Lecture – 33
Review of Z-transforms - I

Hello friends. Welcome to my lecture on Review of Z-transforms. In this lecture, we shall discuss Z-transforms and their properties.

(Refer Slide Time: 00:40)

The Z-transform of sequences

Laplace transforms are used extensively to analyze continuous-time(analog) signals as well as systems that process continuous-time signals. The Laplace transform is used to represent a large class of continuous-time signals as a superposition of many simpler signals, sometimes called "basis function" or "kernels".

IIIT Roorkee IITEL ONLINE CERTIFICATION COURSE 2

Let us first discuss the Laplace transform because Z-transform is a discrete analog of Laplace transforms. Laplace transforms are used extensively to analyse continuous time analog signals as well as systems that process continuous time signals. The Laplace transform is used to represent a large class of continuous time signals as a superposition of many simpler signals, sometimes called basis function or kernels.

The Z-transform of sequences cont...

For signals that are zero, for negative time, the Laplace formula given by

$$X(s) = \int_{-\infty}^{\infty} x(t)e^{-st} dt.$$

is taken over positive time, giving the one sided, or unilateral Laplace transform,

$$X(s) = \int_0^{\infty} x(t)e^{-st} dt.$$

For signals that are 0, for negative time, the Laplace formula given by $X(s) = \int_{-\infty}^{\infty} x(t)e^{-st} dt$ is taken over positive time, giving the one sided or unilateral Laplace transform $X(s) = \int_0^{\infty} x(t)e^{-st} dt$.

The Z-transform of sequences cont...

For many linear time-invariant(LTI) continuous-time systems, the relationship between the input and output signals can be expressed in terms of linear constant coefficient differential equations. The one sided Laplace transform is a useful tool for solving these differential equations. For such systems, the Laplace transform of the input signal and that of output signal can be expressed in terms of a "transfer function" or "system function".

For many linear time invariant continuous time systems, the relationship between the input and output signals can be expressed in terms of linear constant coefficient differential equations. The one sided Laplace transform is a useful tool for solving these differential equations. For such systems, the Laplace transform of the input signal and that of output signal can be expressed in terms of a transfer function or system function.

(Refer Slide Time: 02:06)

The Z-transform of sequences cont...

Many of the properties such as causality or stability of LTI system can be easily explored by considering the system function of the continuous-time system. Another property of the Laplace transform is that it maps the convolution relationship between the input and output signals in the time domain to a conceptually simpler multiplicative relationship.

Many of the properties such as causality or stability of LTI system that is a linear time invariant system can be easily explored by considering the system function of the continuous time system. Another property of the Laplace transform is that it maps the convolution relationship between the input and output signals in the time domain to a conceptually simpler multiplicative relationship.

The Z-transform of sequences cont...

For discrete time signals, an analogous relationship is developed between signals and systems using the z-transform. The discrete time complex exponential signal, z^n , where z is a complex number, plays a similar role to the continuous-time complex exponential signal e^{st} . Discrete time signals of this form play an important role in the analysis of linear, constant coefficient difference equations.

For discrete time signals, an analogous relationship is developed between signals and systems using the z-transform. the discrete time complex exponential signal, z to the power n , where z is a complex number, plays a similar role to the continuous time complex exponential signal e to the power st . Discrete time signals of this form play an important role in the analysis of linear,

constant coefficient difference equations.

The Z-transform of sequences cont...

Z-transform is a valuable tool for the analysis of discrete time signals and systems. As with Laplace transform, the z-transform is a function of a complex variable. The transform itself can also take on complex values. Hence it is a complex function of a complex variable.

7

Z-transform is a valuable tool for the analysis of discrete time signals and systems as with the case of Laplace transform, the Z-transform is a function of a complex variable. The transform itself can also take on complex values. hence it is a complex function of a complex variable.

(Refer Slide Time: 03:24)

Unilateral (one sided) z-transform

First let us consider, the one sided or unilateral version of the z-transform. The unilateral z-transform of the sequence $\{x_n\}_{n=0}^{\infty}$ is given by the sum

$$Z(x_n) = \sum_{n=0}^{\infty} x_n z^{-n} \quad (1)$$

for all z such that (1) converges. Here z is a complex variable and the set of values of z for which the sum (1) converges, is called the region of convergence (ROC) of the z-transform. The z-transform maps the sequences to functions and their associated region of convergence, such that $Z(x_n)$ is the z-transform of the sequence $\{x_n\}_{n=0}^{\infty}$.

8

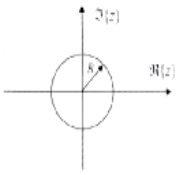

Let us first define a unilateral Z-transform that is one sided Z-transform. So the one sided or unilateral version of the Z-transform is defined as follows. Suppose we have a sequence x_n where n runs from 0 to infinity through the positive integers. So $n=0$ 1 2 3 and so on. So when we are given a sequence x_n .

The unilateral Z-transform of the sequence x_n is defined as $Zx_n = \sum_{n=0}^{\infty} x_n z^{-n}$ for all z such that the summation, the infinite series in 1 converges. Here z is a complex variable and the set of values of z for which the sum converges, is called the region of convergence of the Z-transform. The Z-transform maps the sequence to functions and their associated region of convergence, such that Zx_n is the aztr- of the sequence x_n .

(Refer Slide Time: 04:21)

Unilateral (one sided) z-transform cont...

The sequences for which the z-transform is defined can be real valued, or complex valued. The region of convergence will be all values of z outside of some circle in the complex z-plane of radius R , the "radius of convergence" for the series (1) as shown in the figure below.

9

Now let us consider the sequences for which the Z-transform is defined, the sequences for which the Z-transform is defined can be real valued or complex valued. The region of convergence will be all values of z outside of some circle in the complex z plane of radius R , the radius of convergence for the series 1 as shown in the figure below. So the radius of convergence will be the some region outside the circle of convergence of radius R with center at the origin where R is given as the radius of convergence.

So here for example the region of convergence is the shaded portion and it is outside the circle with center at origin and radius R in the complex z plane. So this region can be represented by $|z| > R$.

(Refer Slide Time: 05:18)

Unilateral (one sided) z-transform cont...

The uniqueness of the z-transform derives from properties of power series expansions of complex functions of complex variables.

Example 1

Consider the sequence $\{x_n\}_{n=0}^{\infty} = 2^n$, defined for non negative n as shown in figure.

Now the uniqueness of the Z-transform derives from properties of power series expansions of complex functions of complex variables. Let us consider the sequence $x_n = 2^n$ where n begins from 0 to infinity. So then consider this sequence which is defined for non-negative integers $n=0, 1, 2, 3$ and so on. So here you can see in this figure, these are the values of n . When $n=1$, $x_1=2$, so we have this point 2.

Then at $n=0$, we have 2 to the power 0, so 1 and we have for $n=1$, we have 2. $n=2$, we have 2 square that is 4. $n=3$, we have 2 cube that is 8 and $n=4$, that is, here, 2 to the power 4 which is 16. $n=0$, you can see it is 1 here. Then let us find the Z-transform of this sequence.

(Refer Slide Time: 06:21)

Example cont...

This discrete time sequence has a z-transform given by

$$Z(2^n) = \sum_{n=0}^{\infty} 2^n z^{-n}$$

or

$$Z(2^n) = \sum_{n=0}^{\infty} \left(\frac{2}{z}\right)^n = \frac{1}{1 - \frac{2}{z}} = \frac{z}{z-2}, \quad |z| > 2$$

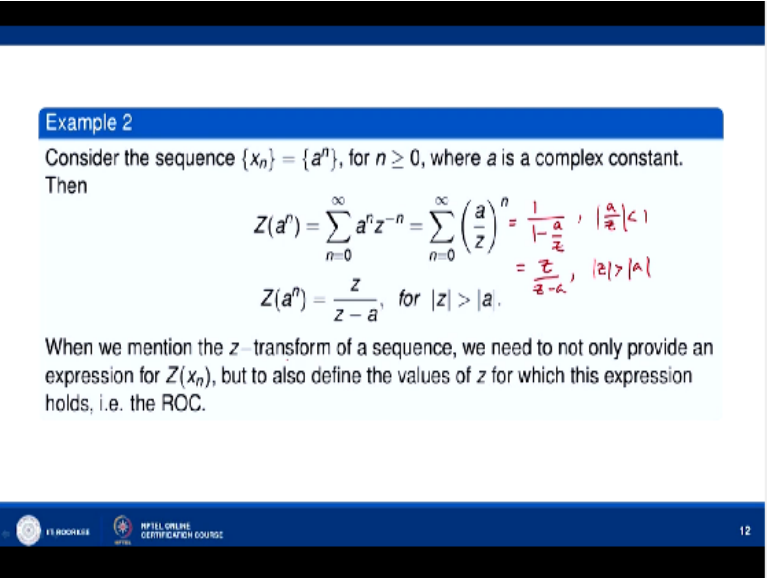

that is the ROC of $Z(x_n)$ is $|z| > 2$. In general, $Z(x_n)$ converges for all z that are large enough, that is, when z is sufficiently large, that the signal $x_n z^{-n}$ becomes summable.

