**Lecture - 42**  
**Basic Concepts of Probability**

Hello friends. Welcome to my lecture on basic concepts of probability. Modern probability theory is based on the axiomatic definition of probability. We define a probability model and state the axioms which any reasonable definition probability must satisfy. Let us consider a random experiment with the number of possible outcomes. The number of possible outcomes is either finite or infinite. Let  $N$  denote the number of possible outcomes

**Introduction**

Modern probability theory is based on the axiomatic definition of probability. We define a probability model and state the axioms which any reasonable definition of probability must satisfy.

Consider a random experiment with a number of possible outcomes. The number of possible outcomes is either finite or infinite. Let  $N$  denote the number of possible outcomes.

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 2

**(Refer Slide Time: 00:56)**

A presentation slide with a blue header bar. The main content area is white with a light blue background for the text. The footer is a dark blue bar with logos and a page number.

**Sample space**

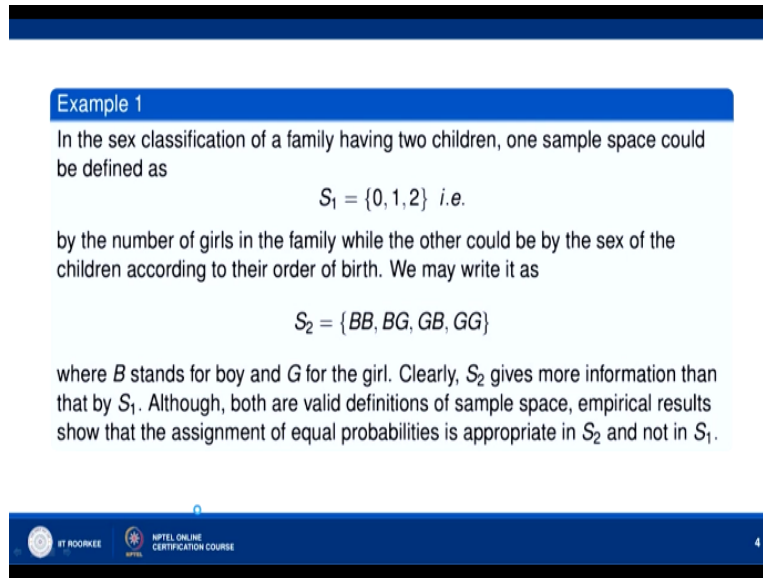

The set of all possible outcomes of a random experiment is called the sample space of the experiment. We denote it by  $S$ .

Each possible outcome is a member of  $S$  and is called a simple event. Thus the sample space is the set of all simple events. Simple events are also called sample points, elementary events etc.

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 3

The set of all possible outcomes of a random experiment is called the sample space of the experiment. We shall denote it by  $S$ . Each possible outcome is a member of  $S$  and is called a simple event. Thus, the sample space is the set of all simple events. Simple events are also called sample points or elementary events etc.

**(Refer Slide Time: 01:19)**

The slide is titled 'Example 1' in a blue header. The text describes two ways to define the sample space for a family with two children. The first way,  $S_1$ , is based on the number of girls (0, 1, 2). The second way,  $S_2$ , is based on the sex of the children in order of birth (BB, BG, GB, GG). The slide concludes that  $S_2$  provides more information than  $S_1$  and is more appropriate for assigning equal probabilities. The slide footer includes logos for IIT Roorkee and NPTEL, and the text 'NPTEL ONLINE CERTIFICATION COURSE' and the number '4'.

**Example 1**

In the sex classification of a family having two children, one sample space could be defined as

$$S_1 = \{0, 1, 2\} \text{ i.e.}$$

by the number of girls in the family while the other could be by the sex of the children according to their order of birth. We may write it as

$$S_2 = \{BB, BG, GB, GG\}$$

where  $B$  stands for boy and  $G$  for the girl. Clearly,  $S_2$  gives more information than that by  $S_1$ . Although, both are valid definitions of sample space, empirical results show that the assignment of equal probabilities is appropriate in  $S_2$  and not in  $S_1$ .

IIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 4

In the sex classification of a family having two children, one sample space could be defined as  $S_1$  = the set of elements 0, 1, 2 that is by the number of girls in the family while the other could be by the sex of the children according to their order of birth. We may write it as  $S_2$  = the set consisting BB, BG, GB, GG where B stands for boy and G for the girl. Clearly,  $S_2$  gives more information than that by  $S_1$ .

Although, both are valid definitions of sample space, empirical results show that the assignment of equal probabilities is appropriate in  $S_2$  and not in  $S_1$ .

**(Refer Slide Time: 02:05)**

### Example 2

Suppose customers arrive in a random fashion during a time interval of  $t$  units to be served at a counter. Then the sample space consists of  $\{0, 1, 2, \dots\}$ . Each simple event represents the number of customers arriving in the interval of  $t$  units. Though, in practice, there is a finite upper bound on the number of customers arriving in a specified time interval, it is convenient to write the sample space such that it has an infinite number of points.

Suppose customers arrive in a random fashion during a time interval of  $t$  units to be served at a counter. Then, the sample space consists of 0, 1, 2 and so on. Each simple event represents the number of customers arriving in the interval of  $t$  units. Though, in practice, there is a finite upper bound on the number of customers arriving in a specified time interval, it is convenient to write the sample space such that it has an infinite number of points.

**(Refer Slide Time: 02:43)**

### Events and relations among events

A compound event or simply 'event' is a collection of simple events. Thus, an event is a subset of the sample space  $S$ . We say that an event 'A occurs' or 'A happens' if any of the simple events constituting A occurs or happens.

A compound event or simply event is a collection of simple events. Thus, an event is a subset of the sample space  $S$ . We say that an event A occurs or A happens if any one of the simple events constituting A occurs or happens.

**(Refer Slide Time: 02:57)**

### Example 3

Suppose that 100 people in a region are classified not only as potential buyers and non-buyers of a particular brand of soap but also as males or females. Then a sample point may be characterized by four integers  $(M_b, F_b, M_n, F_n)$  giving in order the no. of male and female buyers, male and female non-buyers.

Here

$$M_b + F_b + M_n + F_n = 100$$

and sample point gives a possible combination.

Suppose that 100 people in a region are classified not only as potential buyers and non-buyers of a particular brand of soap but also as males or females. Then, a sample point may be characterized by 4 integers  $M_b, F_b, M_n, F_n$  giving in order the number of male and female buyers, male and female non-buyers. Here  $M_b + F_b + M_n + F_n = 100$  and sample point gives a possible combination.

(Refer Slide Time: 03:30)

### Cont...

The event "relatively more females buy than do the males" is the collection of those simple events in which  $\frac{F_b}{F_n} > \frac{M_b}{M_n}$ .

