Lecture - 40
Discrete Fourier Transforms - I

Hello friends, welcome to my lecture on Discrete Fourier Transforms. There will be two lectures on this topic; we have at the first lecture now. So in the Discrete Fourier transforms the discrete dataset are converted into a discrete frequency distribution. We shall see that. The discrete dataset are converted into a discrete frequency distribution. Now since the resulting frequency distribution is discrete the computers commonly use discrete Fourier calculation, one frequency information is required.

(Refer Slide Time: 01:01)

Discrete Fourier transforms

In the discrete Fourier transforms, the discrete data sets are converted into a discrete frequency distribution. Since the resulting frequency information is discrete, computers commonly use DFT calculations when frequency information is required. The DFT is a numerical variant of the Fourier transform.

The complex Fourier series of f with period p is given by

$$\sum_{n=-\infty}^{\infty} d_n e^{jn\omega_0 x}, \quad (\omega_0 = \frac{2\pi}{p})$$

where

$$d_n = \frac{1}{p} \int_{-p/2}^{p/2} f(t) e^{-jn\omega_0 t} dt \text{ for } n = 0, \pm 1, \pm 2, \dots$$

The numbers d_n are the complex Fourier coefficients of f .

MPTEL ONLINE
CERTIFICATION COURSE2

Now the DFT is also numerical variant of Fourier transform. Let us see how the motivation for DFT came about. The complex Fourier series of F with period p is given by $\sum_{n=-1}^{\infty} d_n e^{-jn\omega_0 x}$ where ω_0 is suppose to $2\pi/p$. The values of this Fourier coefficients d_n are given by $1/p \int_{-p/2}^{p/2} f(t) e^{-jn\omega_0 t} dt$ when n is taking values $0, +1, +2$ and so on. The numbers d_n 's are called the complex Fourier coefficients of f , since f is given to be p periodic.

(Refer Slide Time: 01:47)

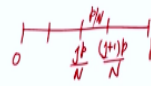

Discrete Fourier transforms cont...

Because of periodicity of f , we may write

$$d_n = \frac{1}{p} \int_0^{p/2} f(t) e^{-in\omega_0 t} dt \text{ for } n = 0, \pm 1, \pm 2, \dots$$

To motivate the definition of DFT, suppose we want to approximate d_n . One way is to subdivide $[0, p]$ into N subintervals of equal length $\frac{p}{N}$ and choose a point t_j in each $[\frac{jp}{N}, \frac{(j+1)p}{N}]$ for $j = 0, 1, 2, \dots, N-1$. Now approximate d_n by Riemann sum

$$\frac{1}{N} \sum_{j=0}^{N-1} f\left(\frac{jp}{N}\right) e^{-2\pi i k j p / N} d_k \approx \frac{1}{N} \sum_{j=0}^{N-1} f(t_j) e^{-2\pi i k t_j / p} \left(\frac{p}{N}\right)$$

$$= \frac{1}{N} \sum_{j=0}^{N-1} f(t_j) e^{-2\pi i k t_j / p} \quad t_j = \frac{jp}{N}$$

We may replace this integral over $-p/2$ to $p/2$ by any other integral where the length of the interval is p , okay, so we can replace integral over $-p/2$ to $p/2$ by integral over 0 to $p/2$, so $dn=1/p$ integral over 0 to p $f(t) e$ to the power $-in \omega_0 t$ dt where $n=0, +1, +2$ and so on. Now to motivate the definition of DFT suppose we want to approximate the value of dn , okay. Suppose we want to; because we have to calculate this integral.

We can consider numerical integration, so if we want to approximate the value of dn , okay then one way is to sub-divide $0p$ interval, okay so $0p$ interval be subdivide into n 's of intervals of equal length p/n and choose a point t_j in each subinterval, jp/n to $j+p/n$ for $j=0, 1, 2$ and so on up to $n-1$. This is your interval $0p$ divided by divided into n 's of intervals of length p/n each. Okay. So suppose your j ; this interval is jp/n $j+1$ and p , okay. The length of each interval is p/n .

So this we do for; I mean this is the j s subinterval where j takes values from 0 to $n-1$. Now approximate this dn by Riemann sum, okay. So $1/p$ sigma $j=0$ to $n-1$ f of t_j , okay t_j is any point in this interval, so f of t_j is to the power $-in \omega_0 t$ is $2\pi i$ over p , okay. So we put $2\pi i$ over p for that and then we have t_j , okay. So we put here kt_j because we want the value of $d(k)$, so $d(k)$ is kt_j here instead of n we are writing k , okay.

So e to the power $-2\pi i kt_j/p$ and then we multiply by the length of the subinterval, so this length is p/n , okay of each interval, the length of each interval is p/n . Okay, so now this is what, this p

will cancel with this p, okay. And take t_j to be let us, okay so here we will take it later the t_j to be jp/n . Let us first simply this, so $1/n$ okay $\sum_{j=0}^{n-1} f(t_j) e^{-2\pi i k t_j / p}$. Now choose t_j to be equal to jp/n . t_j can be any point in this subinterval so we choose t_j to be jp/n . If you choose t_j to be jp/n then what do we get?

(Refer Slide Time: 04:45)

Discrete Fourier transforms cont...

$$= \frac{1}{N} \sum_{j=0}^{N-1} f(t_j) e^{-2\pi i k j / N} \text{ if } t_j = \frac{jp}{N}. \quad (1)$$

Thus, the N-point discrete Fourier transform is defined in such a way that except for the $\frac{1}{N}$ factor, the approximating sum (1) is exactly the N-point discrete Fourier transform of the numbers. Specifically, given a vector of N input amplitudes such as $\{f_0, f_1, f_2, \dots, f_{N-2}, f_{N-1}\}$, the discrete Fourier transform yields a set of n frequency magnitudes. $f_j = f(t_j)$

We get $1/n \sum_{j=0}^{n-1} f(t_j) e^{-2\pi i k j / N}$ if $t_j = jp/N$, okay. Then, what we get here, put t_j to be jp/N so we will get $1/N \sum_{j=0}^{n-1} f(t_j) e^{-2\pi i k j / N}$. This we will cancel, okay. So we will get $1/N \sum_{j=0}^{n-1} f(jp/n) e^{-2\pi i k j / N}$, okay. this is what we get.

Thus, the N-point discrete Fourier transform is defined in such a way that except for the $1/N$ factor, except this $1/N$ factor the approximating sum is exactly the N-point discrete Fourier transform of the numbers, $f(t_0), f(t_1), f(t_2)$ and so on $f(t_{N-1})$ okay. Specifically, we can say given a vector of N input amplitudes say $f_0, f_1, f_2, f_{N-2}, f_{N-1}$. So here I write f_j for $f(t_j)$, okay. $f(t_j)$ I am writing f_j , okay.

So given a vector of an N amplitudes, these are N amplitudes such that $f_0, f_1, f_2, f_{N-2}, f_{N-1}$ the discrete Fourier transform yields a set of n frequency magnitudes. So $\sum_{j=0}^{n-1} f(t_j) e^{-2\pi i k j / N}$ will give us a set of n frequency magnitudes. And the magnitudes will be

given by this dk 's, okay k will run from 0 to $n-1$. So we will get corresponding to n amplitudes, okay we will get n frequency magnitudes, okay.