So the discrete time sequence has a Z-transform given by Z of 2 to the power $n = \sum_{n=0}^{\infty} 2^n z^{-n}$. We can also write this as Z of 2 to the power $n = \sum_{n=0}^{\infty} (2/z)^n$. Now this is a geometric series and so its sum will be $1/(1-2/z)$ provided $\text{mod of } 2/z < 1$. So $\text{mod of } 2/z < 1$ gives you $\text{mod of } z > 2$. So the sum of this series is $z/(z-2)$ provided $\text{mod of } z > 2$.

So $\text{mod of } z > 2$ is the region of convergence of this series and you can draw this region of convergence. So this is your circle with center at origin and radius 2. So this is $\text{mod of } z = 2$. Then the region of convergence is this. So for this series, region of convergence is $\text{mod of } z > 2$. Now in general, $Z\{x_n\} = \sum_{n=0}^{\infty} x_n z^{-n}$. So in general, $Z\{x_n\}$ converges for all z that are large enough. That is when z is sufficiently large that the signal $x_n z^{-n}$ becomes summable.

(Refer Slide Time: 07:00)

Example 2

Consider the sequence $\{x_n\} = \{a^n\}$, for $n \geq 0$, where a is a complex constant. Then

$$Z(a^n) = \sum_{n=0}^{\infty} a^n z^{-n} = \sum_{n=0}^{\infty} \left(\frac{a}{z}\right)^n = \frac{1}{1 - \frac{a}{z}}, \quad \left|\frac{a}{z}\right| < 1$$

$$Z(a^n) = \frac{z}{z-a}, \quad \text{for } |z| > |a|.$$

When we mention the z -transform of a sequence, we need to not only provide an expression for $Z(x_n)$, but to also define the values of z for which this expression holds, i.e. the ROC.

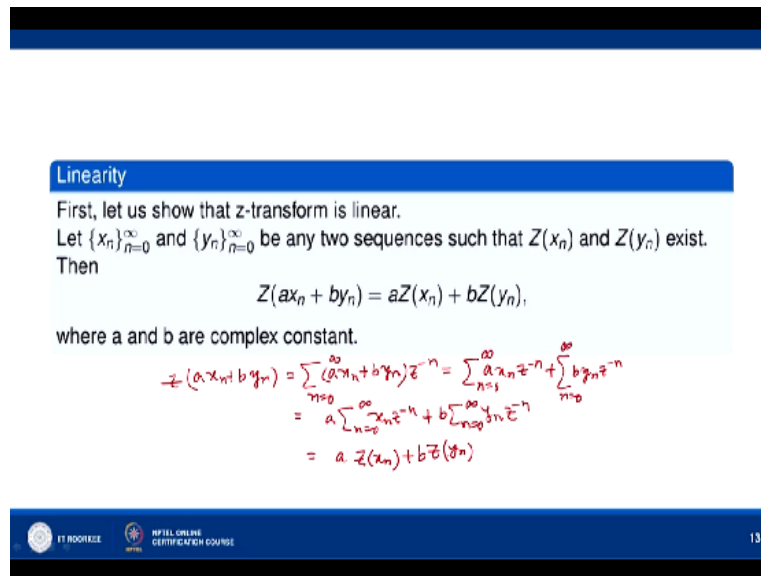

12

Now consider the sequence $x_n = a^n$ to the power n where n greater than or equal to 0 and a is any complex constant here. So Z of a^n to the power n will be $\sum_{n=0}^{\infty} a^n z^{-n}$ and this can be written as $\sum_{n=0}^{\infty} (a/z)^n$. Now again this is a geometric series. So its sum is $1/(1-a/z)$ provided $\text{mod of } a/z < 1$.

So this can be written as $z/(z-a)$ provided $\text{mod of } z > \text{mod of } a$. So the sequence a^n has Z-transform

given by $z/z-a$ where $\text{mod of } z > \text{mod of } a$. Now we mentioned that the Z-transform of a sequence whenever we mentioned the Z-transform of a sequence, we should also write the region of convergence of the series. So not only the expression of Zx_n is to be given, its region of convergence must also be specified. Now let us show that Z-transform is linear, okay.

(Refer Slide Time: 09:05)

Linearity

First, let us show that z-transform is linear.

Let $\{x_n\}_{n=0}^{\infty}$ and $\{y_n\}_{n=0}^{\infty}$ be any two sequences such that $Z(x_n)$ and $Z(y_n)$ exist.

Then

$$Z(ax_n + by_n) = aZ(x_n) + bZ(y_n),$$

where a and b are complex constant.

$$\begin{aligned} Z(ax_n + by_n) &= \sum_{n=0}^{\infty} (ax_n + by_n)z^{-n} = \sum_{n=0}^{\infty} ax_n z^{-n} + \sum_{n=0}^{\infty} by_n z^{-n} \\ &= a \sum_{n=0}^{\infty} x_n z^{-n} + b \sum_{n=0}^{\infty} y_n z^{-n} \\ &= aZ(x_n) + bZ(y_n) \end{aligned}$$

So let x_n and y_n be any 2 sequences such that their Z-transforms exist, then z of $ax_n + by_n$ is given by, by definition, let us write it as $\sum_{n=0}^{\infty} ax_n + by_n \cdot Z$ to the power $-n$ and this can be written as then $\sum_{n=0}^{\infty} ax_n Z$ to the power $-n$ + summation $\sum_{n=0}^{\infty} by_n Z$ to the power $-n$. Now $\sum_{n=0}^{\infty} x_n Z$ to the power $-n$ is convergent. So this is equal to $a \cdot \sum_{n=0}^{\infty} x_n Z$ to the power $-n$ and we have $b \cdot \sum_{n=0}^{\infty} y_n Z$ to the power $-n$.

So since $\sum_{n=0}^{\infty} x_n Z$ to the power $-n$ and $\sum_{n=0}^{\infty} y_n Z$ to the power $-n$ are convergent, okay, we can write this sum, infinite sum as sum of these 2 series and then we can bring this colour a and b outside. So then this is $a \cdot Z$ of $x_n + b \cdot Z$ of y_n . So we have 2 sequences, x_n and y_n whose Z-transforms are known and a and b are any complex constant, then Z-transform of $ax_n + by_n$ will be $a \cdot Zx_n + b \cdot Zy_n$. So that we can obtain. It shows that Z-transform is a linear operation.

(Refer Slide Time: 10:59)

Example 3

Let $x_n = n^p$, $n \in \mathbb{N}$, $p \in \mathbb{N}$ then

$$Z(n^{p+1}) = -z \frac{d}{dz} \{Z(n^p)\}$$

which is the recurrence relation. Hence

$$Z(n) = \frac{z}{(z-1)^2}$$

$$\begin{aligned} Z(n) &= -z \frac{d}{dz} \left\{ \frac{1}{z-1} \right\} \\ \text{and } &= -z \left(-\frac{1}{(z-1)^2} \right) \\ &= \frac{z}{(z-1)^2} \end{aligned}$$

$$Z(n^2) = \frac{z^2 + z}{(z-1)^3} = -z \frac{d}{dz} \left(\frac{z}{(z-1)^2} \right)$$

$$\begin{aligned} z(n^k) &= \sum_{n=0}^{\infty} n^k z^{-n} \\ \frac{d}{dz} z(n^k) &= \sum_{n=0}^{\infty} n^k (-n) z^{-n-1} \\ -z \frac{d}{dz} z(n^k) &= \sum_{n=0}^{\infty} n^{k+1} z^{-n} \\ &= z(n^{k+1}) \\ z(n) &= -z \frac{d}{dz} z(1) \\ &= -z \frac{d}{dz} \left(\frac{z}{z-1} \right) \end{aligned}$$

Now let us consider a sequence $x_n = n^p$ where n is there in \mathbb{N} and p belongs to \mathbb{N} . So Z of n to the power $p = \sum_{n=0}^{\infty} n^p z^{-n}$, okay. Now let us differentiate z of n to the power p . So then what we get? Summation $n=0$ to infinity n to the power $p \cdot z$ to the power $-n-1$. Let us multiply both sides by $-z$, then $-z \frac{d}{dz}$ of z n to the power $p = \sum_{n=0}^{\infty} n^{p+1} z^{-n}$, okay.