The simple event  $(7, 72, 17, 4)$  is one such point. Thus this event, say

$$A = \left\{ (M_b, F_b, M_n, F_n) : \frac{F_b}{F_n} > \frac{M_b}{M_n} \right\}.$$

$$\begin{array}{l} F_b = 72 \quad M_n = 17 \\ F_n = 4 \quad M_b = 7 \end{array} \quad \begin{array}{l} \frac{F_b}{F_n} = \frac{72}{4} = 18 \\ \frac{M_b}{M_n} = \frac{7}{17} \end{array} \quad \text{clearly } 18 > \frac{7}{17}$$

The event relatively more females buy than do the males is the collection of those sample points in which  $F_b/F_n$  is  $> M_b/M_n$ .  $F_b/F_n$  gives the relative frequency of the female buyers, so  $F_b/F_n > M_b/M_n$ . The simple event 7, 72, 17, 4 is one such point because here the value of  $F_b=72$ ,  $F_n=4$ ,  $M_n=17$  and  $M_b=7$ . So you can see that  $F_b/F_n$  is  $=72/4=18$  while  $M_b/M_n$  is  $=7/17$  okay  $M_b$  is  $=7/M_n$ ,  $M_n$  is  $=17$ .

So clearly 18 is  $> 7/17$ . That is  $F_b/F_n$  is  $> M_b/M_n$  okay. So 7, 72, 17, 4 is a one such sample point.

(Refer Slide Time: 05:00)

Null event or Impossible event

The event that has no simple events is called the null event and is denoted by  $\phi$ .

Complementary event

The event  $A'$  that corresponds to the complement of the set  $A \subset S$  is called the complementary event of  $A$ . In particular,

$$S' = \phi.$$

NPTEL ONLINE  
CERTIFICATION COURSE

9

Now the event that has no simple events is called the null event okay and is denoted by  $\phi$ . It is also called impossible event. The event  $A$  that corresponds to the complement of the set  $A$  subset of  $S$  is called the complementary event of  $A$  and so in particular if  $S$  denotes the sample space, then  $S$  complement,  $S$  complement is  $= \phi$ .

(Refer Slide Time: 05:27)

Intersection of two events  $A$  and  $B$

The collection of simple events that are common to both  $A$  and  $B$ , is called the intersection of  $A$  and  $B$  and is denoted by  $A \cap B$  or  $AB$ .  
If the event  $AB$  occurs, it means that both  $A$  and  $B$  occur simultaneously.

Mutually exclusive events

Two events  $A$  and  $B$  are called mutually exclusive if

$$AB = \phi.$$

This means that  $A$  and  $B$  can not occur simultaneously. The occurrence of one of the events  $A$  and  $B$  precludes the occurrence of the other at the same time.

NPTEL ONLINE  
CERTIFICATION COURSE

10

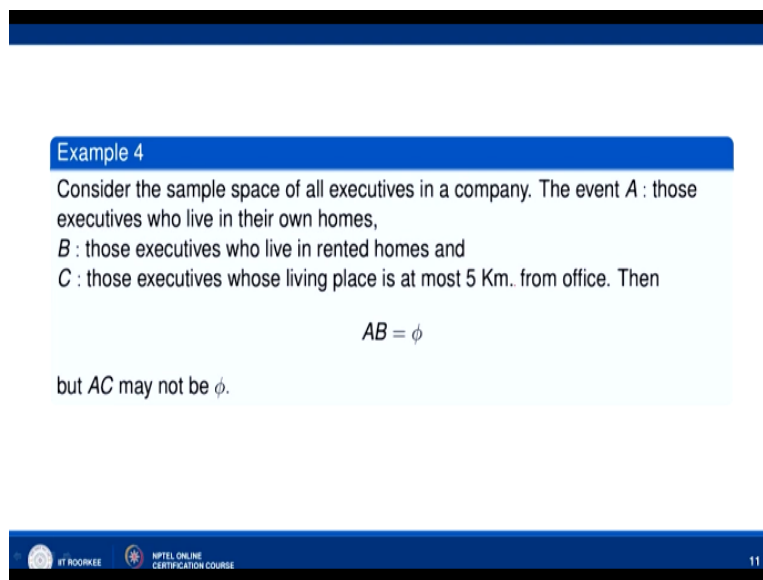

Now the collection of simple events that are common to both  $A$  and  $B$  is called the intersection of  $A$  and  $B$  and is denoted by  $A$  intersection  $B$  or we also denote it by  $AB$ . If the event  $AB$  occurs, it means that both  $A$  and  $B$  occur simultaneously. Two events  $A$  and  $B$  are

called mutually exclusive if  $A \cap B = \phi$ . This means that A and B cannot occur simultaneously okay.

Suppose you toss a coin okay, then if A is the event that the head appears and B is the event that the tail appears, then the event A and B are mutually exclusive. When you toss the coin either head will come or tail will come. If head comes tail cannot come, if tail comes head cannot come. So the two events A and B are mutually exclusive. So A and B cannot occur simultaneously.

The occurrence of one of the events A and B precludes the occurrence of the other at the same time.

**(Refer Slide Time: 06:28)**

The slide content is displayed within a white rectangular area with a blue border. At the top left of this area is a blue header with the text "Example 4" in white. Below the header, the text describes a sample space of executives and defines three events: A (own homes), B (rented homes), and C (within 5 km of office). It then states that the intersection of A and B is an empty set, while the intersection of A and C is not necessarily empty. At the bottom of the slide, there is a blue footer bar containing logos for IIT Roorkee and NPTEL, along with the text "NPTEL ONLINE CERTIFICATION COURSE" and the slide number "11".

**Example 4**

Consider the sample space of all executives in a company. The event A : those executives who live in their own homes,  
B : those executives who live in rented homes and  
C : those executives whose living place is at most 5 Km. from office. Then

$$AB = \phi$$

but AC may not be  $\phi$ .

IIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 11

Consider the sample space of all executives in a company. The event A is the event that those executives who live in their own homes okay. A is the event that those executives who live in their own homes, B is the event of those executives who live in rented homes and C denotes the event that those executives whose living space is at most 5 kilometers from office okay. Then, A intersection B okay.

A is the event those executives who live in their own homes and B is the event those executives who live in rented homes. So A intersection B is  $\phi$  but A intersection C may not be  $\phi$  because A is the event that those executives who live in their own homes and C is the event those executives whose living space is at most 5 kilometers from office. So there may

be some executives whose living space is at most 5 kilometers from office and they live in their own homes okay. So  $A \subset B$  may not be  $\phi$ .

(Refer Slide Time: 07:32)

Union of two events

Let  $A$  and  $B$  be any two events. If either  $A$  or  $B$  or both occur, we say that  $A \cup B$  occurs and we denote it by

$$A \cup B.$$

Suppose the occurrence of an event  $A$  implies the occurrence of another event  $B$ . Then we write

$$A \subset B.$$

NPTEL ONLINE CERTIFICATION COURSE
12

Now let us consider the union of two events. Let  $A$  and  $B$  be any two events. If either  $A$  or  $B$  or both occur, we say that  $A$  union  $B$  occurs and we denote it by  $A$  union  $B$ . Suppose the occurrence of an event  $A$  implies the occurrence of another event  $B$ . Then, we say that  $A$  is subset of  $B$ .

