Lecture – 45
Discrete Probability Distribution

Hello friends welcome to my lecture on discrete probability distribution let us define random variable if we draw 5 bolts from a lot of bolts and measure the diameter we cannot predict how many bolts will be defective that is will not meet the given requirements hence x = number of defectives. Let us define x to be number of defective then x describes the function which depends on chance.

(Refer Slide Time: 00:56)

Random variable

If we draw 5 bolts from a lot of bolts and measure the diameter, we can not predict how many bolts will be defective, i.e. will not meet the given requirements; hence X = number of defectives, is a function which depends on chance. The life time of a light bulb to be drawn at random from a lot of bulbs also depends on "chance". Thus, roughly speaking, a random variable (also called a stochastic variable or variate) is function whose values are real numbers and depend on chance.

The lifetime of a light bulb to be drawn at random from a lot of bulbs also depends on chance. Thus roughly speaking a random variable also called a stochastic variable or variate is a function whose values are real numbers and depend on chance.

(Refer Slide Time: 01:13)

Random variable cont...

It is a function X which is defined on the sample space S of the random experiment, and its values are real numbers. Further, if a be any real number and I be any interval then set of all outcomes in S for which $X = a$, has a well defined probability and the same is true for the set consisting of all outcomes in S for which the values of X are in I .

nd09lec45

As ideally speaking random variable is a function x which is defined on the sample space S of the random experiment and its values are real numbers. Further if a be any real number and I be any interval then these set of all outcomes in S for which X assumes the value a , has a well defined probability and the same is true for the set consisting of all outcomes in S for which the values of X are in I .

(Refer Slide Time: 01:45)

If in a random experiment, the event corresponding to a number a occurs, then the corresponding random variable X is said to assume the value a and the probability of the event is denoted by $P(X = a)$. Similarly the probability of the event " X assumes any value in the interval $a < X < b$ " is denoted by $P(a < X < b)$.

Now if in a random experiment the event corresponding to a number a occurs then the corresponding random variable X is said to assume the value a and the probability of the event is denoted by $PX=a$ okay similarly the probability of the event X assumes any value in that interval $a < X < b$ is denoted by $Pa < X < b$.

(Refer Slide Time: 02:12)

Random variable cont...

The probability of the event $X \leq c$ (X assumes any value smaller than c or equal to c) is denoted by $P(X \leq c)$, and the probability of the event $X > c$ (X assumes any value greater than c) is denoted by $P(X > c)$.

The probability of an event $X \leq c$ that is X assumes any value any smaller than c or $=c$ is denoted by $PX \leq c$ and the probability of the event $X > c$ that is X assumes any value $>c$ is denoted by $PX > c$.

(Refer Slide Time: 02:30)

Random variable cont...

The event $X \leq c$ and $X > c$ are mutually exclusive, hence

$$P(X \leq c) + P(X > c) = P(-\infty < X < \infty).$$

By axiom (ii), $P(-\infty < X < \infty) = 1$, hence

$$P(X > c) = 1 - P(X \leq c).$$

mod09lec45

The event $X \leq c$ and $X > c$ are mutually exclusive because that intersection is \emptyset hence $PX \leq c + PX > c = P(-\infty < X < \infty)$. We know that if A and B are 2 mutually exclusive events then by then by the axiomatic definition of probability $p(a \cup b) = p(a) + p(b)$. So, here if a denotes the event $X \leq c$ and b denotes $X > c$ then $p(a) + p(b) = p(a \cup b)$ and $a \cup b$ is the real axis that is $-\infty$ to ∞ .

Now by axioms 2 of the definition of probability says that probability of S the samples space $S=1$ so probability of $-\infty < X < \infty = 1$ and therefore probability that $X > c = 1 - \text{probability of } x < c$ from this equation.

(Refer Slide Time: 03:35)

For example, if X is the number that turns up in rolling a fair die, $P(X = 1) = 1/6$, $P(X = 2) = 1/6$, etc. $P(1 < X < 2) = 0$, $P(1 \leq X \leq 2) = 1/3$, $P(0 \leq X \leq 3.2) = 1/2$, $P(X > 4) = 1/3$, $P(X \leq 0.5) = 0$ etc. $P(X=1) + P(X=2) = \frac{1}{6} + \frac{1}{6} = \frac{2}{6} = \frac{1}{3}$
The random variable are either discrete or continuous.

Discrete random variable

A random variable and the corresponding distribution are said to be discrete if the number of values for which X has a probability different from zero, is finite or at most countably infinite. Further, if an interval $a < X \leq b$ does not contain such a value, then $P(a < X \leq b) = 0$.

od09lec45

Now for example suppose X is the number that turns up and rolling a fair dice roll a fair dice then the probability of getting a any number say 1 2 3 4 5 6 is $= 1/6$ okay so probability of $X = 1$ $1/6$ probability of $X = 2$ is also $1/6$. But probability of $1 < X < 2$ okay now takes values 1 2 3 4 5 6 so X is not taking any value in between 1 and 2 and therefore probability that 1 is $< X < 2$ is 0. Probability that $1 \leq X \leq 2$ it includes 2 integers 1 and 2 okay.