(Refer Slide Time: 07:07)

Definition

Let N be a positive integer and $u = \{u_j\}_{j=0}^{N-1}$ be a sequence of N complex numbers. Then the N -point DFT of u is the sequence $D[u]$ defined by

$$D[u](k) = \sum_{j=0}^{N-1} u_j e^{-2\pi i k j / N}, \quad k = 0, \pm 1, \pm 2, \dots$$

To simplify the notation, we write

$$U_k = \sum_{j=0}^{N-1} u_j e^{-2\pi i k j / N}, \quad \text{if } u = \{u_j\}_{j=0}^{N-1}$$

$\{u_0, u_1, \dots, u_{N-1}\}$
 $U_k = \sum_{j=0}^{N-1} u_j e^{-2\pi i k j / N}$
 $k = 0, \pm 1, \dots, N-1$
 $U_N = U_0, U_{N+1} = U_1$

So let us see how we define the discrete Fourier transform. Let N be a positive integer and $u = \{u_j\}_{j=0}^{N-1}$ be a sequence of N complex numbers. Then the N -point DFT of u is the sequence $D[u]$ given by $D[u](k) = \sum_{j=0}^{N-1} u_j e^{-2\pi i k j / N}$ where k takes values $0, \pm 1, \pm 2$ and so on, okay you can see here. Here this k taking value infinite number values $0, \pm 1, \pm 2$ and so on.

But you will see that only N out of those infinite number values, only N are distinct remaining are repeated because it turns out that this $D[u][k]$ is a N periodic sequence, okay. So the k value take the value of k from 0 to $N-1$, those frequency magnitudes are distinct others are just repeating, okay because of periodicity of order; periodicity with period N . So here you can see if you compare this definition, this definition if you compare with this definition, okay. Then exact; except this $1/N$ factor remaining sum is the same, okay.

We write $f(t_j) u_j$ here okay and then e to the power exponential function is the same exponential signal e to the power $-2\pi i k j / N$, here also e to the power $-2\pi i k j / N$, j running from 0 to $N-1$, here also j running from 0 to $N-1$, okay. Now we can simplify this notation, $D[u][k]$ we write as U_k ,

so U_k is the discrete Fourier transform of the sequence of n numbers, $u_0, u_1, u_2, \dots, u_{N-1}$. The sequence of numbers is u_0, u_1, \dots, u_{N-1} and they are complex numbers. Okay.

So this is the sequence. Now, let us; so that the N -point DFT, this N -point DFT is periodic with period n . So we need not write infinite number of values of k , we can simply write $k=0, 1, 2, 3$ and so on up to $n-1$, okay. So let us see how it is periodic with period n .

(Refer Slide Time: 09:38)

Now, we show that N -point DFT is periodic of period N . i.e. if $u = \{u_j\}_{j=0}^{N-1}$ then for any integer k , $U_{k+N} = U_k$.

$$\begin{aligned}
 U_{k+N} &= \sum_{j=0}^{N-1} u_j e^{-2\pi i j (k+N)/N} && e^{-2\pi i j k/N} \cdot e^{-2\pi i j N/N} \\
 &= \sum_{j=0}^{N-1} u_j e^{-2\pi i j k/N} e^{-2\pi i j} && e^{-2\pi i j} = \cos(2\pi j) - i \sin(2\pi j) \\
 &= \sum_{j=0}^{N-1} u_j e^{-2\pi i j k/N} && = 1, j=0, 1, \dots, N-1 \\
 &= U_k
 \end{aligned}$$

6

So this is a sequence, okay given sequence of n amplitudes magnitudes and we want to show that $U_{k+N} = U_k$ for any k , okay. U_{k+N} by definition you can see, U_{k+N} is $\sum_{j=0}^{N-1} u_j e^{-2\pi i j (k+N)/N}$, okay. U to the power $-2\pi i j (k+N)/N$, we can separate it into two parts, $e^{-2\pi i j k/N} \cdot e^{-2\pi i j N/N}$. So this N will cancel with this, okay. Now $e^{-2\pi i j}$, this is equal to $\cos 2\pi j - i \sin 2\pi j$, okay. j is an integer, okay.

And when j is an integer $\cos 2\pi j = 1$; $\sin 2\pi j = 0$, so this is equal to 1, okay when j varies from 0 to $n-1$, okay. So this becomes this quantity, this quantity becomes $e^{-2\pi i j k/N}$, okay. This is equal to 1, okay. So we get this, and this is equal to U_k . So the U_k , U_k is discrete Fourier transform is N periodic and therefore, U_k is equal to this; we can write $U_k = \sum_{j=0}^{N-1} u_j e^{-2\pi i j k/N}$ where k vary from 0 to 1, 2 and so on up to $N-1$, okay.

Because U_n will be nothing but U_0 . U_{n+1} will be equal to U_1 , okay like this. Okay, so when you take $k=n$ or you take $k=n+1$ and so on this will be simply U_0, U_1, U_2 and so on, so it will repeat. Similarly, for negative values of K .

(Refer Slide Time: 12:06)

Relation of DFT to DTFT

If we take the DTFT of a given time sequence $\{x_n\}_{n=-\infty}^{\infty}$ we get a continuous-frequency function

$$X(e^{j\omega}) = \sum_{n=-\infty}^{\infty} x_n e^{-j\omega n}$$

where IDTFT is given by

$$x_n = \frac{1}{2\pi} \int_{-\infty}^{\infty} X(e^{j\omega}) e^{j\omega n} d\omega$$

If we sample $X(e^{j\omega})$ at N equally-spaced locations $\omega_k = \frac{2\pi k}{N}$, $k = 0, 1, 2, \dots, N-1$, the result is the DFT X_k .

Handwritten notes on the slide:

- $X_k = \sum_{n=0}^{N-1} x_n e^{-j2\pi kn/N}$
- $X(e^{j\omega_k}) = \sum_{n=-\infty}^{\infty} x_n e^{-j2\pi kn/N}$
- $X(e^{j(\omega_k + 2\pi)}) = \sum_{n=-\infty}^{\infty} x_n e^{-j(\omega_k + 2\pi)n} = \sum_{n=-\infty}^{\infty} x_n e^{-j\omega_k n} e^{-j2\pi n} = \sum_{n=-\infty}^{\infty} x_n e^{-j\omega_k n} = X(e^{j\omega_k})$
- $e^{-j(\omega_k + 2\pi)n} = e^{-j\omega_k n} \cdot e^{-j2\pi n} = e^{-j\omega_k n} \cdot 1 = e^{-j\omega_k n}$

Now let us see how the discrete Fourier transform is related to the discrete time Fourier transform. If we take the discrete time Fourier transform of a given sequence x_n from $n = -\infty$ to $n = \infty$ we get a continuous-frequency distribution, okay. Continuous-frequency distribution we get and it is defined as $X(e^{j\omega}) = \sum_{n=-\infty}^{\infty} x_n e^{-j\omega n}$. With inverse IDTFT, okay this is inverse DTFT – Discrete Time Fourier Transform.