(Refer Slide Time: 07:53)

$\sigma$ -field

Let  $S$  be the sample space associated with a random experiment  $E$ . Then, a  $\sigma$ -field is a non empty class  $\mathbf{B}$  of subsets of  $S$  that is closed under the formation of countable union and complementations i.e.  $\mathbf{B}$  satisfies the following conditions

(i)  $A_1, A_2, A_3, \dots, A_n, \dots \in \mathbf{B} \Rightarrow \bigcup_{i=1}^{\infty} A_i \in \mathbf{B}$  if  $A_1, A_2, \dots \in \mathbf{B} \Rightarrow A_1, A_2, \dots, A_n, \dots \in \mathbf{B}$

(ii)  $A \in \mathbf{B} \Rightarrow A' \in \mathbf{B}$  if  $A \in \mathbf{B} \Rightarrow A' \in \mathbf{B}$   
 $\Rightarrow A \cap B' \in \mathbf{B}$  or  $A - B \in \mathbf{B}$

Basic properties of  $\sigma$ -field

**Lemma:** If  $\mathbf{B}$  is a  $\sigma$ -field, then following properties holds; if  $A \in \mathbf{B}$  then  $A' \in \mathbf{B}$   
so  $A \in \mathbf{B}, A' \in \mathbf{B} \Rightarrow A \cup A' \in \mathbf{B} \Rightarrow S \in \mathbf{B}$

(a)  $\phi, S \in \mathbf{B}$ .

(b)  $A_1, A_2, A_3, \dots, A_n, \dots \in \mathbf{B} \Rightarrow \bigcap_{i=1}^{\infty} A_i \in \mathbf{B}$  if  $S \in \mathbf{B}$  then  $S' \in \mathbf{B} \Rightarrow A \cup A' \in \mathbf{B} \Rightarrow S \in \mathbf{B}$

(c)  $A, B \in \mathbf{B} \Rightarrow A - B \in \mathbf{B}$  since  $(A \cup B)' = A' \cap B'$  it follows that  $\mathbf{B}$  is closed under the countable intersection with sections

NPTEL ONLINE CERTIFICATION COURSE
13

Now let us define the sigma field. Let  $S$  be the sample space associated with a random experiment  $E$ . Then, a sigma field is a nonempty class  $\mathbf{B}$  of subsets of  $S$  that is closed under the formation of countable unions and complementations. That is the set  $\mathbf{B}$ , class  $\mathbf{B}$  satisfies

the following conditions. If  $A_1, A_2, A_3, A_n$  and so on are the sets belonging to the class  $B$ , then they are countable union.

Union  $i=1$  to infinity  $A_i$  also belongs to  $B$  and if  $A$  belongs to  $B$  then its complement,  $A^c$  also belongs to  $B$ . Now from these definitions of sigma field, we can drive the basic properties of sigma field. If  $B$  is a sigma field, then following properties holds okay,  $\phi$  and  $S$  belong to  $B$ . So let us first show the part a of the lemma. We have to show that  $\phi, S$  belongs to  $B$ .

So from the condition 2 from this condition okay if  $A$  belongs to  $B$  then  $A^c$  complement belongs to  $B$  okay. So since  $B$  is a nonempty set okay, nonempty class okay, so there must be some set at least there in  $B$ , so let us say the set is  $A$ . So if  $A$  belongs to  $B$  then its complement also belongs to  $B$ . So  $A$  belongs to  $B$ ,  $A^c$  complement belongs to  $B$  implies that  $A \cup A^c$  belongs to  $B$  okay.

$A \cup A^c$  is  $S$  okay, so this implies that  $S$  belongs to  $B$  okay. Now if  $S$  belongs to  $B$ , then  $S^c$  complement also belongs to  $B$  okay. If  $S$  belongs to  $B$ , then  $S^c$  complement also belongs to  $B$ .  $S^c$  complement means that is  $\phi$  belongs to  $B$  because  $S$  is the whole space okay. Now  $A_1, A_2, A_n$  belongs to  $B$  implies that intersection  $i=1$  to infinity  $A_i$  belongs to  $B$  that means  $B$  is closed under the formation of countable intersections okay.

So this we can prove as  $A_1, A_2$  and so on  $A_n$  belongs to  $B$  implies that their complements belong to  $B$  okay. Now  $B$  is closed under the formation of countable unions, so union  $i=1$  to infinity  $A_i^c$  complement belongs to  $B$  okay by this property. Now this implies that by second property that if  $A$  belongs to  $B$ ,  $A^c$  complement belongs to  $B$ . So union  $A_i$   $i=1$  to infinity complement okay complement of this belongs to  $B$ .

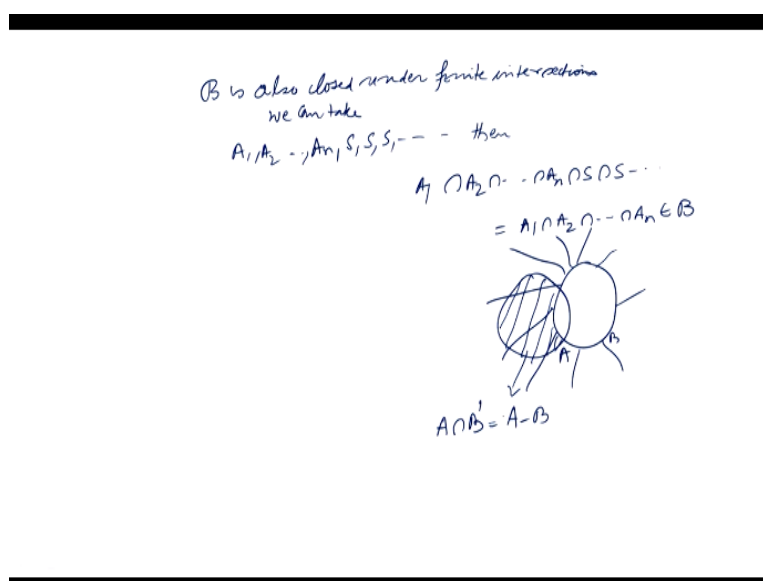

By De Morgan's law, union  $A_i^c$  is  $=$  intersection  $A_i$  okay. Now  $A^c$  complement complement is  $A$  okay, so this is intersection  $i=1$  to infinity  $A_i$  okay belongs to  $B$  okay. So that is to say since intersection  $A_i^c$  complement complement is  $=$  intersection  $A_i$   $i=1$  to infinity okay. It follows that  $B$  is closed under the formation of countable intersections okay.

Now if  $A \in B$  then  $A \cap B = A$  belongs to  $B$  okay. So  $A \in B$  implies that  $A \cap B$  belongs to  $B$  okay and  $A \cap B^c$  belongs to  $B$  means by this property that the class  $B$  is closed under the formation of countable intersections. From here, we can say that  $A \cap B^c$  belongs to  $B$  okay.  $A \cap B^c$  is  $A - B$  or now here you may say that this is countable intersection, how we can say about finite intersection?

We can take say  $A_1, A_2, A_3$  and so on  $A_n$  belong to  $B$ . So you can take say finite number of them and rest you can take as  $S$  okay.

