \frac{z-\alpha}{z+\alpha \text{ conjugate}}$ . So this is the most general bilinear transformation which maps the right half of the  $z$ -plane onto the disk mod of  $w \leq 1$ . Now we can get a specific transformation from here.

Here the condition on  $\alpha$  is that  $\alpha$  lies in the right half plane, that means real part of  $\alpha$  must be  $>0$  okay. So that condition we have to have on  $\alpha$  okay because this  $\alpha = -b/a$  goes to  $w=0$ . So  $\alpha$  must be a point of the right half plane. Right half plane is mapped into mod of  $w < 1$  and the boundary that is the  $y$ -axis is mapped onto mod of  $w=1$ , so this condition we will have on  $\alpha$ .

Now we want a specific transformation here. So let us take  $\alpha=1$ . This is most general bilinear transformation. We can take a particular case here, particular transformation we can find. So let us take  $\alpha=1$  then the real part of  $\alpha$  is 1 okay. So it is  $>0$  and  $w$  becomes  $e^{i\theta}$

to the power  $i\theta$   $z^{-1}/z+1$  okay because  $\alpha$  is real it is  $=1$  okay. Now what we do? Let us map a point in order to determine this  $\theta$ , we have to map a point on the  $y$ -axis that is the boundary of the  $z$ -plane onto some point particular point of the mod of  $w=1$ .

So let us say suppose I map  $z=0$  to this  $-i$  okay. We can take any point, so  $-i=e^{i\theta}$  to the power  $i\theta$   $0-1/0+1$ . So this is  $-e^{i\theta}$  to the power  $i\theta$  okay. So  $e^{i\theta}$  to the power  $i\theta$   $0=i$  which implies that  $\theta=\pi/2$  okay. So here I have mapped  $w=0$  onto this point  $-i$  okay in the  $w$ -plane okay. So thus we get the transformation, thus we have  $w=i$  times  $z^{-1}/z+1$ . This transformation maps the right half of the  $z$ -plane to the disk mod of  $w\leq 1$ .

Now I am finding this transformation for the  $t$ -plane, the right half of the  $t$ -plane to map to mod of  $w\leq 1$ . So instead of  $z$ , I will write now  $t$  okay. So thus the transformation which maps right half of the  $t$ -plane onto mod of  $w\leq 1$  is given by  $w=i$  times  $t^{-1}/t+1$  okay. Now we have  $t=z^3$  okay,  $t=z^3$  so let us put that value of  $t$  here. So since  $t$  is  $=z^3$ , we get  $w=i$  times  $z^3$  cube  $-1/z^3$  cube  $+1$  okay.

So this is the desired transformation. The transformation  $w=i$  times  $z^3$  cube  $-1/z^3$  cube  $+1$  maps the angular region  $-\pi/6 \leq \arg z \leq \pi/6$  onto the disk mod of  $w\leq 1$ .

(Refer Slide Time: 26:04)

**Mapping by other functions:**

**The exponential function:**  
 Let us consider  $w = e^z$ . Since  $\frac{dw}{dz} = e^z \neq 0$ , for any  $z \in \mathbb{C}$ ,  $e^z$  is conformal in the whole complex plane. Let us set  $w = Re^{i\phi}$  and  $z = x + iy$  then,  $R = e^x$ ,  $\phi = y$ . ✓  
 Hence the lines  $x = a = \text{constant}$  are mapped onto the circles  $R = e^a$  and lines  $y = c$  are mapped onto the rays  $\phi = c$ . Since  $e^z \neq 0$  for all  $z$ , the point  $w = 0$  is not the image of any point  $z$ .

 NPTEL ONLINE  
 CERTIFICATION COURSE

4

Now let us go to some other mappings which are important when we discuss the applications of conformal mappings. So the mapping that is  $w=e^z$  to the power  $z$ , the exponential function is one such mapping which is important. So the exponential function  $w=e^z$  to the power  $z$  we

know is a conformal mapping for all values of  $z$  belonging to the complex plane because  $dw/dz$  is  $e$  to the power  $z$  and  $e$  to power  $z$  does not vanish for any value of  $z$ .