Now right side is Z -transform of n to the power $p+1$. So Z -transform of n to the power $p+1$ is given by $-z \frac{d}{dz}$ of Z -transform of n to the power p . And this relation is called as the recurrence relation, okay. If you know the Z -transform of n to the power p , you can find Z -transform of n to the power $p+1$. By differentiating z of n to the power p with respect to z and then multiplying by $-z$.

For example, let us find the Z -transform of n , okay. Z -transform of n , you can take $p=1$, if you take p , we have taken p as 1, okay. So Z -transform of n if we want to know, we Z -transform of n square we can find here. If we take $p=0$, even for $p=0$ it is true because Z -transform of n we can find here. So if you take $p=0$ here, we get z of $-z \frac{d}{dz}$ of Z -transform of, p is 0, so we get 1, okay. Now Z -transform of n to the power n we have found.

Z -transform of a to the power n where a is any complex number. We can take a as 1, okay. Then 1 to the power n will be 1 for all n . So we will have the sequence x_n as 1 for all n , okay. And that

sequence we can consider. So then that gives you Z-transform of $1/z-1$, where $\text{mod of } z > 1$. So this is equal to $-z d/dz$ of $1/z-1$ provided $\text{mod of } z > 1$. So then we can differentiate this. We can write it as $Zn = -z d/dz$ of $1/z-1$, we can write it as $1+1/z-1$.

So then $1/z-1$ can be written as $1+1/z-1$, we can differentiate this. This is $-z$ and then we get $-1/z-1$ whole square. So what we get is $1/z-1$ whole square, okay. So we get Z-transform of n . Z-transform of n is $1/z-1$ whole square. Now we know the Z-transform of n . We can find the Z-transform of n square. So Z-transform of n square will be equal to $-z * d/dz$ of $1/z-1$ whole square. So when you differentiate $1/z-1$ whole square with respect to z and multiply by $-z$, we get the Z-transform of n square which is $1/z-1$ whole cube.

(Refer Slide Time: 15:20)

Damping rule

If $Z(x_n) = X(z)$ then $Z(a^{-n}x_n) = X(az)$.

Corollary: $Z(a^n x_n) = X\left(\frac{z}{a}\right)$ ✓

The geometric factor a^{-n} when $|a| < 1$, damps the function x_n , hence the name damping rule.

Applying the damping rule, we have

we know
 $Z(n) = \frac{z}{(z-1)^2} = X(z)$
 $Z(na^n) = \frac{(za)^n}{\left(\frac{z}{a}-1\right)^2} = \frac{(za)^n}{(z-a)^2}$
 and $Z(n^2 a^n) = \frac{az^2 + a^2 z}{(z-a)^3}$

Any definition
 $Z(x_n) = X(z) = \sum_{n=0}^{\infty} x_n z^{-n}$
 then $Z(a^n x_n) = \sum_{n=0}^{\infty} a^n x_n z^{-n}$
 $= \sum_{n=0}^{\infty} x_n (az)^{-n} = X(az)$
replacing a by 1/a in the above result we get
 $Z(a^n x_n) = X\left(\frac{z}{a}\right)$
 $Z(n^n) = \frac{z^3+z}{(z-1)^3} \Rightarrow Z(n^2 a^n)$

FT INSTITUTE
 NPTEL ONLINE
 CERTIFICATION COURSE

15

Now let us discuss a property of Z-transform, another property. if Z of $x_n = Xz$, then Z of a to the power $-n$ $x_n = Xaz$. And a corollary to this result is Z of a to the power $n * x_n$ is X of z/a . So let us first show that if Z of x_n is Xz , then Z of a to the power $-n * x_n$ is Xaz . So by definition, Z of $x_n = Xz = \sum_{n=0}^{\infty} x_n z$ to the power $-n$. Now let us multiply x_n by a to the power $-n$. So then Z-transform of a to the power $-n * x_n$ will be equal to limit $\sum_{n=0}^{\infty} a$ to the power $-n x_n * z$ to the power $-n$.

Now this right hand side can be written as $\sum_{n=0}^{\infty} x_n az$ to the power $-n$. And therefore, by our definition, this is X of az , okay. So Z-transform of a to the power $-n$ $x_n = X$ of

okay. Now here if you replace $1/a$ by a , then you get the corollary, okay. So replacing a by $1/a$ in the above result, we get Z-transform of a^n to the power n is X_z of z/a . So we get this corollary, okay.

Now the geometric factor a to the power $-n$, when $|a| < 1$, damps the function x_n and that is why we call it as a damping rule. So now if you use the damping rule, we can determine the Z-transform of the sequence $n \cdot a^n$, okay. Because we know the Z-transform of n . So recall that Z-transform of n is given by $z/(z-1)^2$, okay. We know Z-transform of $n \cdot z/(z-1)^2$ is $z/(z-1)^2$. So this is your X_z , okay. Sequence X_n is n , okay. Now we want Z-transform of $n \cdot a^n$ to the power n . So Z-transform of $n \cdot a^n$ to the power n . We can apply the corollary, okay.

So Z-transform of $X_n \cdot a^n$ to the power n is $X_{z/a}$. So replace z by z/a in the expression for X_z . So we get $z/a / (z/a - 1)^2$, okay. So this is $z/a / (z-a)^2 / a^2$. So this a^2 comes here and what we get? $az / (z-a)^2$, okay. So Z-transform of $n \cdot a^n$ to the power n is $az / (z-a)^2$. Similarly, Z-transform of $n^2 \cdot a^n$ to the power n can be determined because we now know the Z-transform of $n \cdot a^n$ to the power n , okay.

So we know the Z-transform or we can apply, we know the Z-transform of n^2 , okay. We have to use that. Z-transform of n^2 is $z^2 / (z-1)^3$. Now we want the Z-transform of $n^2 \cdot a^n$ to the power n . So we can apply the damping rule. So let us recall that Z-transform of n^2 is $z^2 / (z-1)^3$. So this gives you Z-transform of $n^2 \cdot a^n$ to the power n , replace z by z/a , okay.

(Refer Slide Time: 20:16)

$$\begin{aligned}
 Z(n^2 a^n) &= \frac{\left(\frac{z}{a}\right)^2 + \left(\frac{z}{a}\right)}{\left(\frac{z}{a} - 1\right)^3} \\
 &= \frac{\frac{z^2 + az}{a^3}}{\left(\frac{z-a}{a}\right)^3} = \frac{az^2 + a^2 z}{(z-a)^3}
 \end{aligned}$$

$u_n = 1, \forall n \geq 0$
 $n+k = j$
 $n = j-k$

$$\begin{aligned}
 Z(y_{n+k} u_n) &= \sum_{n=0}^{\infty} y_{n+k} u_n z^{-n} \\
 &= \sum_{n=0}^{\infty} y_{n+k} z^{-n} \\
 &= z^k \sum_{j=k}^{\infty} y_j z^{-(j-k)} \\
 &= z^k \left[\sum_{j=k}^{\infty} y_j z^{-j} - \sum_{j=0}^{k-1} y_j z^{-j} \right]
 \end{aligned}$$

$Z(y_{n+k} u_n) = z^k \left[y(z) - y_0 - \frac{y_1}{z} - \frac{y_2}{z^2} - \dots - \frac{y_{k-1}}{z^{k-1}} \right]$

So we can write that Z-transform of $n^2 a^n$ is $\frac{az^2 + a^2 z}{(z-a)^3}$. So this will give you $\frac{z^2 + az}{z^3 - 3az^2 + 3a^2 z - a^3}$. This is $\frac{z^2 + az}{z^3 - 3az^2 + 3a^2 z - a^3}$ and here we get $\frac{z^2 + az}{(z-a)^3}$. So we get $\frac{az^2 + a^2 z}{(z-a)^3}$. So Z-transform of $n^2 a^n$ is $\frac{az^2 + a^2 z}{(z-a)^3}$.