(Refer Slide Time: 13:19)

If  $B$  is also closed under finite intersections, we can take  $A_1, A_2$  and so on  $A_n$  finite number of them  $S \cap A_{n+1}$  as we can as  $S \cap A_{n+2}$  we can take as and so on. Then, intersection  $A_1$  intersection  $A_2$  intersection  $A_n$  intersection  $S$  intersection  $S_n$  so on. This will be  $A_1$  intersection  $A_2$  intersection  $A_n$ . So  $B$  is also closed under the formation of finite intersections okay. So using this property, we can say that when  $A$  and  $B$  belong to  $B$  then by second condition  $A \cap B^c$  belongs to  $B$  and so  $A \cap B^c$  belongs to  $B$ .

But  $A \cap B^c$  is  $A - B$ . We can see from here. Suppose this is our  $A$ , this is  $B$  okay, then so  $A \cap B^c$  okay.  $B^c$  is this complement of  $B$  okay. This is  $B^c$  and clearly  $B^c \cap A$ ,  $A \cap B^c$  is this which is nothing but  $A - B$  okay. So  $A \cap B^c$  is  $A - B$  okay. So this is how we prove these properties of the sigma field.

(Refer Slide Time: 15:22)

#### Definition of probability

Suppose we have sample space  $S$ . If  $S$  is discrete, all subsets correspond to events and conversely, but if  $S$  is nondiscrete, only special subsets (called measurable) correspond to events. To each event  $A$  in the class  $C$  of events, we associate a real number  $P(A)$ . Then  $P$  is called a *probability function*, and  $P(A)$  the *probability* of the event  $A$ , if the following axioms are satisfied.

Now let us go to definition of probability. Suppose we have a sample space  $S$ . If  $S$  is discrete, all subsets correspond to events and conversely and if  $S$  is nondiscrete, only special subsets called measurable correspond to events. To each event  $A$  in the class  $C$  of events, so let us consider class  $C$  of events.  $C$  is actually sigma field here, the sigma field which we have defined just now that we are taking as  $C$  here.

So  $C$  is the sigma field, so to each event  $A$  in the class  $C$  of events, we associate a real number  $P(A)$  okay. So you take any event belonging to the class  $C$  associate a real number  $P(A)$  with that then  $P$  will be called probability function and  $P(A)$  the probability of the event  $A$  if the following axioms are satisfied.

(Refer Slide Time: 16:12)

#### Cont...

**Axiom 1:** For every event  $A$  in the class  $C$ ,

$$P(A) \geq 0$$

**Axiom 2:** For the sure or certain event  $S$  in the class  $C$ ,

$$P(S) = 1$$

**Axiom 3:** For any number of mutually exclusive events  $A_1, A_2, \dots$ , in the class  $C$ ,

$$P(A_1 \cup A_2 \cup \dots) = P(A_1) + P(A_2) + \dots$$

In particular, for two mutually exclusive events  $A_1, A_2$ ,

$$P(A_1 \cup A_2) = P(A_1) + P(A_2)$$

First axiom is that for every event  $A$  in the class  $C$ , we must have  $P(A) \geq 0$  okay. So the second one is for the sure or certain event  $S$  okay,  $S$  is the whole space so it is sure to happen, so for the sure or certain event  $S$  in the class  $C$ ,  $P(S)$  must be  $=1$ . For any number of mutually exclusive events  $A_1, A_2$  and so on in the class  $C$ ,  $P(A_1 \cup A_2 \text{ and so on}) = P(A_1) + P(A_2) \text{ and so on}$ .

In particular, for two mutually exclusive events,  $A_1, A_2$   $P(A_1 \cup A_2) = P(A_1) + P(A_2)$ . So we will say that  $P$  is the probability function provided these conditions are satisfied.

(Refer Slide Time: 17:03)

Some Important Theorems on Probability

**Theorem 1:** If  $A_1 \subset A_2$ , then

$$P(A_1) \leq P(A_2)$$

and

$$P(A_2 - A_1) = P(A_2) - P(A_1).$$

*Handwritten notes:*

$A_2 = A_1 \cup (A_2 - A_1)$ , where  $A_1 \cap (A_2 - A_1) = \phi$

So  $P(A_2) = P(A_1 \cup (A_2 - A_1))$

$= P(A_1) + P(A_2 - A_1)$

$\Rightarrow P(A_2) \geq P(A_1)$  because  $P(A_2 - A_1) \geq 0$  Hence the prob function is monotone

16

Now let us look at some important theorems on probability. If  $A_1$  and  $A_2$  are any two events belonging to the class  $C$  of events and  $A_1$  is subset of  $A_2$ , then  $P(A_1) \leq P(A_2)$ . So let us see, by Venn diagram we can say this is say  $A_1$  and this is say  $A_2$  okay. So  $A_1$  is contained in  $A_2$  okay  $A_1$  is contained in  $A_2$ , so we can say that  $A_2$  is  $= A_1 \cup A_2 - A_1$  or you can put a union here okay  $A_2 = A_1 \cup A_2 - A_1$  okay.

Moreover, that  $A_1$  and  $A_2 - A_1$  are mutually exclusive because their intersection is  $\phi$  okay where  $A_1 \cap A_2 - A_1 = \phi$ . So probability of  $A_2$  will be  $=$  probability of  $A_1 \cup A_2 - A_1$  okay. Since  $A_1 \cap A_2 - A_1$  is  $\phi$ , we have  $P(A_1) + P(A_2 - A_1)$  okay. Let us go to this condition axiom 3,  $P(A_1 \cup A_2) = P(A_1) + P(A_2)$  if  $A_1 \cap A_2$  is  $\phi$  okay. So here and you see that  $A_1, A_2$  are events, so  $A_2 - A_1$  is also an event okay belonging to the class  $C$ .

And therefore  $P(A_2 - A_1) \geq 0$  okay, so  $P(A_2) \geq P(A_1)$  because  $P(A_2 - A_1) \geq 0$ . So if  $A_1$  is subset of  $A_2$  then  $P(A_1) \leq P(A_2)$ . So we can say that the probability function is monotone okay. It satisfies the monotone property.

(Refer Slide Time: 19:42)

**Theorem 2**

For every event  $A$ ,

$$0 \leq P(A) \leq 1,$$

i.e. a probability is between 0 and 1.

Since  $A \subset S$  so  
 $P(A) \leq P(S) = 1$   
 then  $0 \leq P(A) \leq 1$

NPTEL ONLINE CERTIFICATION COURSE
17

Now for every event  $A$   $0 \leq P(A) \leq P(S)$  okay since  $A$  is subset of  $S$ . You take any event  $A$  belonging to the class  $C$  of events, then  $A$  is subset of  $S$ . So  $P(A) \leq P(S)$  okay and  $P(S) = 1$  okay. This we have already assumed  $P(S) = 1$  in the axiom 2, so you take any event  $A$  subset of  $S$  then  $P(A) \leq P(S)$  and therefore  $0 \leq P(A) \leq 1$  okay because you take any event  $A$  belonging to the class  $C$  of events  $P(A) \geq 0$  okay so  $0 \leq P(A) \leq 1$ .