So  $e$  to the power  $z$  is conformal in the whole complex plane and if you take  $w = Re^{i\phi}$  and  $z = x + iy$  then what we get,  $Re^{i\phi} = e$  to the power  $x + iy$  which we can write as  $e$  to the power  $x * e$  to the power  $iy$  and so equating the absolute values, we get  $R = e$  to the power  $x$  and  $\phi = y$  okay. So  $R = e$  to power  $x$  and  $\phi = y$  hence the lines  $x = a$ . If you take the lines in the  $z$ -plane parallel to  $y$ -axis say  $x = a$  in the  $z$ -plane, then the line  $x = a$  will be mapped onto the circle given by  $R = e$  to the power  $a$ .

$R$  is the radius; it is the radius of the actually  $R = \text{constant}$  gives us the circle in the  $w$ -plane. So this is  $R = e$  to the power  $a$  this is the circle which is having radius  $e$  to the power  $a$  okay. So the equation of the circle is  $\text{mod of } w = e$  to the power  $a$  sorry  $e$  to the power  $a$  okay. So  $x = a$  is mapped into  $\text{mod of } w = e$  to power  $a$ , so the lines are mapped the straight lines which are parallel to  $y$ -axis are mapped onto to circles  $R = e$  to power  $a$ .

And the lines  $y = c$  if you take a line parallel to  $x$ -axis  $y = c$  then you can see  $y = c$  gives you  $\phi = c$  and the  $\phi$  is the argument of  $w$ . So this implies argument of  $w = \text{constant}$ . Argument of  $w = \text{constant}$  means the lines parallel to the real axis of the  $z$ -plane they are mapped onto the ray okay because for the ray argument of  $w$  is constant okay. So this is the argument of  $w$  that is we are taking as  $\phi$  okay.

This is equal to  $\phi$ . So this  $\phi$  is constant, so  $y = c$  is mapped onto the ray  $\phi = c$ . Now  $e$  to the power  $z$  is not 0 for any value of  $z$  that means  $w \neq 0$ , this  $w \neq 0$  is not the image of any point  $z$  in the  $z$ -plane okay.

**(Refer Slide Time: 29:20)**

### Mapping by other functions cont...

A rectangular region  $a \leq x \leq b, c \leq y \leq d$  is mapped onto the region  $e^a \leq R \leq e^b, c \leq \phi \leq d$ , bounded by rays and circles.

Now let us look at the mapping of a rectangular region in the  $z$ -plane. So let us take a rectangular region in the  $z$ -plane. It is given by  $a \leq x \leq b, c \leq y \leq d$  okay. So this rectangular region now this rectangular region is bounded by  $x=a, x=b$ , so  $x=a$  goes to  $R=e^a$ ,  $x=b$  goes to  $R=e^b$ , therefore the region which is bounded by  $a \leq x \leq b$  goes to  $e^a \leq R \leq e^b$ .

And  $c, y=c$  goes to  $\phi=c$ ,  $y=d$  goes to  $\phi=d$ , so  $c \leq y \leq d$  goes to  $c \leq \phi \leq d$ . So this rectangular region okay goes to the region bounded by the rays and circles, rays are this, this  $x=a$  goes to  $\phi=c$ ,  $x=b$  goes to this  $R=e^a$  to the power  $a$  this circle okay. This is the image of  $x=a$  and this is the image of  $x=b$ , the ray  $R=e^b$  to the power  $b$  and the line  $y=c$  this  $y=c$  goes to  $\phi=c$  and  $y=d$  goes to  $\phi=d$  okay.

So  $a, b$  goes to this  $A^*, B^*$  and  $c, d$  goes to this one,  $d$  becomes  $D^*$  here okay because  $a, d$  goes to this  $R=e^a$  to the power  $a$  okay. So this is  $C^*$ , this is  $D^*$ , so this is the region okay which is the image of this region okay under this  $w=e^z$ .

**(Refer Slide Time: 31:17)**

### Mapping by other functions cont...

The fundamental strip  $-\pi < y \leq \pi$  is mapped onto the full  $w$ -plane (cut along the negative real axis). More generally, every horizontal strip bounded by two lines  $y = c$  and  $y = c + 2\pi$  is mapped onto the full  $w$ -plane. Hence the function  $w = e^z$  is periodic with period  $2\pi i$ .