This is Discrete Time Fourier Transform; this is Inverse Discrete Time Fourier Transform. So inverse discrete time Fourier transform is given by $x_n = \frac{1}{2\pi} \int_{-\infty}^{\infty} X(e^{j\omega}) e^{j\omega n} d\omega$. Here you can see that, $X(e^{j\omega})$ is a continuous frequency distribution, we are considering integral, okay. So it is a continuous frequency distribution and it is 2π periodic $X(e^{j\omega})$ you can see, $X(e^{j(\omega + 2\pi)})$ if you consider, okay.

Then this is $\sum_{n=-\infty}^{\infty} x_n e^{-j\omega n} e^{j2\pi n} = \sum_{n=-\infty}^{\infty} x_n e^{-j\omega n} = X(e^{j\omega})$. So this is $e^{-j\omega n} e^{j2\pi n} = e^{-j\omega n} \cdot 1 = e^{-j\omega n}$. This value is

equal to 1, so we have e to the power $-i \omega n$, so this is equal to σ , that is $x \omega e i$ ω . So it is continuous frequency distribution with period 2π , okay.

Now, if you, if we sample $X e i \omega$ at N equally-spaced locations $\omega_k = 2\pi I; 2\pi k/n$, okay. k varies from 0 to $n-1$, the result will be DFT X_k . Now let us see, how we get that. See here you take, $X e i \omega_k$, okay. So this is $\sum_{n=-\infty}^{\infty} X_n e$ raise to the power $-i \omega_k n$, so we have $2\pi I, kn/n$, okay, $2\pi kn/n$.

Now, X_n is defined only for this range, okay 0 to $N-1$, okay. So this sum will be reducing to; when we replace $X e$ to the power; okay $X e$ to the power $i \omega_k n$ we consider as X_k , okay. $X_k = \sum_{n=-\infty}^{\infty} X_n e$ raise to the power $-2\pi i kn/n$, okay so we take $\omega_k = 2\pi i k/n$ okay. And consider this at equally-spaced locations, okay equally-spaced locations. And these are N equally-spaced locations, okay.

So then the sequence X_n is taken to be define for N value from 0 to $N-1$. Okay. So this will be X_k , X_k will be $\sum_{n=0}^{N-1} X_n e$ raise to the power $-2\pi i kn/n$ okay and which is nothing but DFT, DFT of X_n sequence. So X_n sequence is given for $n=0,1,2,3$ and so on up to $N-1$, okay and remaining values we can take as 0s then this X_n then this $X e i \omega$ reduces to DFT. Okay.

(Refer Slide Time: 16:44)

Matrix method

Let $W_N = e^{-2\pi i/N}$ then $X_k = \sum_{n=0}^{N-1} x_n W_N^{kn}$, equivalently, $X = D_N X$, where x is the time domain sequence arranged as $N \times 1$ column vector and X is the resulting frequency information. The D_N matrix is called the twiddle matrix and is defined as

$$X_k = \sum_{n=0}^{N-1} x_n e^{-2\pi i kn/N}$$

$$= \sum_{n=0}^{N-1} x_n W_N^{kn}$$

$$D_N = [W_N^{kn}]$$

$$\begin{bmatrix} 1 & 1 & 1 & \dots & 1 \\ 1 & W_N^1 & W_N^2 & \dots & W_N^{N-1} \\ 1 & W_N^2 & W_N^4 & \dots & W_N^{2(N-1)} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 1 & W_N^{N-1} & W_N^{2(N-1)} & \dots & W_N^{(N-1)(N-1)} \end{bmatrix}$$

$$X = \begin{bmatrix} x_0 \\ x_1 \\ \vdots \\ x_{N-1} \end{bmatrix}$$

$$X = \begin{bmatrix} x_0 \\ x_1 \\ \vdots \\ x_{N-1} \end{bmatrix} = D_N \begin{bmatrix} x_0 \\ x_1 \\ \vdots \\ x_{N-1} \end{bmatrix}$$

$D_N \rightarrow N \times N$ matrix

where $k, n = 0, 1, 2, \dots, N-1$.

8

So let us now consider, there is another method of computing the discrete Fourier transform. This is by Matrix method. Let us denote, W_N to the power $-2\pi i/N$ by W_N . We have $X_k = \sum_{n=0}^{N-1} x_n e^{-2\pi i kn/N}$, okay $2\pi i kn/N$. So $e^{-2\pi i kn/N}$ denoted by W_N^{kn} , so this is $\sum_{n=0}^{N-1} x_n W_N^{kn}$. Okay. $x_n W_N^{kn}$.

So this is what we get, okay. $X_k = \sum_{n=0}^{N-1} x_n W_N^{kn}$ and equivalently we can write it in the form of a matrix equation, $X = D_N x$, okay. So x is this vector, X is column vector, X_0, X_1 and so on X_{N-1} , because k takes values from 0 to $N-1$, so we get here X_0, X_1, \dots, X_{N-1} . This equal to $D_N x$, okay. D_N is this matrix, multiplied by x . This small x is the time domain sequence; time domain sequence is that x_n sequence. Okay. So X_0, X_1, \dots, X_{N-1} .

Okay. So X is this one, x is this one, okay. Capital X is the frequency, resulting frequency formation, column vector, this frequency information and this $N/1$ column vector is the time domain sequence okay. So X is this one, okay so we have like this. X_0, X_1, \dots, X_{N-1} equal to D_N sequence matrix $\times x$, okay. So this D_N is N/N matrix, okay. This is $N/1$ matrix, this is also $N/1$ matrix, D_N is N/N matrix, okay. Okay, so this X_k can be written in this form, okay. We let see how we are writing it, okay.

(Refer Slide Time: 19:37)

$$X_k = \sum_{n=0}^{N-1} x_n W_N^{kn} \quad \begin{matrix} k=0, 1, \dots, N-1 \\ n=0, 1, \dots, N-1 \end{matrix}$$

$$X = \begin{bmatrix} X_0 \\ X_1 \\ \vdots \\ X_{N-1} \end{bmatrix}, \quad x = \begin{bmatrix} x_0 \\ x_1 \\ \vdots \\ x_{N-1} \end{bmatrix}$$

$$D_N = \begin{bmatrix} 1 & 1 & 1 & \dots & 1 \\ W_N & W_N^2 & W_N^4 & \dots & W_N^{N-1} \\ W_N^2 & W_N^4 & W_N^8 & \dots & W_N^{2(N-1)} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ W_N^{N-1} & W_N^{N-2} & W_N^{N-4} & \dots & W_N^{(N-1)(N-1)} \end{bmatrix}$$

$$W_N = e^{-2\pi i/N}$$

$$W_N^{kn} = e^{-2\pi i kn/N}$$

$$W_N^{00} = 1$$

$$W_N^{kn} = 1 \text{ when } k=0$$

$$W_N^{kN} = 1 \text{ when } n=0$$

Where $X_k = \sum_{n=0}^{N-1} x_n W_N^{kn}$, okay. Now, let us see how we write it. See, X is this one, X_0, X_1, \dots, X_{N-1} , okay. And small x is small x vector is that time domain sequence, so $x_0, x_1,$

x_{n-1} , all right. Now, so we let us write D_n sequence, okay. D_n matrix will be, okay. So; see k varies on this W_n^{Kn} , K varies along the rows, and n varies along the columns. So n varies along the columns and k varies along the rows. So first we write when $k=0$, $n=0$.