(Refer Slide Time: 21:18)

Example 4

We can use linearity of the z-transform to compute the z-transform of trigonometric functions, such as $x_n = \cos(\omega n)$, for $n \geq 0$.

$$\begin{aligned}
 Z(\cos(\omega n)) &= \sum_{n=0}^{\infty} \cos(\omega n) z^{-n} \\
 &= \sum_{n=0}^{\infty} \frac{1}{2} (e^{j\omega n} + e^{-j\omega n}) z^{-n} \\
 &= \frac{1}{2} \sum_{n=0}^{\infty} (e^{j\omega})^n z^{-n} + \frac{1}{2} \sum_{n=0}^{\infty} (e^{-j\omega})^n z^{-n} \\
 &= \frac{1}{2} \frac{z}{z - e^{j\omega}} + \frac{1}{2} \frac{z}{z - e^{-j\omega}}, \quad |z| > 1
 \end{aligned}$$

$\frac{1}{2} \left[\frac{z}{z - e^{j\omega}} + \frac{z}{z - e^{-j\omega}} \right]$
 $= \frac{1}{2} \frac{z(z - e^{-j\omega}) + z(z - e^{j\omega})}{(z - e^{j\omega})(z - e^{-j\omega})}$
 $= \frac{1}{2} \frac{2z^2 - 2z \cos \omega}{z^2 - 2z \cos \omega + 1}, \quad |z| > 1$

$Z(a^n) = \frac{z}{z-a}, \quad |z| > |a|$
 Taking $a = e^{j\omega}$
 $\frac{1}{2} \frac{z}{z - e^{j\omega}}, \quad |z| > 1$
 $\frac{1}{2} \frac{z}{z - e^{-j\omega}}, \quad |z| > 1$

$\frac{z^2 - z \cos(\omega)}{z^2 - 2z \cos(\omega) + 1}, \quad |z| > 1$

Now we can find the Z-transform of sequence which is of trigonometric functions. Let us say $x_n = \cos \omega n$ where n greater than or equal to 0. So for this, we can use the linearity of the Z-transform, okay. Linearity of the Z-transform can be used to determine the Z-transform of $x_n = \cos \omega n$. So Z of $\cos \omega n$ is, by definition, $\sum_{n=0}^{\infty} \cos \omega n z^{-n}$.

Now we know that $\cos z = \frac{e^{iz} + e^{-iz}}{2}$, okay. So we have $\sum_{n=0}^{\infty} \frac{1}{2} e^{i\omega n} z^n + \frac{1}{2} e^{-i\omega n} z^{-n}$. We put the value of $\cos \omega n$ here. So $e^{i\omega n} z^n + e^{-i\omega n} z^{-n}$. Now $e^{i\omega n}$ can be written as $e^{i\omega}$ to the power n and we are using linearity here, okay.

So using linearity, this half comes out and we write $\sum_{n=0}^{\infty} e^{i\omega n} z^n + \sum_{n=0}^{\infty} e^{-i\omega n} z^{-n}$. $e^{i\omega n}$ is further $e^{i\omega}$ to the power n and then we have $\sum_{n=0}^{\infty} e^{i\omega n} z^n + \sum_{n=0}^{\infty} e^{-i\omega n} z^{-n}$. Now this ω is a real quantity, okay. This ω is real quantity. So what we have?

Let us recall that Z-transform of a^n is $\frac{z}{z-a}$, okay. Z-transform of a^n is $\frac{z}{z-a}$ where $|z| > |a|$, okay. So taking $a = e^{i\omega}$, okay. Taking $a = e^{i\omega}$ to the power n because a here could be a complex number. So we get the Z-transform of the first summation, Z-transform of this will be $\frac{1}{2} \frac{z}{z - e^{i\omega}}$, where $|z| > |e^{i\omega}|$ to the power n which is 1, okay.

So $|z| > 1$. And second term will be? $\frac{1}{2}$, similarly we now take $e^{-i\omega}$ and $|e^{-i\omega}|$ to the power n when ω is real, is equal to 1. So again when $|z| > 1$, Z-transform here will be $\frac{1}{2}$. This will be $\frac{1}{2} \frac{z}{z - e^{-i\omega}}$ to the power n , okay. So what we get is this. $\frac{1}{2} \frac{z}{z - e^{i\omega}} + \frac{1}{2} \frac{z}{z - e^{-i\omega}}$. And this is $\frac{1}{2} \frac{z}{z - e^{i\omega}} + \frac{1}{2} \frac{z}{z - e^{-i\omega}}$.

Here we have $\frac{z^2 - e^{i\omega}}{z^2 - e^{i\omega}}$ to the power n , okay. $\frac{z^2 - e^{i\omega}}{z^2 - e^{i\omega}}$, and then we have, this is equal to $\frac{1}{2} \frac{2z^2}{z^2 - e^{i\omega}}$, this will be $\frac{2z^2}{z^2 - e^{i\omega}}$, so $\frac{2z^2}{z^2 - e^{i\omega}}$ to the power n to the power n to the power n is $2\cos \omega$; here in the denominator, we will have $\frac{z^2 - e^{i\omega}}{z^2 - e^{i\omega}}$ to the power n to the power n . So $-2\cos \omega$ and then we have $\frac{2z^2}{z^2 - e^{i\omega}}$ to the power n to the power n which is $e^{i\omega}$ to the power 0, so that is 1.

So this 2 will cancel with this 2 and we will have $z^2 - z \cos \omega / z^2 - 2z \cos \omega + 1$. Now this series converges when $\text{mod of } z > \text{mod of } e$ to the power $i \omega$. So $\text{mod of } z > 1$. And this series converges when $\text{mod of } z > \text{mod of } e$ to the power $-i \omega$, which is also 1, okay. So here also $\text{mod of } z > \text{mod of } e$ to the power $-i \omega$ which is equal to 1. So for both the series, okay, the region of convergence is the same, $\text{mod of } z > 1$, okay. So this is equal to Z-transform of $\cos \omega n$ where $\text{mod of } z > 1$, okay.

(Refer Slide Time: 26:27)

Example cont...

Let us now find the z-transform for $x_n = \sin(\omega n)$.

$$x_n = \frac{1}{2i}(e^{i\omega n} - e^{-i\omega n})$$

$$= \frac{1}{2i}(e^{i\omega})^n - \frac{1}{2i}(e^{-i\omega})^n$$

Hence

$$Z(\sin(\omega n)) = \frac{z \sin(\omega)}{z^2 - 2z \cos(\omega) + 1}, |z| > 1$$

Handwritten notes on the slide show the derivation of the Z-transform for $\sin(\omega n)$ using the identity $\sin(\omega n) = \frac{1}{2i}(e^{i\omega n} - e^{-i\omega n})$. The Z-transform is then calculated as $Z(\sin(\omega n)) = \frac{1}{2i} \left(\frac{z}{z - e^{i\omega}} - \frac{z}{z - e^{-i\omega}} \right)$. The region of convergence is noted as $|z| > 1$.

Now let us similarly, we can find the Z-transform of the sequence $\sin \omega n$ when $x_n = \sin \omega n$. So x_n is $1/2i e$ to the power $i \omega n$ - e to the power $-i \omega n$. And we can write as in the case of the $\cos \omega n$, we can write it as $1/2i e$ to the power $i \omega n$ raise to the power n and $-1/2i e$ to the power $-i \omega n$ raise to the power n .

Then Z of $\sin \omega n$ will be equal to $1/2i$, using linearity, Z-transform of e to the power $i \omega n$ - $1/2i \omega e$ raise to the power n and Z-transform of e to the power $-i \omega n$ raise to the power n , okay. So this is $1/2i z/z - e$ to the power $i \omega n$ - $z/z - e$ to the power $-i \omega n$. Again, we are applying here the formula z of a to the power n . So this series, the Z-transform of a to the power n is $z/z - a$ when $\text{mod of } z > \text{mod of } a$.