(Refer Slide Time: 20:37)

**Theorem 3**

$P(\phi) = 0$

i.e. the impossible event has probability zero.

Let  $A \in C$   
 then  $A \cup \phi = A$   
 $P(A \cup \phi) = P(A)$   
 $P(A) + P(\phi) = P(A)$ , because  $A \cap \phi = \phi$   
 $\Rightarrow P(\phi) = 0$

NPTEL ONLINE CERTIFICATION COURSE
18

Now probability of  $\phi$  is  $= 0$  okay. So let us prove this. Let  $A$  be any event belonging to the class  $C$  okay. Then,  $A \cup \phi = A$  okay. Since  $A$  and  $\phi$  are mutually exclusive,  $P(A \cup \phi) = P(A) + P(\phi)$  okay. So  $P(A) + P(\phi) = P(A)$  okay. So  $P(\phi) = 0$  okay.

$P(A \cap \phi) = P(A) \cap P(\phi) = 0$ . This is because  $A$  and  $\phi$  are mutually exclusive. So then this implies that  $P(\phi) = 0$  because we can cancel  $P(A)$  both sides,  $P(A)$  is line between 0 and 1, so we can cancel and therefore  $P(\phi) = 0$ .

(Refer Slide Time: 21:36)

Theorem 4

If  $A'$  is the complement of  $A$ , then

$$P(A') = 1 - P(A)$$

*We know that  $A \cup A' = S$   
 $P(A \cup A') = P(S) = 1$   
 Since  $A \cap A' = \phi$   
 $P(A) + P(A') = 1$   
 $\Rightarrow P(A') = 1 - P(A)$*

NPTEL ONLINE CERTIFICATION COURSE
19

Now let us say prove  $P(A') = 1 - P(A)$ . So we know that  $A \cup A' = S$  okay. Then,  $P(A \cup A') = P(S) = 1$  okay. Since  $A$  and  $A'$  are mutually exclusive. So  $P(A) + P(A')$  we shall get okay.  $P(A \cup A')$  will give us  $P(A) + P(A')$  this is 1. This implies that  $P(A') = 1 - P(A)$ . So probability of the complement of  $A$  is  $1 - P(A)$ .

(Refer Slide Time: 22:31)

Theorem 5

If  $A = A_1 \cup A_2 \cup \dots \cup A_n$ , where  $A_1, A_2, \dots, A_n$  are mutually exclusive events, then

$$P(A) = P(A_1) + P(A_2) + \dots + P(A_n)$$

In particular, if  $A = S$ , the sample space, then

$$P(A_1) + P(A_2) + \dots + P(A_n) = 1$$

NPTEL ONLINE CERTIFICATION COURSE
20

Now let us come to if  $A = A_1 \cup A_2$  and so on  $A_n$  where  $A_1, A_2, A_n$  are mutually exclusive events, then  $P(A) = P(A_1) + P(A_2) + \dots + P(A_n)$ . In particular, if  $A = S$  the sample space, then  $P(A_1) + P(A_2) + \dots + P(A_n) = 1$  okay. So we have this axiom here  $P(A_1 \cup A_2) = P(A_1) + P(A_2)$  okay. So in

particular for two mutually in case of two mutually exclusive events,  $P(A_1 \cup A_2) = P(A_1) + P(A_2)$ . This we can by mathematical induction, from here we can say that  $P(A_1 \cup A_2 \cup \dots \cup A_n) = P(A_1) + P(A_2) + \dots + P(A_n)$ .

If  $A=S$  then  $P(S)$  will be  $P(A_1) + P(A_2) + \dots + P(A_n)$  so  $P(S)=1$  therefore  $P(A_1) + P(A_2) + \dots + P(A_n)=1$ . Now here how we get in particular for two mutually exclusive events, this gives us  $P(A_1) + P(A_2)$  okay. So this can be shown once you have  $P(\phi)=0$  okay. So we can take after  $A_1, A_2, A_3, A_4, A_5, A_6$  all we can take as  $\phi$ , then  $P(A_1 \cup A_2 \cup \phi \cup \phi \cup \phi \cup \phi)$  and so on will give us  $P(A_1 \cup A_2)$  and  $P(\phi)=0$ , so we will get  $P(A_1) + P(A_2)$ , so this comes from that.

We can take  $A_3, A_4, A_5, A_6$  all as  $\phi$  and then  $P(A_1 \cup A_2 \cup \phi \cup \phi \cup \phi \cup \phi)$  gives  $P(A_1 \cup A_2)$  and we get here  $P(A_1) + P(A_2)$  because of the fact that  $P(\phi)=0$ .

(Refer Slide Time: 24:21)

**Theorem 6**  
If  $A$  and  $B$  are any two events, then

$$P(A \cup B) = P(A) + P(B) - P(A \cap B)$$

*✓ Addition theorem if prob*

More generally, if  $A_1, A_2, A_3$  are any three events, then

$$P(A_1 \cup A_2 \cup A_3) = P(A_1) + P(A_2) + P(A_3) - P(A_1 \cap A_2) - P(A_2 \cap A_3) - P(A_3 \cap A_1) + P(A_1 \cap A_2 \cap A_3)$$

Generalizations to  $n$  events can also be made.

*Handwritten notes:*  
 $A \cup B = (A - B) \cup B$   
 $P(A \cup B) = P(A - B) + P(B)$  because  $(A - B) \cap B = \phi$   
 $= P(A) - P(A \cap B) + P(B)$   
 $A = (A - B) \cup (A \cap B)$   
 $P(A) = P(A - B) + P(A \cap B)$

So if  $A$  and  $B$  are any two events, then  $P(A \cup B) = P(A) + P(B) - P(A \cap B)$  okay. So let us prove this. We have suppose we have this is our set  $A$ , this is another set  $B$  okay. Then,  $A \cup B$  can be written as  $A - B$ , this is  $A - B$ ,  $A - B + B$  okay, so  $A - B \cup B$  okay. So probability  $A \cup B =$  probability of  $A - B +$  probability of  $B$  because  $A - B \cap B = \phi$  because  $A - B \cap B = \phi$  okay.

So now  $A - B$ ,  $A - B \cap A = \phi$  is  $A - B \cup A \cap B$ . This is  $A \cap B$ , so  $A = A - B \cup A \cap B$  and therefore  $P(A) = P(A - B) + P(A \cap B)$  because  $A - B$  and  $A \cap B$  are mutually exclusive. So this gives us  $P(A - B) = P(A) - P(A \cap B)$ . So this

is  $= P(A) - P(A \cap B) + P(B)$  okay. So  $P(A \cup B) = P(A) + P(B) - P(A \cap B)$ . This is also called the addition theorem of probability okay.

More generally if  $A_1, A_2, A_3$  are any 3 events, then  $P(A_1 \cup A_2 \cup A_3)$  is  $= P(A_1) + P(A_2) + P(A_3) - P(A_1 \cap A_2) - P(A_2 \cap A_3) - P(A_3 \cap A_1) + P(A_1 \cap A_2 \cap A_3)$ . Let us prove this result because we shall need it later on.