K varies from 0 to $n-1$ and n also varies from 0 to $n-1$. Okay. So when, okay, so when this is 0,1,2 and so on $n-1$ column, okay. Here $k=0$ then $k=1$ and then $k=2$ and then $k=n-1$ as row, okay. So when k is 0, n is 0. W_n^{00} . W_n ; we have taken W_n to be equal to e to the power $-2\pi i/n$, okay. So $W_n^{Kn} = e$ to the power $-2\pi i/n * Kn$, okay. So when $K=0$ $n=0$. We will have W_n^{00} . $W_n^{00} = W_n^{Kn}$ is 0, so e to the power 0 is 1, so we get first element 1.

Now in the first row k is 0, okay. So k is 0 means $W_n^{Kn}=1$ when $k=0$. So all elements are 1, okay. Similarly, $W_n^{Kn} = 1$ when $n=0$, okay. That is 0; first column okay. So 1 1 and so on 1, okay. Then you have, in this first row, okay $k=1$ and then $1=1$ so we get W_n^{11} , okay W_n^{11} product I overwriting okay. $1*1$ is W_n^1 . Then you write $W_n^{K=1 N=2}$ so you get W_n^2 and so on, W_n^{K*N} . K is 1 N is $N-1$ so we get $N-1$. Here $K=2$ okay, $K=2 N=1$ so we get W_n^2 .

Then $K=2 N=2$, so W_n^4 . Okay. And so on we get $K=2$, $N=N-1$ so W_n two times $N-1$, okay. And then we can similarly write last row okay. $K=N-1$, $N=1$, so we get W_n^{n-1} . Then $K=N-1 N=2$ so W_n^{N-2} and so on. We get W_n lastly. K is $n-1$; N is $n-1$ so $N-1 N-1$. Okay. This is how we write the matrix D_n . If this matrix D_n when multiplied by X_0, X_1, X_2, X_{n-1} equated to this column vector, this give us the all n equations here, okay there are n equations $K=0, 1, 2$ and so on up to $N-1$, okay.

So we write these n equations in the form of a matrix equation, like we do in the case of solution of a system of linear equations okay. So here, this is the matrix. This when you write this DFT in the matrix form it is easy to compute as we said by examples, so let us now move onto examples.

(Refer Slide Time: 24:28)

Example 1

Let us consider a 3-point DFT

Solution: We are given $N = 3$, hence $X_k = \sum_{n=0}^{N-1} x_n e^{-j2\pi kn/3}$, $k = 0, 1, 2$, then the twiddle matrix

N-point DFT
not that
 $W_N^N = 1$
or
 $W_N^{N+2} = W_N^2$
 $W_3^3 = W_3^0 = 1$
 $W_3^4 = W_3^1$
 $W_3^5 = W_3^2$
 $W_3^6 = W_3^0 = 1$

$$D_N = D_3 = \begin{bmatrix} 1 & 1 & 1 \\ 1 & W_3^1 & W_3^2 \\ 1 & W_3^2 & W_3^4 \end{bmatrix} = (W_N^{kn})_{k=0,1,2; n=0,1,2}$$

$$D_3 = \begin{bmatrix} 1 & 1 & 1 \\ 1 & -\frac{1}{2} - \frac{j\sqrt{3}}{2} & -\frac{1}{2} + \frac{j\sqrt{3}}{2} \\ 1 & -\frac{1}{2} + \frac{j\sqrt{3}}{2} & -\frac{1}{2} - \frac{j\sqrt{3}}{2} \end{bmatrix}$$

Handwritten notes:
 $N=3$
 $W_3^2 = e^{-j2\pi/3}$
 $W_3^4 = e^{-j4\pi/3} = e^{j2\pi/3}$
 $W_3^3 = e^{-j2\pi} = 1$
 $W_3^4 = W_3^1$
 $W_3^5 = W_3^2$

Let us consider a 3-point DFT, okay. 3-point DFT means $N=3$. Okay. This DFT is called as N-point DFT, okay. So we are given $N=3$, okay. Now X_k therefore, $\sum_{n=0}^{N-1} x_n e^{-j2\pi kn/3}$, $k=0,1,2$. So then the twiddle matrix. This is called as the twiddle matrix, this matrix D , is called the twiddle matrix. Okay.

So twiddle matrix $D_N = D_3$ will be $\begin{pmatrix} 1 & 1 & 1 \\ 1 & W_3^1 & W_3^2 \\ 1 & W_3^2 & W_3^4 \end{pmatrix}$ okay. So $1 \ 1 \ 1; 1 \ W_3^1 \ W_3^2; 1 \ W_3^2 \ W_3^4$, okay so this is what you get. $N=3$. So $1 \ 1 \ 1; 1 \ W_3^1 \ W_3^2; 1 \ W_3^2 \ W_3^4$. As I said here, k varies along the rows and N varies along the columns, okay. And is the matrix W_N^{kn} , okay. k varies along the columns from 0 to $n-1$ and n varies along the rows; n varies along the columns. Okay, now let us note one thing. $W_N = e^{-j2\pi i/n}$ okay.

So, okay $N=3$, so W_3^3 will be $e^{-j2\pi i/3}$ raised to the power 3, okay. W_3^3 . W_N^{kn} means W_N raised to the power kn , okay. So W_3^3 to the power 3 will be $e^{-j2\pi i}$, so we get equal to 1, okay. W_3^4 raised to the power 4, okay. W_3^4 raised to the power 4 when we have, we can write it as $W_3^3 \cdot W_3^1$, okay. So W_3^3 raised to the power 3 is 1, so we can write it as W_3^1 , okay.

So when we have N-point DFT in; for N-point DFT we have to note that $W_N^n = 1$, okay. $W_N^n = 1$. So any power of W_N more than n okay can be reduced to a power less than n , okay. W_N^n say W_N^n raised to the power $n+2$, okay if you have. You can write it as W_N^2 , okay. So

here, we have W_{31} , W_{32} , W_{34} , W_{34} will be equal to $W_{33} \cdot W_{31}$ okay. And W_{33} is 1 so we get W_{31} . Okay. So this will be, this matrix will be $\begin{bmatrix} 1 & 1 & 1 & 1 \\ 1 & W_{31} & W_{32} & W_{33} \end{bmatrix}$; W_{32} and then W_{31} , okay.

If we have a N -point DFT the power of W_N ; if it is n it will be 1, if it is more than n it will be, can be reduced to power less than 1, less than n okay. Now, let us see what is W_{31} . $W_{31} = W_3$ is e to the power $-2\pi i/3$, so it is $\cos 2\pi i/3 - i \sin 2\pi/2$ and its value is $\cos 2\pi/3$ is -1 $\sin 2\pi/3$ is $\sqrt{3}/2$, so $-i \sqrt{3}/2$. Okay. So this is W_{31} . And W_{32} , W_{32} is e to the power $-2\pi i/3$ raise to the power 2. So e to the power $-4\pi i/3$.