So $\text{mod of } z$ for the convergence of this, we have $\text{mod of } z > \text{mod of } e$ to the power $i \omega$ which is equal to 1. And for the convergence of the series here, okay, the region of convergence is mod

of $z > \text{mod of } e$ to the power $-i \omega$. So this is equal to also 1, okay. So region of convergence is again same for both the series, the series that occurs here and the series that occurs here.

So then this is $1/2i$, we can write $z \cdot e^{i \omega} \cdot z \cdot e^{-i \omega}$, that is $z^2 - 2z \cos \omega$ as in the pre-case of $\cos \omega n$ we have seen, $+1$ and here we will get z^2 and here $-z^2$, that will cancel. So here we will get $-ze$ to the power $i \omega$. Here $+ze$ to the power $i \omega$. So $z^* e$ to the power $i \omega - e$ to the power $-i \omega$, okay. Now z of e to the power $i \omega$, $z^* e$ to the power $i \omega - e$ to the power $-i \omega / 2i$ is $\sin \omega$, okay. So we get $z \sin \omega / z^2 + 1$, okay. And this region of convergence is $\text{mod } z > 1$.

(Refer Slide Time: 29:05)

From the definition of the z-transform, the discrete time impulse defined by,

$$\delta_n = \begin{cases} 1, & n = 0 \\ 0, & \text{otherwise,} \end{cases}$$

has a z-transform

$$\delta_n \leftrightarrow 1$$

Another sequence for which we can apply knowledge of an existing transform is the unit step, u_n , where

$$u_n = \begin{cases} 1, & n \geq 0 \\ 0, & n < 0 \end{cases}$$

Then

$$u_n \leftrightarrow \frac{z}{z-1}, |z| > 1.$$

Handwritten notes on the slide include:

- $Z(\delta_n) = \sum_{n=0}^{\infty} \delta_n z^{-n} = 1$
- $u_n = 1, \forall n \geq 0$
- $= 0, n < 0$
- $Z(a^n) = \frac{z}{z-a}, |z| > |a|$
- Let us take $a=1$
- $Z(1) = \frac{z}{z-1}, |z| > 1$

At the bottom of the slide, there is a footer with the text "PT ROORKEE" and "NPTEL ONLINE CERTIFICATION COURSE" along with a logo and the number "19".

Now let us take the discrete time impulse δ_n , okay. δ_n is defined as 1 when $n=0$ and 0 otherwise. So unilateral Z-transform here will be what? Z-transform of δ_n , okay will be equal to $\sum_{n=0}^{\infty} \delta_n z^{-n}$. Now at $n=0$, $\delta_n=1$. So when you put $n=0$ here, we get δ_0 which is 1 z to the power 0 is also 1, so we get 1. And $\delta_n=0$ for all values of n other than 0.

So $\delta_n=0$ makes other terms 0. And therefore, Z-transform of $\delta_n=1$. So δ_n goes to 1 and 1 goes to δ_n , the inverse Z-transform of 1 will be equal to δ_n , okay. So Z-transform of δ_n is 1 and inverse Z-transform of 1 is δ_n . Now another sequence for which we can apply the knowledge of an existing transform is the unit step function. Z-transform of u_n . $u_n=1$

for all n greater than or equal to 0, okay and 0 when $n < 0$.

So we can apply the formula that we have already found for a to the power n sequence. We have seen that Z-transform of a to the power $n = z/z-a$ when $\text{mod of } z > \text{mod of } a$, okay. Here a is any complex constant. So let us take $a=1$, okay. So Z-transform of 1 to the power n . 1 to the power n is 1, so $1 = z/z-1$, okay, when $\text{mod of } z > 1$, okay. So here the sequence $u_n = a$ to the power n where $a=1$ for all n greater than or equal to 0.

Because other terms of the sequence are all 0. So sigma, if you find the Z-transform of u_n , it is equal to sigma $n=0$ to infinity $1 \times n$ is 1 or you can say u_n is $1 \times z$ to the power $-n$, okay. So this is same as Z-transform of the sequence 1. So Z-transform of the unit step function is $z/z-1$ where $\text{mod of } z > 1$.

(Refer Slide Time: 31:40)

Delay Property
When a sequence is delayed by a positive amount, then we have that

$$Z(y_{n-k} u_{n-k}) = z^{-k} Y(z), \text{ where } k \in \mathbb{N}.$$

Advance Property

$$Z(y_{n+k} u_n) = z^k \left(Y(z) - \sum_{m=0}^{k-1} y_m z^{-m} \right), \text{ where } k \in \mathbb{N}.$$

Handwritten derivations on the slide include:

$$Z(y_{n-k} u_{n-k}) = \sum_{n=-\infty}^{\infty} y_{n-k} u_{n-k} z^{-n} = \sum_{n=-\infty}^{\infty} y_n u_n z^{-(n+k)} = z^{-k} \sum_{n=-\infty}^{\infty} y_n u_n z^{-n} = z^{-k} Y(z)$$

$$Z(y_{n+k} u_n) = \sum_{n=-\infty}^{\infty} y_{n+k} u_n z^{-n} = \sum_{n=-\infty}^{\infty} y_n u_n z^{-(n-k)} = \sum_{n=-\infty}^{\infty} y_n u_n z^{-n} z^k = z^k \sum_{n=-\infty}^{\infty} y_n u_n z^{-n} = z^k Y(z)$$

$$Z(y_{n+1} u_n) = z^1 (Y(z) - y_0 z^{-0}) = z(Y(z) - y_0)$$

Now let us consider the delay property. When a sequence is delayed by a positive amount, then we have Z of $y_{n-k} u_{n-k} = z$ to the power $-k$ Yz . Here k is any natural number. Now this we can easily see Z-transform of, where we have y_{n-k} sequence, $y_{n-k} u_{n-k}$, this equal to sigma $n=0$ to infinity $y_{n-k} u_{n-k}$, okay. When $n=0$ 1 2 and so on, then u_{n-k} is 0 whenever n is negative, okay. u_n is we have seen, u_n is equal to 0, okay when n is negative.

So here, this summation will be reduced to sigma $n=k$ to infinity because if $n < k$, $n-k < 0$, so u_{n-k}

is 0. So $y_{n-k} u_{n-k}$. And u_{n-k} now is equal to 1. So we get here, and we also have z to the power $-n$ here. So $1 \cdot z$ to the power $-n$ we have. Now replace $n-k$ by equal to j , okay. So when you do that, this is $\sum_{j=0}^{\infty} y_j$, and $n=k+j$, so z to the power $-k+j$. So we can write this as z to the power $-k$ we can write outside the summation and $\sum_{j=0}^{\infty} y_j$ and we have z to the power $-j$.

So this is z to the power $-k$ * Z-transform of y_n sequence, okay. So which is Yz . So z to the power $-k$ * Yz , okay. So we get this formula. This is the delay property of the Z-transform. Now advance property, okay. When y_n is advanced by an amount k . So Z of $y_{n+k} u_n$ we want to find, okay. So Z-transform of $y_{n+k} u_n$, we want to find this, okay. So this is $\sum_{n=0}^{\infty} y_{n+k} z^{-n}$ to the power $-n$, okay.

Replacing this we can write. So this is when n takes values from 0, this is what? $u_n=1$, okay. $u_n=1$ for all n greater than or equal to 0, okay. So we get here $\sum_{n=0}^{\infty} y_{n+k} z^{-n}$ to the power $-n$, okay. Now $n+k$ if I write as j , then what will happen? j will begin with $n=0$, okay. So j will begin with k and go up to infinity and here we shall have $y_j z^{-n}$ to the power $n=k-j$, so $-k-j$, okay.

So we shall write it as z to the power $-k$ * $\sum_{j=k}^{\infty} y_j z^{-j}$ or it is $j-k$, okay. $n=j-k$, z to the power k $\sum_{j=k}^{\infty} y_j z^{-j}$ to the power $-j$. Now I can write it as z to the power k * $\sum_{j=0}^{\infty} y_j z^{-j}$ to the power $-j$, when I subtract the terms from $j=0$ to $k-1$, $y_j z^{-j}$ to the power j , okay. So this means that Z-transform of $y_{n+k} u_n = z$ to the power k and I replace this, this is Z-transform of y_j sequence, okay.