The horizontal strip  $0 \leq y \leq \pi$  is mapped onto the upper half of the  $w$ -plane. The boundary  $y = 0$  is mapped onto the positive half of the  $u$ -axis and the line  $y = \pi$  onto the negative half of the  $u$ -axis.

Now let us take the fundamental strip  $-\pi < y \leq \pi$  okay. So this fundamental strip let us consider okay this goes to yeah  $y = \phi$ ,  $y = \text{argument of } w$  okay. So if  $y$  lies in  $-\pi$  and  $\pi$ , argument of  $w$  lies from  $-\pi$  to  $\pi$  okay and this means that this fundamental strip is mapped onto the full  $w$ -plane and there is a cut along the negative real axis. More generally every horizontal strip bounded by two lines  $y = c$  and  $y = c + 2\pi$  will be mapped onto full  $w$ -plane.

Because  $y$  is argument of  $w$ , so argument of  $w$  will vary from  $c$  to  $c + 2\pi$  okay, that will cover the whole  $w$ -plane. So hence the function  $w = e^z$  is periodic with period  $2\pi i$ . This we can see directly also  $w = e^z$  to the power  $z$  gives you  $e$  to the power  $z + 2\pi i = e^z \cdot e^{2\pi i} = e^z \cdot 1 = e^z$  okay and  $e$  to power  $2\pi i$  is  $\cos 2\pi + i \sin 2\pi$  which is 1. So  $e$  to the power  $z + 2\pi i$  is  $e^z$  for all  $z$  belonging to the complex plane okay for all complex number  $z$ .

So  $e^z$  is periodic with period  $2\pi i$ . The horizontal strip  $0 \leq y \leq \pi$  let us consider. So the horizontal strip this is  $y = 0$  and this is  $y = \pi$ . So the horizontal strip  $0 \leq y \leq \pi$  is mapped onto the upper half of the  $w$ -plane because then the argument will vary from argument of  $w$  will vary from 0 to  $\pi$ . So argument of  $w$  will vary from 0 to  $\pi$  that means  $\phi$  varies from 0 to  $\pi$  okay.

So it is mapped over here okay. The boundary  $y = 0$  okay  $y = 0$  boundary of the strip is mapped onto positive  $x$ -axis okay, positive  $u$ -axis this is because we are here in the  $w$ -plane, so positive  $u$ -axis and the line  $y = \pi$  is mapped onto negative half of the  $u$ -axis.

### Mapping by other functions cont...

The segment from 0 to  $\pi i$  is mapped onto the semicircle  $|w| = 1, v \geq 0$ . The left half of our strip is mapped onto the region  $|w| \leq 1, v \geq 0$  and the right half ( $x \geq 0$ ) of the strip onto the exterior of the circle  $|w| = 1$  in the upper half of the  $w$ -plane.

The segment from 0 to  $\pi i$  let us look at the segment from 0 to  $\pi i$  this segment okay. The segment from 0 to  $\pi i$ , so this segment from 0 to  $\pi i$  is mapped onto the semicircle mod of  $w=1$ , let us see how we get this because we have looked at the boundary only okay. We have seen that  $y=0$  is mapped onto to positive  $u$ -axis,  $y=\pi$  maps onto negative  $u$ -axis okay. Let us look at where the interior of this strip goes.

(Refer Slide Time: 34:44)

### Mapping by other functions cont...

The fundamental strip  $-\pi < y \leq \pi$  is mapped onto the full  $w$ -plane (cut along the negative real axis). More generally, every horizontal strip bounded by two lines  $y = c$  and  $y = c + 2\pi$  is mapped onto the full  $w$ -plane. Hence the function  $w = e^z$  is periodic with period  $2\pi i$ .