(Refer Slide Time: 26:52)

$$\begin{aligned}
 & P(A_1 \cup A_2 \cup A_3) \\
 &= P(A_1 \cup B) \\
 &= P(A_1) + P(B) - P(A_1 \cap B) \\
 &= P(A_1) + P(A_2 \cup A_3) - P(A_1 \cap (A_2 \cup A_3)) \\
 &= P(A_1) + P(A_2) + P(A_3) - P(A_2 \cap A_3) - P((A_1 \cap A_2) \cup (A_1 \cap A_3)) \\
 &= P(A_1) + P(A_2) + P(A_3) - P(A_2 \cap A_3) - [P(A_1 \cap A_2) + P(A_1 \cap A_3) - P((A_1 \cap A_2) \cap (A_1 \cap A_3))] \\
 &= P(A_1) + P(A_2) + P(A_3) - P(A_2 \cap A_3) - P(A_1 \cap A_2) - P(A_1 \cap A_3) + P(A_1 \cap A_2 \cap A_3)
 \end{aligned}$$

So we have  $P(A_1 \cup A_2 \cup A_3)$  okay. We can use the result for 2 events. So let us consider  $A_2 \cup A_3$  as  $B$ , let  $B = A_2 \cup A_3$ . So then we will have  $P(A_1 \cup B)$ . We have already proved that  $P(A \cup B) = P(A) + P(B) - P(A \cap B)$ . So let us apply that result. So we have  $P(A_1) + P(B) - P(A_1 \cap B)$ ,  $A_1$  is sorry  $B$  is  $A_2 \cup A_3$ , so  $P(A_1) + P(A_2 \cup A_3)$  we have and here we will have  $P(A_1 \cap A_2 \cup A_3)$  okay.

Now again the result  $P(A \cup B) = P(A) + P(B) - P(A \cap B)$ . We then write  $P(A_1) + P(A_2) + P(A_3) - P(A_2 \cap A_3) - P(A_1 \cap A_2) - P(A_1 \cap A_3) + P(A_1 \cap A_2 \cap A_3)$  and here this will be  $= P(A_1 \cap A_2 \cup A_3)$  will be  $A_1 \cap A_2 \cup A_3$  using the property of set theory union  $A_1 \cap A_2 \cup A_3$  okay. So this will be  $= P(A_1) + P(A_2) + P(A_3) - P(A_2 \cap A_3) - P(A_1 \cap A_2) - P(A_1 \cap A_3) + P(A_1 \cap A_2 \cap A_3)$ . Now we have one event here, one event here okay. So  $P(A_1 \cap A_2) + P(A_1 \cap A_3) - P(A_1 \cap A_2 \cap A_3)$  is  $A_1 \cap A_2 \cup A_3$  okay.

So this gives us  $P(A_1) + P(A_2) + P(A_3) - P(A_2 \cap A_3) - P(A_1 \cap A_2) - P(A_1 \cap A_3) + P(A_1 \cap A_2 \cap A_3)$ . Now  $A_1 \cap A_2 \cap A_3$  is  $A_1 \cap A_2 \cap A_3$ .

intersection  $A \cap B$  okay. So this is how we prove the result in case of 3 events okay. So generalizations to  $n$  events can be then similarly.

(Refer Slide Time: 29:56)

**Theorem 7**

For any events  $A$  and  $B$ ,

$$P(A) = P(A \cap B) + P(A \cap B')$$

$$\begin{aligned}
 A &= A \cap S \\
 &= A \cap (B \cup B') \\
 &= (A \cap B) \cup (A \cap B') \\
 \Rightarrow P(A) &= P(A \cap B) + P(A \cap B')
 \end{aligned}$$

$$\begin{aligned}
 (A \cap B) \cap (A \cap B') &= A \cap B \cap B' \\
 &= A \cap \emptyset = \emptyset
 \end{aligned}$$

 NPTEL ONLINE  
CERTIFICATION COURSE
 
22

Now for any events  $A$  and  $B$ ,  $P(A) = P(A \cap B) + P(A \cap B')$  okay. So let us prove this. We can say  $A = A \cap S$  okay,  $S$  is the sample space okay and this I can write as  $A \cap (B \cup B')$  okay,  $B$  is any other event, so  $B \cup B' = S$ . Now this is  $(A \cap B) \cup (A \cap B')$  okay. Now  $(A \cap B) \cap (A \cap B') = \emptyset$  okay.

$(A \cap B) \cap (A \cap B') = A \cap B \cap B'$ ,  $B \cap B' = \emptyset$ , so we have  $A \cap \emptyset$ , so this is  $\emptyset$  and therefore probability of  $A = P(A \cap B) + P(A \cap B')$  okay.

(Refer Slide Time: 31:08)

### Theorem 8

If an event  $A$  must result in the occurrence of one of the mutually exclusive events  $A_1, A_2, \dots, A_n$ , then

$$P(A) = P(A \cap A_1) + P(A \cap A_2) + \dots + P(A \cap A_n)$$

$$\begin{aligned} A &= A \cap \bigcup_{i=1}^n A_i \\ &= (A \cap A_1) \cup (A \cap A_2) \cup \dots \cup (A \cap A_n) \\ P(A) &= P(A \cap A_1) + P(A \cap A_2) + \dots + P(A \cap A_n) \end{aligned}$$

$A_i \cap A_j = \emptyset, i \neq j, i, j = 1, 2, \dots, n$

Now if an event  $A$  must result in the occurrence of one of the mutually exclusive events  $A_1, A_2, A_3$  and so on  $A_n$  okay. If an event  $A$  must result in the occurrence of one of the mutually exclusive events  $A_1, A_2, A_3$  and so on, then we shall have  $A = A \cap A_1 \cup A \cap A_2 \cup A \cap A_3$  and so on, so we can say  $A \cap \bigcup_{i=1}^n A_i$  okay. If we take the intersection of  $A$  with  $i=1$  to  $n$  union  $A_i$ , then it will be  $A$ .

So this will be  $A \cap A_1 \cup A \cap A_2 \cup A \cap A_3 \cup \dots \cup A \cap A_n$ . If an event  $A$  must result in the occurrence of one of the mutually exclusive events.  $A_1, A_2, A_n$  are mutually exclusive means  $A_i \cap A_j = \emptyset$  whenever  $i$  is not equal to  $j$  and  $i, j$  vary from 1 to  $n$  okay. So this gives you  $P(A) = P(A \cap A_1) + P(A \cap A_2) + P(A \cap A_3) + \dots + P(A \cap A_n)$  because they are also mutually exclusive because their intersection is  $\emptyset$ .

So probability of  $A \cap A_1$  + probability of  $A \cap A_2$  and so on probability of  $A \cap A_n$  because they are mutually exclusive.