Z-transform of y_n sequence it is, so I write it as yz , okay. Then we have here $yz - y_0 - y_1/z - y_2/z^2$ and so on, $-y_{k-1}/z$ to the power $k-1$. So this is the advanced property. Z-transform of $y_{n+k} u_n$ is z to the power k * $yz - y_0 - y_1/z - y_2/z^2$ and so on, $y_{k-1} z$ to the power $k-1$. So this is what we get, okay.

(Refer Slide Time: 37:00)

Convolution

One of the useful properties of the z-transform is that, it maps convolution in the time domain into multiplication in the z-transform domain.

Let us assume that $x_n = h_n = 0$, $n < 0$. The convolution of the sequences h_n and x_n is defined as

$$y_n = \sum_{m=-\infty}^{\infty} h_m x_{n-m} = \sum_{m=0}^{\infty} h_m x_{n-m} = \sum_{m=0}^n h_m x_{n-m}$$

MIT

NPTEL ONLINE
CERTIFICATION COURSE

20

Now let us go to convolution property. So one of the useful properties of the Z-transform is that, it maps convolution in the time domain into multiplication in the time domain. If you have 2 sequences x_n and h_n which are defined as 0, when $n < 0$, then the convolution of the sequences h_n and x_n is defined as $y_n =$.

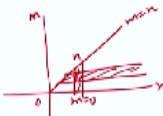

Convolution of h_n and y_n gives another sequence which is given by y_n , $y_n = \sum_{m=-\infty}^{\infty} h_m x_{n-m}$. Now in this case $x_n = 0$ when n is negative and $h_n = 0$ when n is negative. So here h_m will be 0 as long as m is negative. So this m will vary from 0 to infinity. $h_m x_{n-m}$, because of h_m , okay, sum will be 0, I mean terms will be 0 here so long as m is taking negative values.

Now x_{n-m} , okay, will be 0 whenever $n < m$, okay. So this means that $m > n$, okay. So this means that this is equal to $\sum_{m=0}^n h_m x_{n-m}$, okay. So if you assume that x_n and h_n are 0's for $n < 0$, negative integer values of n , then $y_n = \sum_{m=0}^n h_m x_{n-m}$ because if m is more than n , okay, then $n-m$ is negative, so x_{n-m} is 0, okay.

(Refer Slide Time: 38:49)

Convolution Cont...

Taking z-transform on both sides, we have

$$\begin{aligned}
 Z(y_n) &= \sum_{n=0}^{\infty} y_n z^{-n} \quad \left(y_n = \sum_{m=0}^n h_m x_{n-m} \right) \\
 &= \sum_{n=0}^{\infty} \left(\sum_{m=0}^n h_m x_{n-m} \right) z^{-n} = \sum_{m=0}^{\infty} \sum_{n=m}^{\infty} h_m x_{n-m} z^{-n} \\
 &= Z(x_n) Z(h_n) \quad \left(n-m=j \right) \\
 &= \left(\sum_{m=0}^{\infty} h_m z^{-m} \right) \left(\sum_{j=0}^{\infty} x_j z^{-j} \right) \\
 &= Z(h_n) Z(x_n)
 \end{aligned}$$

So now let us find the Z-transform of y_n . We are going to show that Z-transform of y_n is the product of the Z-transforms of the 2 sequences x_n and h_n , okay. So Z-transform of y_n is $\sum_{n=0}^{\infty} y_n z^{-n}$ and let us now put the value of y_n , okay. So y_n if you put, y_n will be equal to, $\sum_{m=0}^n h_m x_{n-m}$, okay. So this will be $y_n = \sum_{m=0}^n h_m x_{n-m}$, alright.

So we have this, this gives you $\sum_{n=0}^{\infty} \sum_{m=0}^n h_m x_{n-m} z^{-n}$, okay, $h_m x_{n-m} z^{-n}$, okay. So this will be equal to, now let us see m depends on n , right. So this is your $m=n$, okay. m varies from, n is independent variable, n is here and m is here, okay. So m varies from 0 to n , okay. So we are taking this like this and then I change the order of integration. So I put it like this.

So if you do this, then we shall change the order of integration and we will get n varies now from m to infinity, so this is, can we put as n varies from m to infinity, okay. And m varies from 0 to infinity, okay. And we have $h_m x_{n-m} z^{-n}$, okay. This interchanging the order of the summation, we get this. Now put $n-m=j$, okay. So what we will have? $\sum_{m=0}^{\infty} h_m z^{-m}$ and here we shall have $n-m=j$, so j varies from 0 and goes up to infinity, okay.

And we have h_m, x_{n-m} will be x_j and z to the power $-j+m$, right. So this will be equal to $\sum_{m=0}^{\infty} h_m z^{-m} \left(\sum_{j=0}^{\infty} x_j z^{-j} \right)$, right. So this will be equal to $\sum_{m=0}^{\infty} h_m z^{-m}$ and then we have

summation $j=0$ to infinity $x_j z$ to the power $-j$, okay. Now this is Z-transform of h_n , this is Z-transform of x_n , okay. So we get Z-transform of $x_n * Z$ -transform of h_n here, okay. So this is the proof.

So Z-transform, if we know the Z-transforms of 2 sequences x_n and h_n , okay, then the Z-transform of their convolution can be found. It is the product of their Z-transforms. Now this property of Z-transforms is used in the solution of difference equations. Also we use this property in the probability theory. Now let us discuss the initial value problem for casual signal.

(Refer Slide Time: 43:09)

Initial value theorem for casual signal

We have

$$x_0 = \lim_{z \rightarrow \infty} Z(x_n),$$

if the limit exists.

Proof:

$$Z(x_n) = \sum_{n=0}^{\infty} x_n z^{-n}$$

$$= x_0 + x_1 z^{-1} + x_2 z^{-2} + \dots$$

$$\lim_{z \rightarrow \infty} Z(x_n) = x_0$$

$x_n = \{x_0, x_1, x_2, \dots\}$
 $Z(x_n) = \sum_{n=0}^{\infty} x_n z^{-n}$
 $= x_0 + \frac{x_1}{z} + \frac{x_2}{z^2} + \frac{x_3}{z^3} + \dots$
 $\lim_{z \rightarrow \infty} Z(x_n) = x_0$

22

So let us say we want to prove that the initial value, the sequence we know is x_n , the first term of the sequence is x_0 , okay, x_0, x_1, x_2 and so on, okay. So we want to determine the initial value or initial term of the sequence that is x_0 . So the initial value theorem says that the initial value of the sequence x_0 can be found if we take n tends to infinity and Z of x_n , okay. So Z of x_n is what? Z of x_n is $\sum_{n=0}^{\infty} x_n z^{-n}$ to the power $-n$.

So this is $x_0 + x_1/z + x_2/z^2 + \dots$, okay. So limit z tends to infinity $Z x_n$, okay, $= x_0$ because when z goes to infinity, $1/z$ goes to 0. So these terms all will be 0, will tend to 0. So x_1/z , x_2/z^2 , x_3/z^3 , all will tend to 0. So in the Z-transform of x_n , when we take z to go to infinity, we get x_0 . So if the limit of Z of x_n as z tends to infinity exist, then it will give us the value of x_0 , the initial value of the sequence. So this is the proof.

(Refer Slide Time: 44:55)

Final value theorem for z-transform

Theorem: If $Z\{x_n\} = X(z)$ and $\lim_{k \rightarrow \infty} x_k$ exists, then

$$\lim_{k \rightarrow \infty} x_k = \lim_{z \rightarrow 1} (z-1)X(z).$$

Proof: Let's take the z-transform of the quantity $(x_{k+1} - x_k)$. We have

$$\begin{aligned} Z[x_{k+1} - x_k] &= \sum_{k=0}^{\infty} (x_{k+1} - x_k)z^{-k} \\ &= \lim_{k \rightarrow \infty} \left(\sum_{n=0}^k (x_{n+1} - x_n)z^{-n} \right) \\ &= \lim_{k \rightarrow \infty} \left(\sum_{n=0}^k x_{n+1}z^{-n} - \sum_{n=0}^k x_n z^{-n} \right) \end{aligned}$$

Handwritten notes on the slide:

- Left side: $x_k z^{-(k-1)} - x_k z^{-k} = x_k z^{-k}(1-z^{-1})$
- Right side: $x_1 z^0 - x_1 z^{-1} = x_1(1-z^{-1})$, $x_2 z^{-1} - x_2 z^{-2} = x_2 z^{-1}(1-z^{-1})$, $x_{k+1} z^{-k} - x_{k+1} z^{-(k+1)} = x_{k+1} z^{-k}(1-z^{-1})$

23

Let us go to next theorem which is final value theorem for Z-transform. If Z of $x_n = X(z)$ and limit of x_k as k goes to infinity, the final term of the sequence is X infinity. So that is why we call it as final value theorem. So final value X infinity can be found or limit of x_k as k tends to infinity can be found from this formula, limit z tends to 1, $z-1 \cdot X(z)$. Now let us, to prove this result, let us take the Z-transform of the expression $x_{k+1} - x_k$.