So this is \cos for $\pi/3 - i \sin 4\pi/3$. $\cos \pi/3$ is $\cos 4\pi/3$ is $\cos \pi + \pi/3$ so that is $-\cos \pi/3$. And $-\cos \pi/3$ is $-1/2$, okay. $\sin 4\pi/3$ is $\sin \pi + \pi/3$ which will be $-\sin \pi/3$ is $-\sqrt{3}/2$ so this is $+i \sqrt{3}/2$. Okay. So you get this value. So W_{31} is this, W_{32} is this, W_{32} is same, this is $-1/2 + i \sqrt{3}/2$, we have calculated already and this W_{34} we have seen, W_{34} is W_{31} . W_{31} we have already found, this is $-1/2 - i \sqrt{3}/2$. So this is how we calculate D_3 .

(Refer Slide Time: 30:09)

Example 2

If $N = 4$ then $X_k = \sum_{n=0}^3 x_n W_N^{kn}$. Hence the twiddle matrix

$$D_N = D_4 = \begin{bmatrix} 1 & 1 & 1 & 1 \\ 1 & W_4^1 & W_4^2 & W_4^3 \\ 1 & W_4^2 & W_4^4 & W_4^6 \\ 1 & W_4^3 & W_4^6 & W_4^9 \end{bmatrix}$$

Now, $W_4^1 = -i$, $W_4^2 = -1$, $W_4^3 = i$, $W_4^4 = 1$, $W_4^5 = -i$, $W_4^6 = -1$, $W_4^7 = i$.
Thus

$$D_4 = \begin{bmatrix} 1 & 1 & 1 & 1 \\ 1 & W_4^1 & W_4^2 & W_4^3 \\ 1 & W_4^2 & W_4^4 & W_4^6 \\ 1 & W_4^3 & W_4^6 & W_4^9 \end{bmatrix} = \begin{bmatrix} 1 & 1 & 1 & 1 \\ 1 & -i & -1 & i \\ 1 & -1 & 1 & -1 \\ 1 & i & -1 & -i \end{bmatrix}, W_4^0 = W_4^4 = 1$$

Now, let us consider 4-Point DFT. When you consider 4-Point DFT that is $N=4$, X_k will be $\sum_{n=0}^3 x_n W_N^{kn}$, okay. Twiddle matrix will be what, again let us see, let me write twiddle matrix for $N=4$, okay.

(Refer Slide Time: 30:27)

$$\begin{aligned}
 N=4 \\
 \text{Twiddle matrix} &= (W_N^{kn}), \quad k=0, \dots, n-1 \\
 &\quad n=0, \dots, n-1 \\
 D_N &= \begin{bmatrix} 1 & 1 & 1 & 1 \\ 1 & W_N^1 & W_N^2 & W_N^{N-1} \\ 1 & W_N^2 & W_N^4 & W_N^{2(N-1)} \\ 1 & W_N^{N-1} & W_N^{2(N-1)} & W_N^{(N-1)(N-1)} \end{bmatrix} \\
 &= \begin{bmatrix} 1 & 1 & 1 & 1 \\ 1 & W_N^1 & W_N^2 & W_N^3 \\ 1 & W_N^2 & W_N^4 & W_N^6 \\ 1 & W_N^3 & W_N^6 & W_N^9 \end{bmatrix} = \begin{bmatrix} 1 & W_N^1 & W_N^2 & W_N^3 \\ 1 & W_N^2 & W_N^4 & W_N^6 \\ 1 & W_N^3 & W_N^6 & W_N^9 \\ 1 & W_N^4 & W_N^8 & W_N^{12} \end{bmatrix} \\
 &= \begin{bmatrix} 1 & 1 & 1 & 1 \\ 1 & -i & -1 & i \\ 1 & -1 & 1 & -i \\ 1 & i & -1 & -i \end{bmatrix} \\
 W_N^1 &= e^{-j2\pi/4} \\
 &= e^{-j\pi/2} \\
 &= \cos\frac{\pi}{2} - j\sin\frac{\pi}{2} \\
 &= -j \\
 W_N^2 &= (-j)^2 = -1 \\
 W_N^3 &= (-j)^3 = -(-j)j = j \\
 W_N^4 &= (-j)^4 = 1
 \end{aligned}$$

So twiddle matrix, okay. So this equal to W_N^{kn} . Okay. Where k runs from 0 to $n-1$ and n runs from 0 to $n-1$. As I said, twiddle matrix D_N be denoted by D_N and D_N is given by, okay. So k varies along the rows, okay this is $k=0, k=1, k=2, k=3$ and so on $k=n-1$ of row. And here $n=0^{\text{th}}$ column $n=1$ column, 2, $n=n-1$. So $n=0$ is the first column, $n=1$ is the second column okay. W_N^{k*n} , $k*n$ when k is 0 or n is 0. Okay. W_N to the power 0 means 1, okay.

So this is 1, this is 1, this is 1, 1, okay. Either k is 0 or n is 0. And then when n is 0 in the first column we also have 1. Then, first $k=1, n=1$ so we get W_N to the power 1. When k is 1, n is 2 we get W_N to the power 2, okay. When k is 1, $W_N^{n=n-1}$ we get W_N to the power $n-1$, okay because k is 1. Then, k is 2 so we get W_N^{2*n} is 1, okay. Then, W_N^{2*2} that is 4. And then W_N^{2*n-1} and so on. Lastly, we write $n-1$. So W_N , okay k is $n-1, n$ is 1 so we get $n-1$. k is $n-1$, this n is 2, so two times $n-1$. And we get W_N^{n-1} , sorry $W_N^{n-1 * n-1}$. Then we put $n=4$ in this; this general matrix.

So 1 1 1 1; 1 1 1 1 okay then we get W_4^{11} okay W_4^{12} and we get $N=4, W_4^{13}$, okay $N=4$. Then we get W_4^{14} then we get $N=4$, so this is W_4^{16} , okay. Then 1 W_N to the power 3, W_N to the power $4-1$ so that is $4*2$; no $4-1$ is 3, $3*2$ is 6. And then $4-1$ is 3, $3*3$ 9 so W_4^9 , okay. Now, we can reduce it using the fact that W_N to the power $n=1$, okay. So this can be written as further 1 1 1 1; 1 W_4 W_4^2 W_4^3 then 1 W_4 this N should be 4 here, okay everywhere.

Okay, W42 W42. W44 is 1, okay W44 is 1. W46 is W42 then 1 W43 then W46 is W42 okay and this W49, W49 is W44 * W44 * W41, so W41, okay. W49 = W44 * W44 * W41. Okay. Now W41 is how much? W41 is e to the power $-2\pi i/4$. Okay raise to the power 1 because Wn is e to the power $-2\pi i/n$, okay. So this is e to the power $-\pi i/2$ so this is $\cos \pi/2 - i \sin \pi/2$ so this is $-i$, okay. Then W42, okay. W42 you want. Okay, W42 is W41 square, okay.

So $-i$ square. So this is i square is -1 , so we get -1 . W4 cube, W4 cube is $-i$ whole cube, okay. So $-i$ whole cube means -1 whole cube is $-$, okay. i cube is i square * i . i square is -1 * i so $+i$. Okay. So we get the value of W41, W42, W43 okay. So let us put these values, so then what do we get? The matrix as $1 \ 1 \ 1 \ 1$; $1 \ 1 \ 1$; W41, W41 is $-i$ W42, W42 is -1 W43 is i okay. And then W42, W42 is -1 , W41, W44 is 1 okay, W42 W42 is -1 okay.