**(Refer Slide Time: 33:04)**

### Example 5

Given an experiment such that

$$P(A) = \frac{1}{2}, P(B) = \frac{1}{3}, P(A \cap B) = \frac{1}{4}. \text{ Compute}$$

(i)  $P(A' \cap B')$  (ii)  $P(A' \cap B)$ .

$$P(A' \cap B') = P((A \cup B)') = 1 - P(A \cup B) = 1 - \frac{7}{12} = \frac{5}{12}$$

$$\begin{aligned} P(A \cup B) &= P(A) + P(B) - P(A \cap B) \\ &= \frac{1}{2} + \frac{1}{3} - \frac{1}{4} = \frac{6+4-3}{12} = \frac{7}{12} \end{aligned}$$

$$P(A' \cap B) = P(B - A) = P(B) - P(A \cap B) = \frac{1}{3} - \frac{1}{4} = \frac{1}{12}$$

Now let us take some exercises. So we are given a random experiment where A and B are any two events. So probability of A is  $1/2$ , probability of B is  $1/3$  and we are given that probability of A intersection B is  $1/4$ . We have to compute the probability of A complement intersection B complement. Now probability of A complement intersection B complement is = probability of A union B complement.

A union B complement is A complement intersection B complement and probability of A dash we know probability of A dash is  $1 - \text{probability of A}$ . So this is  $1 - \text{probability of A union B}$  okay. Now probability of A union B we know, probability of A union B is = probability of A + probability of B - probability of A intersection B by addition theorem of probability. So  $P(A) = 1/2$ ,  $P(B) = 1/3$  and  $P(A \cap B) = 1/4$ , so this is how much it is?

This will be  $12$ , so this is  $6$  here and here we have  $4$  and here we have  $3$  okay. So  $6, 4, 3$  and we shall have it  $7/12$  okay. So  $1 - 7/12$  gives you  $5/12$ . So  $P(A' \cap B')$  is  $5/12$ . Now probability of A dash intersection B okay, so let us see we have A here, this is A, this is B okay. So A dash is this one sorry A dash is this is A dash okay, this is A dash, so A dash intersection B will be B - A okay.

So this is probability of B - A okay. Probability of B - A we have to find okay, so from B we have to subtract A intersection B, this is A intersection B okay. So this is = probability of B - probability of A intersection B and probability of B is  $1/3$  and this is  $1/4$ . So we get  $1/12$  okay.

(Refer Slide Time: 35:45)

#### Example 6

In a city, three English dailies A, B and C are published, and a recent survey of readers indicates the following:

30% read A, 20% read B, 15% read C, 10% read both A and B, 8% read both B and C, 4% read A and C and 2% read A, B and C. Compute the probability that at least one paper among A, B and C is read by a randomly chosen person in the city.

$$\begin{aligned}P(A) &= .3, P(B) = .2, P(C) = .15, P(A \cap B) = .10, P(B \cap C) = .08 \\P(A \cap C) &= .04, P(A \cap B \cap C) = .02 \\P(A \cup B \cup C) &= P(A) + P(B) + P(C) - P(A \cap B) - P(B \cap C) - P(A \cap C) + P(A \cap B \cap C) \\&= .3 + .2 + .15 - .10 - .08 - .04 + .02 \\&= .65 - .22 + .02 = .45\end{aligned}$$

So now let us now go to next question. In a city, three English dailies A, B and C are published and a recent survey of readers indicates the following. A people read 30%, 30% people read A paper okay, so probability of the paper A is=30% that is 3.3. The paper B is read by 20% people, so probability of B is=0.2. C paper is read by 15%, so probability of C is 0.15 okay, 10% people read both A and B.

So probability of A intersection B is=0.10, 8% read both B and C, so B intersection C probability of B intersection C is=8% that is 0.08 okay. Probability of A intersection C okay 4% that is 0.04 okay. Now 2% people read A, B and C, so probability of A intersection B intersection C is=0.02 okay. Now compute the probability that at least one paper among A, B and C is read by a randomly chosen person in the city.

So we need the probability of A union B union C okay and we have done this formula. This is probability of A+probability of B+probability of C-probability of A intersection B-probability B intersection C-probability of A intersection C+probability of A intersection B intersection C okay. So  $P_A=0.3$   $P_B=0.2$   $P_C=0.15$ , probability of A intersection B is 0.10, probability of B intersection C is 0.08, probability of A intersection C is 0.04+probability of A intersection B intersection C is 0.02 okay.

So let us calculate this. So  $0.30+0.20$  is  $0.50+0.15$ , this is 0.65 okay and here we have 0.10, 0.08 so 0.18 and then 0.04 is 0.22 and here we have 0.02. So how much we get?  $0.65+0.02$  is 0.67, so  $0.67-0.22$  is 0.45. That means 45% people okay read at least one of the 3 papers at A, B or C okay.

(Refer Slide Time: 38:49)

**Example 7**

Find  $P(A \text{ XOR } B)$ , where  $P(A \text{ XOR } B)$  is the event that either A or B but not both will happen. Here XOR means exclusive OR function.

**Solution:** Clearly,  
 $A \text{ XOR } B = (A-B) \cup (B-A)$   
 $\Rightarrow P(A \text{ XOR } B) = P(A) - P(A \cap B) + P(B) - P(A \cap B)$   
 $= P(A) + P(B) - 2P(A \cap B)$

Handwritten notes and diagram:

$(A-B) \cap (B-A) = \phi$   
 So  
 $P(A \text{ XOR } B) = P(A-B) + P(B-A)$   
 $= P(A) + P(B) - 2P(A \cap B)$

Diagram: A Venn diagram with two overlapping circles, A and B. The region A-B is shaded with diagonal lines, and the region B-A is shaded with horizontal lines. The intersection A ∩ B is unshaded.

Handwritten equations for probabilities of regions:

$$P(A) = P(A-B) + P(A \cap B)$$

$$P(B) = P(B-A) + P(A \cap B)$$

$$\Rightarrow P(A-B) = P(A) - P(A \cap B)$$

$$\& P(B-A) = P(B) - P(A \cap B)$$

Now find  $P(A \text{ XOR } B)$  okay,  $P(A \text{ XOR } B)$ ,  $A \text{ XOR } B$  means what? Probability of  $A \text{ XOR } B$  is the event that either A or B but not both will happen okay. So if you take A here and this is B okay. Then, this portion is A-B, A occurs B cannot occur and this portion represents B-A that is B can occur but A cannot occur okay, B will occur but A will not occur okay. So when we say that probability of  $A \text{ XOR } B$  okay, it means that we need the probability that either A or B occurs but not both happen together okay not both will happen.

So XOR means exclusive OR function. This means exclusive OR function okay. Now  $A \text{ XOR } B$  means A-B, this is A-B union B-A. So probability of  $A \text{ XOR } B$  will be=probability of A-B+probability of B-A because A-B intersection B-A is= $\phi$ , A-B intersection B-A is= $\phi$ , so probability of  $A \text{ XOR } B$  is= $P(A-B) + P(B-A)$  okay. Now we know that  $P(A) = P(A-B) + P(A \cap B)$  intersection B because this is= $P(A-B) + P(A \cap B)$ .

Because A-B and A intersection B are mutually exclusive, so probability of A will be probability of A-B+probability of A intersection B. Similarly, B-A and A intersection B are mutually exclusive, so  $P(B) = P(B-A) + P(A \cap B)$  okay. So this give you the values of probability of A-B, this is=probability of A-probability of A intersection B and probability of B-A which is probability of B-probability of A intersection B okay.