So Z-transform of $x_{k+1} - x_k$ is $\sum_{k=0}^{\infty} (x_{k+1} - x_k)z^{-k}$ and this can be written as, now this $x_{k+1} - x_k$ we can write in this form, limit k tends to infinity $\sum_{n=0}^k x_{n+1} - \sum_{n=0}^k x_n z^{-n}$. Now here what is happening; we can now write this finite sum, these are finite sum, so we can write it as $\sum_{n=0}^k x_{n+1} z^{-n} - \sum_{n=0}^k x_n z^{-n}$. So then what we will do?

(Refer Slide Time: 46:12)

Final value theorem for z-transform cont...

$$\begin{aligned}
 &= \lim_{k \rightarrow \infty} \left(-x_0 + x_1(1 - z^{-1}) + \dots + x_l z^{-(l+1)}(1 - z^{-1}) + \dots \right. \\
 &\quad \left. + \underline{x_k z^{-(k+1)}(1 - z^{-1})} + \underline{x_{k+1} z^{-k}} \right) \\
 \lim_{z \rightarrow 1} Z[x_{k+1} - x_k] &= \lim_{z \rightarrow 1} \lim_{k \rightarrow \infty} \left(-x_0 + \dots + x_l z^{-(l+1)}(1 - z^{-1}) + \dots \right. \\
 &\quad \left. + \underline{x_{k+1} z^{-k}} \right) \\
 &= \lim_{k \rightarrow \infty} \lim_{z \rightarrow 1} \left(-x_0 + \dots + x_l z^{-(l+1)}(1 - z^{-1}) + \dots \right. \\
 &\quad \left. + \underline{x_{k+1} z^{-k}} \right) = \lim_{k \rightarrow \infty} (-x_0 + x_{k+1})
 \end{aligned}$$

So we can write down this further as limit k goes to infinity, okay, and you put the values of n and first term will be $-x_0$, okay. Here you will get when you put $n=0$, you get $-x_0$. When you put $n=0$ here, what you get? $x_1 z$ to the power $-n$ and here when you put $n=1$, what you get? $-x_1$. Here when you put $n=0$, you get $x_1 z$ to the power 0 , okay. When you put $n=0$ here, we get $x_1 z$ to the power 0 .

Here you get $-x_1 z$ to the power -1 . So this is equal to $x_1 * 1 - z$ to the power -1 . Similarly, we can put $n=1$ here. You get $x_2 z$ to the power -1 and you will get here $n=2$, if you put, you get $x_2 z$ to the power -2 , okay. So this way we will get these terms. So at $-x_0$, $x_1 1 - z$ to the power -1 , then the next term will be $x_2 z$ to the power -1 $1 - z$ to the power -1 , okay like this. So if we go like this, here what will happen?

$x_1 * z$ to the power $-1-1$, okay. So like we had here, $x_2 z$ to the power -1 , okay. So when you put here 1 , okay, $x_1 z$ to the power, we will have $-1-1$. So we will get this one, $x_1 z$ to the power $-1-1$ when $-z$ to the power -1 and then the term, last term is this one. Last term is x_{n+1} . So last term will be $x_{k+1} z$ to the power $-k$ and here what we will get? $x_k z$ to the power $-k$, you get $x_{k+1} z$ to the power $-k$ and here you get $-x_k$, just a minute, $x_{k+1} z$ to the power $-k$, that is the last term, okay.

And the term before that is, when you put $n=k-1$, so $x_k z$ to the power $-k-1$, okay and here what

we will get? $-x_k z$ to the power $-k$. So $x_k z$ to the power $-k+1$ z to the power -1 we get. Here when we put here $n=k-1$, so we got this, okay. And $n=k$ here gives you this, okay. So z to the power $-k-1$ we write, okay. So $x_k z$ to the power $-k+1$ z to the power -1 , this is the term here, okay. And here we have $x_{k+1} z$ to the power $-k$.

So then limit z tends to 1 Z of $x_{k+1}-x_k$ will give you limit z tends to 1 limit k tends to infinity $-x_0 + x_1 z$ to the power $-1+1$ z to the power -1 and so on $x_{n+1} z$ to the power $x_{k+1} z$ to the power $-k$. And this will give you, interchanging limits, limit k goes to infinity z goes to 1 limit z goes to 1 $-x_0 + x_1 z$ to the power $-1+1$ z to the power -1 and so on $x_{k+1} z$ to the power $-k$. And then when z goes to 1, these terms will all go to 0, okay.

Those who contain $1-z$ to the power -1 as a factor, only these 2 terms we will get. This term and this term, okay. So what we will get? Limit k goes to infinity, this will become $-x_0$ and then we have x_{k+1} , okay.

(Refer Slide Time: 50:26)

Final value theorem for z-transform cont...

$$\lim_{z \rightarrow 1} Z[x_{k+1} - x_k] = -x_0 + \lim_{k \rightarrow \infty} x_{k+1} = -x_0 + \lim_{k \rightarrow \infty} x_k \quad (2)$$

On the other hand, applying the real translation property, we have that

$$\begin{aligned} Z[x_{k+1} - x_k] &= z(X(z) - x_0) - X(z) \\ &= (z-1)X(z) - zx_0 \end{aligned}$$

so

$$\begin{aligned} \lim_{z \rightarrow 1} Z[x_{k+1} - x_k] &= \lim_{z \rightarrow 1} ((z-1)X(z) - zx_0) \\ &= \lim_{z \rightarrow 1} (z-1)X(z) - \lim_{z \rightarrow 1} zx_0 \\ &= -x_0 + \lim_{z \rightarrow 1} (z-1)X(z) \quad (3) \end{aligned}$$

ET ROOFTREE MPIL ONLINE CERTIFICATION COURSE 25

So what we get is this. $-x_0$ limit k goes to infinity x_{k+1} , this is the value of limit of z_{k+1} at Z of $x_{k+1}-x_k$ as z goes to 1. Now on the other hand, if you find Z of $x_{k+1}-x_k$. By the advanced property, let us apply this advanced property, this one, okay. Z of y_{n+k} we have found. The Z of y_{n+k} is $z^k * yz$ -sigma $m=0$ to $k-1$. So here if you want Z of y_{n+1} , okay, take $k=1$, so Z of y_{n+1} , when n is greater than or equal to 0, u_n is 1.

So we write u_n as 1, then this is z to the power $1/z$, when k is 1, so m is 0, so we get $y_0 z$ to the power 0, okay. So we get $z^* y z - y_0$. Now in our case, it is the sequence x_{n+1} , x_{k+1} , Z of x_{k+1} will be $z^* X z - x_0$. So we get this here, okay. Z -transform of x_{k+1} is $z^* X z - x_0$, okay by the advanced property. And Z of x_k is $X z$. So this is $z^{-1} * X z - z^* x_0$. This is $z^* x_0$. Now what we have, okay?

So limit z tends to 1 Z of $x_{k+1} - x_k$, okay, this will be equal to this value, when your z goes to 1, this value will tend to $-x_0$, okay because this will tend to 0. So limit z tends to 1, $Z x_{k+1} - x_k$ limit z tends to 1 $z^{-1} X z - z x_0$ which is limit z tends to 1 of this expression - limit z tends to 1 of this expression, so we get $-x_0 + \text{limit } z \text{ tends to } 1$, okay, this will not go to 0 because $X z$ may contain z^{-1} in the denominator. So this is limit z tends to 1 $z^{-1} X z$. So what we will get? This value now can be put as $-x_0 + \text{limit } k \text{ goes to infinity } x_{k+1}$, okay.

Final value theorem for z-transform cont...