And then W43, W43 is i , okay W42, W42 is -1 and W41, W41 is $-i$. So let us see whether we have this same matrix here. Okay, so we have, we have this matrix, okay. D4 is this matrix. W40, W40 is nothing but W44. Okay. So this is equal to 1. All right. So let us see whether we have this same values or not.

(Refer Slide Time: 37:03)

Example 3

In particular, if $x_n = \{1, -1, i, -i\}$ then using matrix method

$$\begin{bmatrix} X_0 \\ X_1 \\ X_2 \\ X_3 \end{bmatrix} = \begin{bmatrix} 1 & 1 & 1 & 1 \\ 1 & -i & -1 & i \\ 1 & -1 & 1 & -1 \\ 1 & i & -1 & -i \end{bmatrix} \begin{bmatrix} 1 \\ -1 \\ i \\ -i \end{bmatrix} = \begin{bmatrix} 0 \\ 2 \\ 2+2i \\ -2i \end{bmatrix}$$

$= \begin{bmatrix} 1-1+1-1 \\ 1+i-1+i \\ 1+1-1-1 \\ 1-i-1+i \end{bmatrix} = \begin{bmatrix} 0 \\ 2 \\ 2+2i \\ -2i \end{bmatrix}$

$X_0 = 0$
 $X_1 = 2$
 $X_2 = 2+2i$
 $X_3 = -2i$

11

We have X0, X1, X2, X3 this is the left hand side frequency they may have some column, this is the amplitude column, this one. We are taking an example here. Here you can put the values, okay. Let me see; I have not put the values here. This is equal to, if you put these values which I

have calculated, this is equal to $1 \ 1 \ 1 \ 1$ and then you get 1 and $W41=-i$ and $W42=-1$; $W43=i$, okay. And then we have $1 \ W42=-1$, $W40=1$; $W42$, $W42=-1$, okay.

And then we have 1, $W43$ is i , $W42$ is -1 and $W41$ is $-i$. So let us see, first row; first column they always 1. In the second row we have $1 \ -i \ -1 \ i$, okay. $1 \ -1 \ -1 \ i$. $1 \ -i \ +1 \ i$, so okay. Then, we have here $1 \ -1 \ 1 \ -1$; so we have $1 \ -1 \ 1 \ -1$ and then we have $1 \ i \ -1 \ -i$; $1 \ i \ -1 \ -i$, okay. So this is how we calculate this $D4$. Now let us take an amplitude matrix and let us determine the corresponding frequency matrix, okay. So this time domain, okay time is but $1 \ -1 \ i \ -i$ okay.

So $1 \ -1 \ i \ -i$ and these are the values of; this $D4$ matrix. Let us check. So we multiply by $1 \ -1 \ i \ -i$ to this matrix and what you get in the numerator, what you get here; this matrix as $1 \ -1 \ +1 \ -i$ okay when you multiply this column to first row. When you multiply this column to second row what you get, 1 and $-i * -1$, so we get $+i$ and $-1 * i$ is $-i$ $1 \ -i * i$ is $-i$ square so $+1$.

Okay. And then when, you can multiply to this here $1 \ -1 \ -1$ is $+1$ and then here i we have and here we get $+i$, okay. So then we get similarly last column, last row we multiply by this and we get 1 then we get $-i$, we get $-i$, we get $+i$ square, so -1 okay. So this cancels with this, this cancels with this and this cancels with this. And here we have 1 cancels with 1.

So this is what you have. 0 and then you have 2 you have $2+2i$ and we have $-2i$, okay. So this is what we get. So $X0$, $X0 = 0$, okay $X1=2$; $X2=2+2i$ and then $X3=-2i$, so we can get the frequency of magnitudes when you know the time amplitude, okay. So let us consider the constant sequence. Suppose we are given the constant sequence.

(Refer Slide Time: 40:58)

Example 4

Let us consider the constant sequence $u = \{c\}_{j=0}^{N-1}$ where c is a complex number. Then $U_k = \sum_{j=0}^{N-1} c e^{-2\pi i j k / N} = 0$, for $k = 0, \pm 1, \pm 2, \dots$

$$\begin{aligned} U_k &= \sum_{j=0}^{N-1} c e^{-2\pi i j k / N} \\ &= c \left[\frac{1 - (e^{-2\pi i k / N})^N}{1 - e^{-2\pi i k / N}} \right] = c \left[\frac{1 - e^{-2\pi i k}}{1 - e^{-2\pi i k / N}} \right] = 0, \text{ as } e^{-2\pi i k} = 1. \end{aligned}$$

$u = (u_j)_{j=0}^{N-1} = (c)_{j=0}^{N-1}$

U_j , here $u=c$; $j=0$ to $10-1$. We have taken $u=(u_j)$ okay $j=0$ to $n-1$ as the sequence. So here we are given u_j as c for all j , okay. So if you want here U_k , $U_k = \sum_{j=0}^{n-1} u_j e^{-2\pi i j k / n}$, okay. C can be taken outside because it is constant and then this is a geometric series, okay. This is a geometric series, you can see.

And the ratio is e to the power $-2\pi i k/n$ okay, geometric ratio, r is e to the power $-2\pi i k/n$. So we can sum it up, sum will be $1 - e$ raise to the power $-2\pi i k/n$ because there are n terms, so raise to the power $n/1 - e$ raise to the power $-2\pi i k/n$, okay. Now here what will happen, this is c times $1 - e$ raise to the power $-2\pi i k/n$ so we get e to the power $-2\pi i k/1 - e$ raise to the power $-2\pi i k/n$. And k is an integer, okay.

So e to the power $-2\pi i k$ will be equal to 1 , okay. So this is 0 , okay. As e raise to the power $-2\pi i k/1 = 1$, okay. So if we take constant sequence then it is discrete for a transform is 0 for all values of k . Okay. k is taking; we are taking writing here $+1 -1 + -2$ and so on as we have already seen U_k is a n periodic sequence, so we can reduce this k to $0, 1, 2, 3$ and so on up to $n-1$. Okay. Now let us we take another example.

(Refer Slide Time: 43:13)

Example 5

Let $x_n = a^n$, where a is a complex number.

Then

$$D(\{x_n\})(k) = \sum_{n=0}^{N-1} a^n e^{-2\pi i n k / N} = \sum_{n=0}^{N-1} \left(a e^{-2\pi i k / N} \right)^n = \sum_{n=0}^{N-1} r^n$$

$$= \begin{cases} N & \text{if } a = e^{2\pi i k / N} \\ \frac{1-a^N}{1-a e^{-2\pi i k / N}} & \text{otherwise,} \end{cases}$$

$k = 0, 1, 2, \dots, N-1.$

Handwritten notes:
 If $a \neq e^{2\pi i k / N}$ we have $(1-a^N)/(1-a e^{-2\pi i k / N})$.
 If $a = e^{2\pi i k / N} \Rightarrow D(\{x_n\})(k) = \sum_{n=0}^{N-1} 1 = N$.