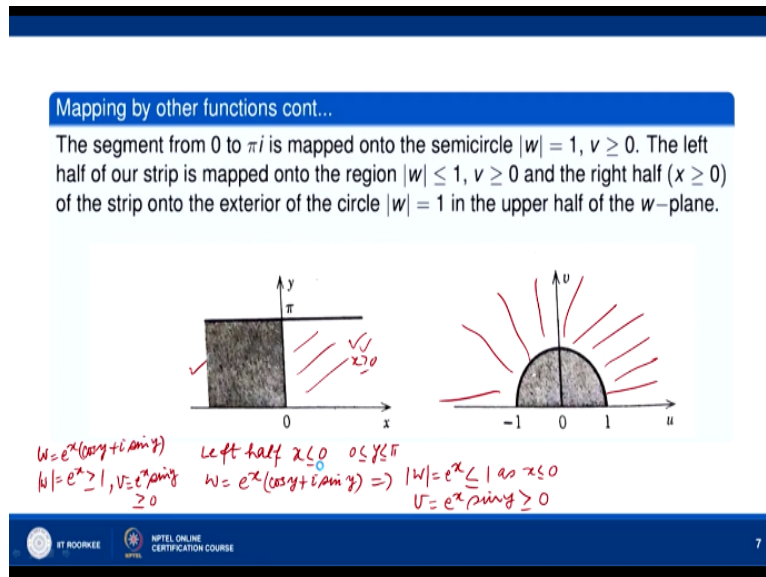

The horizontal strip  $0 \leq y \leq \pi$  is mapped onto the upper half of the  $w$ -plane. The boundary  $y = 0$  is mapped onto the positive half of the  $u$ -axis and the line  $y = \pi$  onto the negative half of the  $u$ -axis.

So let us first look at the segment from 0 to  $\pi i$  along the  $y$ -axis okay. This  $\pi i$  here okay so here along this segment  $x=0$   $y$  varies from 0 to  $\pi$ . So now  $w=e$  to the power  $z$  okay, so this is  $e$  to the power  $x \cdot \cos y + i \sin y$  okay. Now  $x=0$ , so  $w=\cos y + i \sin y$  and this gives you mod of  $w=1$  and  $v=\sin y$  equating real imaginary parts,  $w=u+iv$ ,  $w=u+iv=\cos y + i \sin y$  gives you  $v=\sin y$ .

Now  $y$  varies from 0 to  $\pi$ , so  $\sin y \geq 0$  and therefore the segment 0 to  $\pi i$  is mapped onto  $\text{mod of } w=1$  and  $v \geq 0$ .

(Refer Slide Time: 35:48)

So the segment from 0 to  $\pi i$  is mapped onto the semicircle  $\text{mod of } w=1, v \geq 0$ . The left half of our strip, the left half of the strip this one okay, this left half, this one okay, the left half of the strip let us see where does this go okay. The left half of the strip means this portion okay, this portion shaded portion. So in this part what happens is  $x$  is negative in the left half,  $x \leq 0$  and  $0 \leq y \leq \pi$  okay.

Now  $w = e$  to the power  $x \cos y + i \sin y$  okay. So  $\text{mod of } w$  is  $e$  to the power  $x$  okay. Now  $x \leq 0$ , so  $\text{mod of } w$  is  $\leq 1$  okay. So left half is mapped onto the region  $\text{mod of } w \leq 1$  and  $v \geq 0$  again because  $v$  is  $e$  to the power  $x \sin y$ . When  $x$  is a real number,  $e$  to power  $x$  is always  $\geq 0$  and  $\sin y$  is positive because  $0 \leq y \leq \pi$  so  $v \geq 0$ . So left half of the strip goes to  $\text{mod of } w \leq 1, v \geq 0$ .

That means that the shaded region goes to this shaded region here okay which is defined by  $\text{mod of } w \leq 1$  and  $v \geq 0$  and let us now look at the image of the right half of the strip that is  $x \geq 0$ . So when  $x \geq 0$  what happens, again  $w = e$  to the power  $x \cos y + i \sin y$ , so  $\text{mod of } w = e$  to the power  $x$  and  $x \geq 0$  here okay,  $x \geq 0$  so this is  $\geq 1$ , so  $\text{mod of } w \geq 1$  and  $v$  is  $e$  to the power  $x \sin y$  okay.

So  $v \geq 0$  because  $x$  is real number and  $0 \leq y \leq \pi$ , so  $\text{mod of } w \geq 1$  and  $v \geq 0$  that means the right half of the strip between  $y=0$  to  $y=\pi$  is mapped into this portion okay and

thus the region bounded by this one  $0 \leq y \leq \pi$  is mapped onto the upper half of the  $w$ -plane.  
So with this I would like to end my lecture. Thank you very much for your attention.