So let us put the values of  $P(A-B)$  and  $P(B-A)$  what we will get?  $P(A) + P(B) - \text{twice } P(A \cap B)$  okay. So this is how we get the value of  $A \text{ XOR } B$ .

(Refer Slide Time: 41:50)

### Example 8

The probability that a contractor will get a plumbing contract is  $\frac{2}{3}$  and the probability that he will not get an electric contract is  $\frac{5}{9}$ . If the probability of getting only one contract is  $\frac{4}{5}$ , what is the probability that he will get both the contract?

$$\begin{aligned}
 P(A) &= \frac{2}{3}, \text{ where } A \text{ denotes the event that the contractor gets the plumbing contract} \\
 P(B^c) &= \frac{5}{9}, \text{ where } B \text{ denotes the event that the contractor gets the electric contract} \\
 \Rightarrow P(B) &= \frac{4}{9} \\
 P(A \text{ XOR } B) &= \frac{4}{5} \\
 P(A \text{ XOR } B) &= P(A) + P(B) - 2P(A \cap B) \\
 \frac{4}{5} &= \frac{2}{3} + \frac{4}{9} - 2P(A \cap B) \\
 2P(A \cap B) &= \frac{2}{3} + \frac{4}{9} - \frac{4}{5} \\
 &= \frac{30 + 20 - 36}{45} = \frac{14}{45} \\
 P(A \cap B) &= \frac{7}{45}
 \end{aligned}$$

Now let us consider this problem. The probability that a contractor will get a plumbing contract is  $\frac{2}{3}$ . So let us say A denotes the event that the contractor gets the plumbing contract okay. Then, probability of A is  $\frac{2}{3}$  and the probability that he will not get an electric contract. So let us say that B denotes the event that he gets the electric contract okay. So then we are given that  $P(B^c) = \frac{5}{9}$  okay where A denotes the event of that the contractor gets plumbing contract.

Further let B denotes the event where B denotes the event that the contractor gets the electric contract okay. So  $P(B^c) = \frac{5}{9}$  which implies that  $P(B) = \frac{4}{9}$ ,  $P(B^c) = \frac{5}{9}$ , so  $P(B) = \frac{4}{9}$ . Now if the probability of getting only one contract, probability of getting only one contract is  $\frac{4}{5}$ , what is the probability that he will get both the contracts? So here we are given the probability of getting only one contract that is either A or B but not both okay.

So probability of A XOR B is given to us, probability of A XOR B is  $\frac{4}{5}$  okay. Now A XOR B is  $P(A) + P(B) - 2P(A \cap B)$  okay. So  $P(A \text{ XOR } B) = P(A) + P(B) - 2P(A \cap B)$  okay. So this is  $\frac{4}{5} = P(A) + P(B) - 2P(A \cap B)$  okay. So what do we get?  $2P(A \cap B) = P(A) + P(B) - \frac{4}{5}$  okay, so from here we can get the value of A intersection B.

So this is  $\frac{3}{9} \frac{5}{9}$  okay  $\frac{3}{9} \frac{5}{9}$  LCM let us find. So this is 45 okay, so we get  $15 \times 2 = 30$  then  $9 \times 5 = 45$ , so  $5 \times 4 = 20$  and then  $5 \times 9 = 45$ ,  $9 \times 4 = 36$  so we get  $50 - 36$  that is  $50 - 36$  is 14,  $\frac{14}{45}$  okay, so that is the answer in this case okay.

### Example 9

Events A and B are such that  $P(A \cup B) = \frac{1}{2}$ ,  $P(A' \cap B) = \frac{1}{5}$  and  $P(B') = \frac{3}{4}$ . Find (i)  $P(A)$  (ii)  $P(A \cap B')$ .

$$\begin{aligned}
 P(A \cup B) &= P(A) + P(B) - P(A \cap B) \\
 \frac{1}{2} &= P(A) + \frac{1}{4} - \frac{1}{20} \\
 \Rightarrow P(A) &= \frac{1}{2} - \frac{1}{4} + \frac{1}{20} = \frac{10 - 5 + 1}{20} = \frac{6}{20} = \frac{3}{10}
 \end{aligned}$$

$$\begin{aligned}
 P(A' \cap B) &= P(B - A) = \frac{1}{5} \\
 P(B') &= \frac{3}{4} \Rightarrow P(B) = \frac{1}{4} \\
 P(B - A) &= P(B) - P(A \cap B) \\
 \frac{1}{5} &= \frac{1}{4} - P(A \cap B) \\
 P(A \cap B) &= \frac{1}{4} - \frac{1}{5} = \frac{5 - 4}{20} = \frac{1}{20}
 \end{aligned}$$

$$\begin{aligned}
 P(A \cap B') &= P(A) - P(A \cap B) \\
 &= \frac{3}{10} - \frac{1}{20} = \frac{6 - 1}{20} = \frac{5}{20} = \frac{1}{4}
 \end{aligned}$$

Now let us go to this question. Events A and B are such that  $P(A \cup B) = \frac{1}{2}$ ,  $P(A' \cap B) = \frac{1}{5}$ ,  $P(B') = \frac{3}{4}$ . We have to find the probability of A okay. So we are given the probability of  $P(A' \cap B)$  means that this is probability of B-A okay. This is  $\frac{1}{5}$ . Probability of B dash is  $\frac{3}{4}$  implies that probability of B is  $\frac{1}{4}$  okay. Now we need the probability of A okay.

So  $P(B-A)$  okay  $P(B-A) = P(B) - P(A \cap B)$  okay. From B when you subtract A intersection B, you get B-A okay. So B-A is  $\frac{1}{5}$ , so this is  $P(B) - P(A \cap B)$  okay. So we get  $P(A \cap B)$  as  $\frac{1}{4} - \frac{1}{5}$  means that we have  $\frac{1}{20}$  okay. Now  $P(A \cup B) = P(A) + P(B) - P(A \cap B)$ . So  $P(A \cup B)$  is  $\frac{1}{2}$ , so  $\frac{1}{2} = P(A)$  we have to determine,  $P(B)$  we know, this is  $\frac{1}{4}$  and  $P(A \cap B)$  is  $\frac{1}{20}$ .

So we get  $P(A) = \frac{1}{2} - \frac{1}{4} + \frac{1}{20}$  and we have the LCM 20, so we get 10 here okay, here 5, here 1 okay. So  $10 - 5 + 1$ , so  $\frac{6}{20}$ . This is least  $\frac{3}{10}$  okay. So  $\frac{3}{10}$  we get and  $P(A \cap B')$  is  $P(A - B)$  which is  $P(A) - P(A \cap B)$ . So this is  $\frac{3}{10}$ ,  $P(A)$  is  $\frac{3}{10} - P(A \cap B)$  is  $\frac{1}{20}$ . So we get this will be  $\frac{6}{20} - \frac{1}{20}$ , so  $\frac{5}{20}$  and this is  $\frac{1}{4}$  okay. So that is how we get the value of  $P(A \cap B')$ . With this I would like to end my lecture. Thank you very much for your attention.