Suppose X_n is a to the power n . Here a is a complex number. Then, the discrete Fourier transform of the sequence X_n , k is given by $\sum_{n=0}^{N-1} a^n e^{-2\pi i n k / N}$. And this can be written as $\sum_{n=0}^{N-1} a e^{-2\pi i k / N}$ whole to the power n , okay. So this is a geometric series again, okay. So sum will be $1 - a e^{-2\pi i k / N}$ whole to the power N , okay divided by $1 - a e^{-2\pi i k / N}$, okay.

Now this will be equal to; if $a = e^{2\pi i k / N}$ okay if $a = e^{2\pi i k / N}$ yeah okay here, you can see. Here you can see that, if $a = e^{2\pi i k / N}$ okay. We can divide by this only when a is not equal to $e^{2\pi i k / N}$. If $a = e^{2\pi i k / N}$ then this will be equal to N , okay and we will $\sum_{n=0}^{N-1} 1$ which is equal to N . So if $a = e^{2\pi i k / N}$ then we get the X_n $k=n$ for all k values of k okay.

And if a is not equal to $e^{2\pi i k / N}$ then we get this. So here, when you raise to power n we get $1 - a$ to the power N because $e^{-2\pi i k}$ will be equal to 1 , so we get the if a is not equal to $e^{2\pi i k / N}$, this is here we are taking a not equal to $e^{2\pi i k / N}$ okay, so then we get $1 - a$ to the power $N / 1 - a e^{-2\pi i k / N}$. And if, as I said if $a = e^{2\pi i k / N}$ we get the value N . Dx_n $k=n$ for all k . Okay. So this is how we do this problem.

(Refer Slide Time: 46:28)

Example 6

Let $x_n = \binom{N-1}{n}$, $n = 0, 1, 2, \dots, N-1$, then $D(\{x_n\})(k) = X_k$.
Since,

$$\begin{aligned} D(\{x_n\})(k) = X_k &= \sum_{n=0}^{N-1} x_n e^{-2\pi i k n / N} \\ &= \sum_{n=0}^{N-1} \binom{N-1}{n} e^{-2\pi i k n / N} = \sum_{n=0}^{N-1} \binom{N-1}{n} (\underbrace{e^{-2\pi i k / N}}_{\alpha})^n \\ &= (1 + e^{-2\pi i k / N})^{N-1} = (1 + \alpha)^{N-1} = (1 + e^{-2\pi i k / N})^{N-1} \end{aligned}$$

If X_n is the binomial coefficient $\binom{N-1}{n}$, okay then X_k , X_k is again D of X_n at k okay. So that we are writing as X_k , $\sum_{n=0}^{N-1} X_n e^{-2\pi i k n / N}$, so this is $\sum_{n=0}^{N-1} \binom{N-1}{n} e^{-2\pi i k n / N}$. And this can be regarded as $\sum_{n=0}^{N-1} \binom{N-1}{n} e^{-2\pi i k n / N}$ raise to the power n , okay so then this by binomial theorem this is nothing but $1 + \alpha$; if it is suppose α then $1 + \alpha$ to the power $N-1$, okay.

α is $e^{-2\pi i k / N}$, okay. So this is $1 + e^{-2\pi i k / N}$; this I am writing as α . Okay. Okay, so this how we can do this problem. Again, for $k=0, 1, 2, 3$ and so on up to $N-1$.

(Refer Slide Time: 47:48)

Example 7

Let $x_n \in \mathbb{R}$ then $D(\{x_n\})(k) = X_k = \sum_{n=0}^{N-1} x_n e^{-2\pi i k n / N}$.

Hence,

$$\bar{X}_k = \sum_{n=0}^{N-1} \bar{x}_n e^{2\pi i k n / N} = \sum_{n=0}^{N-1} x_n e^{2\pi i k n / N} \quad \text{as } x_n \text{ is real so } \bar{x}_n = x_n$$

Thus,

$$\begin{aligned} \bar{X}_{N-k} &= \sum_{n=0}^{N-1} x_n e^{2\pi i (N-k)n / N} = \sum_{n=0}^{N-1} x_n e^{2\pi i n - 2\pi i k n / N} \\ &= \sum_{n=0}^{N-1} x_n e^{-2\pi i k n / N} \quad \text{as } e^{2\pi i n} = \cos(2\pi n) + i \sin(2\pi n) = 1 \\ &= X_k \end{aligned}$$

Now if; this is a very important question. If X_n is real sequence, we are going to show that, if X_n is a real sequence then discrete sequence of X_n is also real, okay. So let X_n belong to \mathbb{R} then then $X_n = X_k = \sum_{n=0}^{N-1} x_n e^{-j2\pi kn/N}$ by definition we have this, okay. Hence, let us take the conjugate of X_k . We want to show that X_k is real for every k , so let us take conjugate of this and we shall then show that $\overline{X_k} = X_k$ for every k .

So $\overline{X_k} = \sum_{n=0}^{N-1} \overline{x_n e^{-j2\pi kn/N}}$ and the conjugate of e to the power $-2\pi ik/n$ is e to the power $2\pi ik/n$, okay. Now, X_n is real, $\overline{x_n} = x_n$. Okay. So this is because as X_n is real. So $\overline{x_n} = x_n$. So this question, this is equal to this, okay. Now, let us replace, let us consider X_n , this is valid for any k , okay. So let us consider $\overline{X_{n-k}}$, then k can be; here k varies from 0 to $N-1$, okay. k varies from 0 to $N-1$. Okay. So let us replace k by $N-k$ then, okay.

So $\overline{X_{N-k}}$ will be from here $\sum_{n=0}^{N-1} x_n e^{j2\pi (N-k)n/N}$, we are replacing $N-k$, so $N-k \cdot n/N$. And we can write it into two parts. e to the power $2\pi n \cdot N/N$ and the other part is e to the power $-2\pi k \cdot n/N$, okay. So this N cancels with this. e to the power $2\pi n = 1$, e to the power $2\pi n = \cos 2\pi n + j \sin 2\pi n$, so this is equal to 1 because n is an integer. Okay. So we get, this is equal to 1, we get only this, okay. So we get $X_n e^{-j2\pi kn/N}$. So $\overline{X_{N-k}} = X_k$.

(Refer Slide Time: 50:18)

Example 7 cont...

In particular if $k = 0$, then $X_0 = \overline{X_N}$ but we know that the sequence $X_0, X_1, \dots, X_{N-1}, \dots$ is an N-periodic sequence so $X_N = X_0$ which means that $X_0 = \overline{X_0} \Rightarrow X_0$ is real. Similarly, for other values of k , we can show that X_k is real. Thus, we get a real DFT.

$$\begin{aligned} X_0 &= \overline{X_N} = \overline{X_0} \\ X_0 &= \overline{X_0} \end{aligned} \quad \begin{aligned} X_k &= \overline{X_{N-k}} \quad k=1, 2, \dots, N-1 \\ X_k &\text{ is real} \end{aligned}$$

Now let us put $k=0$ in this, okay let us put $k=0$, so what do we get $\overline{X_n} = X_n$. $\overline{X_0} = X_0$. Now we know that $X_0, X_1, X_2, \dots, X_{N-1}$ is an N periodic sequence, okay. So $X_N = X_0$, okay. $X_N = X_0$,

so what do we get, $X_0 = X_n^*$. $X_0 = X_n^*$ so and $X_n = X_0$ so $X_n^* = X_0$. Okay. We know that, we have found that $X_0 = X_n^*$ but because of n periodicity $X_n = X_0$ var. So combining this and this okay, we get $X_0 = X_n^* = X_0^*$, So $X_0 = X_0^*$ var.