Thus from equation (2) and (3) we have

$$-x_0 + \lim_{k \rightarrow \infty} x_k = -x_0 + \lim_{z \rightarrow 1} (z-1)X(z)$$

$\Rightarrow \lim_{k \rightarrow \infty} x_k = \lim_{z \rightarrow 1} (z-1)X(z)$

ET ROOFTOP NPTEL ONLINE CERTIFICATION COURSE 28

So what we will have is? and limit of x_{k+1} as k goes to infinity is same as limit of x_k , so I can also write it as $-x_0 + \text{limit } k \text{ goes to infinity } x_k$, okay. So this value is equal to this value and therefore, this is equal to this. So we get this result here. $-x_0 + \text{limit } k \text{ goes to infinity } x_k = -\text{this}$ and this implies that $\text{limit } k \text{ goes to infinity } x_k = \text{limit } z \text{ tends to } 1 z^{-1} X z$, okay. So this is the final value theorem.

(Refer Slide Time: 53:46)

$$x_2 = \lim_{z \rightarrow \infty} z^2 \left[X(z) - x_0 - \frac{x_1}{z} \right]$$

$$= \lim_{z \rightarrow \infty} \left[z^2 X(z) \right] = \lim_{z \rightarrow \infty} \frac{2z^2 + 5z + 14}{(1 - \frac{1}{z})^4} = 2$$

$$x_1 = \lim_{z \rightarrow \infty} z \left[X(z) - x_0 \right] = \lim_{z \rightarrow \infty} \frac{z(2z^2 + 5z + 14)}{(1 - \frac{1}{z})^4} = 13$$

Example 5

If $X(z) = \frac{2z^2 + 5z + 14}{(z-1)^4}$, evaluate x_2 and x_3 .

$$X(z) = z^{-1} X(z) = \sum_{n=0}^{\infty} x_n z^{-n} = x_0 + \frac{x_1}{z} + \frac{x_2}{z^2} + \frac{x_3}{z^3} + \dots$$

$$x_0 = \lim_{z \rightarrow \infty} X(z) = \lim_{z \rightarrow \infty} \frac{2z^2 + 5z + 14}{(z-1)^4} = \lim_{z \rightarrow \infty} \frac{\frac{2}{z^2} + \frac{5}{z^3} + \frac{14}{z^4}}{(1 - \frac{1}{z})^4} = 0$$

$$x_1 = \lim_{z \rightarrow \infty} z \left[X(z) - x_0 \right] = \lim_{z \rightarrow \infty} \frac{z(2z^2 + 5z + 14)}{(z-1)^4} = \lim_{z \rightarrow \infty} \frac{\frac{2}{z} + \frac{5}{z^2} + \frac{14}{z^3}}{(1 - \frac{1}{z})^4} = 0$$

Ans. $x_2 = 2, x_3 = 13$

Now let me take an example on this initial and final value theorem. Here we are given the Z-transform of a sequence $Xz = 2z^2 + 5z + 14/z - 1$ to the power 4. We want to determine x_2 , okay. So x_2 is, let us look at the result. limit k goes to infinity x_k , okay. So limit, in order to find x_2 , we shall have to determine x_0 first, okay, the initial, this one we will have to determine first, okay.

So we have to go there. See Xz is what? Xz is Z-transform of x_n , okay. So this is $\sum_{n=0}^{\infty} x_n z^{-n}$. So this is $x_0 + x_1/z + x_2/z^2$ and so on, x_3/z^3 and so on, okay. Let me find x_0 first. $x_0 = \lim_{z \rightarrow \infty} z$ tends to infinity, okay, yes. We can do like this. See $x_0 = \lim_{z \rightarrow \infty} z$ tends to infinity Xz , okay. So this will be now limit z tends to infinity $2Xz^2 + 5z + 14/z - 1$ to the power 4, okay.

Now in the denominator we have power of z 4, in the numerator we have power of z as 2. So dividing by z to the power 4 in the numerator and denominator, we write limit z tends to infinity $2/z^2 + 5/z^3 + 14/z^4$ to the power 4 and denominator we have $1 - 1/z$ to the power 4, okay. Now when z goes to infinity, $1/z$ goes to 0. So we get 0, okay. And then we find x_1 . Limit z tends to infinity.

Now what we will do? From Xz , we subtract x_0 and then multiply by z . So we get $Xz - x_0 \cdot z$, then what we get? $x_1 + x_2/z + x_3/z^2$ and so on. So we can determine x_1 , if we take the limit of this

expression. So $x_1 = \lim_{z \rightarrow \infty} z(Xz - x_0)$, okay. So $x_1 = \lim_{z \rightarrow \infty} z(Xz - x_0)$, x_0 is 0. So $\lim_{z \rightarrow \infty} z^*$, again we put the value of Xz , $2z^2 + 5z + 14/z - 1$ to the power 4.

So again we divide by z to the power 4. In the numerator, the power of z , highest power of z is 3, okay. So we will have $\lim_{z \rightarrow \infty} 2/z^5$ and then we have $14/z^5 - 1/z$ to the power 4. And again we get the limit 0, okay. So x_1 is also 0. Now we can find x_2 . x_2 can be found if from Xz we subtract x_0 , then x_1/z and multiply by z^2 and take the limit as z tends to infinity.

So $x_2 = \lim_{z \rightarrow \infty} Xz - x_0 - x_1/z$, okay. So we subtract x_0 , we subtract x_1/z and then multiply by z^2 and take the limit as z tends to infinity, so we will get x_2 . So this is now $\lim_{z \rightarrow \infty} z^2(Xz - x_0 - x_1/z)$. Now x_0 is 0 here, okay. x_1 is 0 here. So we get $\lim_{z \rightarrow \infty} z^2 Xz$ and you can see here Xz , multiply by z^2 here, okay. So we have to multiply by z^2 , okay.

So $\lim_{z \rightarrow \infty} z^2(Xz - x_0 - x_1/z)$. When you multiply this expression by z^2 , the power of z^4 becomes 2. In the denominator, power of z^4 is 1, okay. So we get, when you divide by z to the power 4 in the numerator and denominator and take the limit as z tends to infinity, we will get the limit as 2. So this is z^2 after you multiply and divide by z to the power 4, you get $2 + 5/z$, okay, and then you have $14/z^5 - 1/z$ to the power 4.

And then you take the limit as z goes to infinity, you get the limit as 2, okay. So answer is 2 here, okay. x_2 is 2. And now we have to determine x_3 . So again what we will do? We subtract from Xz , x_0 , x_1/z , x_2/z^2 and then multiply by z^3 , okay.

(Refer Slide Time: 59:53)

So in order to determine x_3 , we have $x_3 = \lim_{z \rightarrow \infty} \frac{z^3}{z^3 - x_0 - \frac{x_1}{z} - \frac{x_2}{z^2}}$, okay. So this is $\lim_{z \rightarrow \infty} \frac{z^3}{z^3 - Xz}$ is this, $2z^2 + 5z + 14$, z^{-1} to the power 4. x_0 is 0, x_1 is 0, x_2 is 2. So $-\frac{2}{z^2}$ square, okay. x_2 is 2. So this gives you $\lim_{z \rightarrow \infty} \frac{z^3}{z^3 - 2z^2 + 5z + 14 - 2z^{-1}}$ to the power 4, okay which is equal to $\lim_{z \rightarrow \infty} \frac{z^3}{z^3 - 2z^2 + 5z + 14 - 2z^{-1}}$ times $2z^2 + 5z + 14 - 2z^{-1}$ to the power 4 $- 4z^3 + 6z^2 - 4z + 1$.

And here we will multiply by z square. Let me multiply by z square. So we have this is equal to limit z tends to infinity z^* , $2z$ to the power 4 will cancel with $2z$ to the power 4, we have $5z$ cube here and here we have $8z$ cube, so $13z$ cube. And we have $14z$ square - $12z$ square, so $2z$ square. $2z$ square + $8z - 2/z - 1$ to the power 4, okay. So this is equal to limit z tends to infinity. When we divide by z to the power 4, we get $13 + 2/z$ cube $((01:03:18))$ to the power 4, so $2/z + 8/z$ square - $2/z$ cube / $1 - 1/z$ to the power 4.

So when z goes to infinity, the limit comes out to be 13. And therefore, the value of x_3 is equal to 13. So x_2 is 2, x_3 is 13. So this is the example on the initial and final value theorem. With this, I would like to end my lecture. Thank you very much for your attention.