So this means that X_0 is real, okay. Similarly, we can take $k=1,2,3$ and so on up to $n-1$ and show that $X_k = X_k^*$ for all var. So we can show for other values of K that X_k is real. Okay, so X_k is real. If, so if the input sequence is real the output is also real, so we get real DFT.

(Refer Slide Time: 51:48)

Linearity property

If $u = \{u_j\}_{j=0}^{N-1}$ and $v = \{v_j\}_{j=0}^{N-1}$ are sequences of complex numbers and a, b are complex constants, then

$$D[au + bv](k) = aD[u](k) + bD[v](k).$$

$$\begin{aligned} D[au + bv](k) &= \sum_{j=0}^{N-1} (au_j + bv_j) e^{-2\pi i j k / N} \\ &= a \sum_{j=0}^{N-1} u_j e^{-2\pi i j k / N} + b \sum_{j=0}^{N-1} v_j e^{-2\pi i j k / N} \\ &= a D[u](k) + b D[v](k) \end{aligned}$$

Okay. Now Linearity Property. If you $u = u_j$ $j=0$ to $N-1$; $v = v_j$ $j=0$ to $N-1$ are sequences of complex numbers and a, b are complex constants, then D of $au + bv$ $k = aD u k + bD v k$. Okay. So this we can easily show D of $au + bk$ by definition = $\sum_{j=0}^{N-1} au_j + b v_j, e$ raise to the power $-2\pi i j k / n$ okay. Now, since this is a finite summation I can write it as $a u_j + b v_j$, b breaks in two parts then take a and b common a times, a will be out so a times u_j here + b times okay so this is a times $D u k + b d v k$, okay.

So this discrete Fourier transform satisfies linearity condition. It satisfy linearity property.

Example 8

Let $u = \{\sin(ja)\}_{j=0}^{N-1}$, where a is any complex number and is not an integer multiple of π . Then

$$U_k = \sum_{j=0}^{N-1} \sin(ja) e^{-2\pi i j k / N}$$

$$= \frac{1}{2i} \left(\frac{1 - e^{iaN}}{1 - e^{ia - 2\pi i k / N}} \right) - \frac{1}{2i} \left(\frac{1 - e^{-iaN}}{1 - e^{-ia - 2\pi i k / N}} \right) \text{ as } e^{-2\pi i k} = 1.$$

$$U_k = \sum_{j=0}^{N-1} \left(\frac{e^{ija} - e^{-ija}}{2i} \right) e^{-2\pi i j k / N}$$

$$= \frac{1}{2i} \left[\sum_{j=0}^{N-1} e^{ija} e^{-2\pi i j k / N} - \sum_{j=0}^{N-1} e^{-ija} e^{-2\pi i j k / N} \right] = \frac{1}{2i} \left[\sum_{j=0}^{N-1} (e^{ia - 2\pi i k / N})^j - \sum_{j=0}^{N-1} (e^{-ia - 2\pi i k / N})^j \right]$$

$\sin \theta = \frac{e^{i\theta} - e^{-i\theta}}{2i}$

Okay, now let consider this problem. $u = \sin ja$ $j=0$ to $N-1$ where a is any complex number and it is not an integer multiple of π . Okay, so then if you find the discrete Fourier transform of this sequence then U_k by definition will be equal to $\sum_{j=0}^{N-1} \sin ja e^{-2\pi i j k / N}$, okay. And let us put then the value of $\sin ja$. $\sin \theta$ we know, $\sin \theta = \frac{e^{i\theta} - e^{-i\theta}}{2i}$, okay. So $\sin ja$ we can put some values.

So $U_k = \sum_{j=0}^{N-1} \frac{e^{ija} - e^{-ija}}{2i} e^{-2\pi i j k / N}$, okay. So now let us use linearity property. So by linearity property we have $\frac{1}{2i}$ times $\sum_{j=0}^{N-1} e^{ija} e^{-2\pi i j k / N}$ and then $\sum_{j=0}^{N-1} e^{-ija} e^{-2\pi i j k / N}$ okay. Now we can write; let us find sum of this. So this is actually can be written as $\frac{1}{2i} \sum_{j=0}^{N-1} e^{ia} \sin j$; e to the power ia ; e to the power $-2\pi i k / N$ raise to the power j , okay.

And then similarly the other one, $\sum_{j=0}^{N-1} e^{-ia} e^{-2\pi i k / N}$ raise to the power j , okay. They are both geometric series, okay. So we can write it sum.

(Refer Slide Time: 56:06)

$$\begin{aligned}
&= \frac{1}{2L} \left[\sum_{j=0}^{N-1} \left(e^{ia - \frac{2\pi i k j}{N}} \right) - \sum_{j=0}^{N-1} \left(e^{-ia - \frac{2\pi i k j}{N}} \right) \right] \\
&= \frac{1}{2L} \left[\frac{1 - \left(e^{ia - \frac{2\pi i k}{N}} \right)^N}{1 - e^{ia - \frac{2\pi i k}{N}}} - \frac{1 - \left(e^{-ia - \frac{2\pi i k}{N}} \right)^N}{1 - e^{-ia - \frac{2\pi i k}{N}}} \right] \\
&= \frac{1}{2L} \left[\frac{1 - e^{iaN}}{1 - e^{ia - \frac{2\pi i k}{N}}} - \frac{1 - e^{-iaN}}{1 - e^{-ia - \frac{2\pi i k}{N}}} \right] \left(e^{-\frac{2\pi i k}{N}} \right)^N = 1
\end{aligned}$$

So we have, we have $1/2i$ sigma $j=0$ to $N-1$ e to the power $ia - 2\pi i k/n$, okay $2\pi i k/n$ raise to the power j , okay. So then we have this and then we have sigma - we have in the middle sigma $j=0$ to $N-1$ e to the power $-ia - 2\pi i k/n$ raise to the power j , okay. And we can write it sum $1/2i$, so this is geometric series. So $1 - e$ to the power $ia - 2\pi i k/n$ raise to the power n , okay divided by $1 - e$ to the power $ia - 2\pi i k$ divided by n , okay.

Here, we will have $1 - e$ raise to the power $-ia - 2\pi i k/n$ whole to the power n , divided by $1 - e$ to the power $-ia - 2\pi i k/n$, okay. Now this is nothing but $1/2i$, $1 - e$ to the power ian $1/1 - e$ to the power $ia - 2\pi i k/n$, okay. And then $-1 - e$ raise to the power $-ian/1 - e$ raise to the power $-ia - 2\pi i k/n$. This is because the e to the power $-2\pi i k/n$ raise to the power $n = 1$, okay. So this is what we get, okay as the answer to this problem, okay. Now; so with this I would like to end my lecture. Thank you very much for your attention.