So, probability that 1 is $\leq X \leq 2$ is probability that $X=1$ + probability that $X=2$ and that is $= 1/6 + 1/6 = 2/6$ and which is $= 1/3$ okay. So, probability that 1 is $\leq X \leq 2$ is $1/3$ probability that $0 \leq X \leq 2$. Now in this set there are 3 points 1 2 and 3 each 1 has probability $1/6$ so probability of $X=1$ + probability of $X=2$ + probability of $X=3$ is $3/6$ that is $1/2$ and then probability $X > 4$ okay $X > 4$ means X can take values 5 and 6.

So, probability of getting 5 is $1/6$ probability of getting 6 is $1/6$ so probability of $X > 4$ is sum of the 2 probability that is $1/6 + 1/6$ by 6 which is $= 2/6$ and so $1/3$ and probability that $X \leq 0.5$ no value of X satisfies $X \leq 0.5$ because X is taking values 1 2 3 4 5 6. So, probability that $X \leq 0.5$

= 0.5 is 0. Okay the random variables are either discrete or they are continuous okay now let us define a discrete random variable.

A random variable and the corresponding distribution are set to be discrete if the number of values for which X has a probability different from 0 is finite or at most countably infinite. Okay further if an interval $a < X \leq b$ does not contain such a value then probability that $a < X \leq b$ is +0.

(Refer Slide Time: 06:10)

Discrete random variable cont...

Let x_1, x_2, x_3, \dots be the values for which X has a positive probability, and let p_1, p_2, p_3, \dots be the corresponding probabilities. Then $P(X = x_i) = p_i, i = 1, 2, 3, \dots$

We now define the probability function of X which is given by

$$f(x) = \begin{cases} p_j, & \text{when } x = x_j \ (j = 1, 2, 3, \dots) \\ 0, & \text{otherwise.} \end{cases}$$

$f(x) = P(X=x)$
 $f(x_j) = P(X=x_j)$
 $j=1,2,3,\dots$

Since $P(S) = 1$, by axiom (iii), we must have $\sum_{j=1}^{\infty} f(x_j) = 1$.

mod09lec45

Now let x_1, x_2, x_3 be the values for which X has a positive probability and let p_1, p_2, p_3 denote the corresponding probability that is probability of $x=x_i=p_i$ i takes 1 2 3 and so on. Then we define the probability function of X given by f_x takes the value p_j when x takes the value x_j so $f_x = p_j$ for $j=1, 2, 3$ and so on. so that means f_x is nothing but probability that X takes the value x okay.

So, $f_x =$ probability that x takes the value x_j and $j=1, 2, 3$ and so on. Okay so this $p_{x_j} = x_j$ is p_j so $f_x = p_j$ and when x does not take the value x_j then okay f_x takes the value 0. So, now $P(S)=1$ probability of the sample space $S=1$ by axiom 3 of the axiomatic definition of probability. So, we must have sum of the probability = 1 that is $\sum_{j=1}^{\infty} f_x = 1$.

(Refer Slide Time: 07:39)

Discrete random variable cont...

If we know the probability function of a discrete random variable X , then we may compute $P(a < X \leq b)$ as follows:

$$\underline{P(a < X \leq b)} = \sum_{a < x_j \leq b} f(x_j) = \sum_{a < x_j \leq b} p_j. \quad (1)$$

mod09lec15

Now if we know the probability function of a discrete random variable X then we may compute probability that $a < X \leq b$ okay as follows. Probability that $a < X \leq b$ is $\sum_{a < x_j \leq b} f(x_j)$. We will take the sum of the probabilities of the points x_j which lie in the interval a to b okay that is $\sum_{a < x_j \leq b} p_j$.

(Refer Slide Time: 08:03)

Discrete random variable cont...

For closed, open or infinite interval we can compute the probability in a similar manner. Thus the probability function $f(x)$ determines the probability distribution. If X is any random variable, not necessarily discrete then for any real number x there exists the probability $P(X \leq x)$ corresponding to $X \leq x$.

Now for closed open or infinite interval we can compute the probability in a similar manner here you can take $a \leq X \leq b$ that then you can take the closed interval ab okay? you may also take the open from write on the side b that is you can consider $a \leq X < b$ okay you may also take $a = -\infty$ to $b = +\infty$ so you may also consider infinite interval you may also consider open intervals that is $a < X < b$.

Then we will calculate the probability that $a < X < b$ or $a \leq X \leq b$ are probability of manage infinity $< X \leq b$ in a similar manner okay like we have shown here okay. We will take the sum of the probabilities with all those points x_j which lie in a given interval okay. Now if X is any random variable this is true for any random variable not necessarily discrete. If X is any random variable not necessarily discrete.

Then for any real number of X there exist the probability $P(X \leq x)$ corresponding to $X \leq x$ okay so we call it as the cumulative distribution function of X .

(Refer Slide Time: 09:26)

Discrete random variable cont...

Clearly $P(X \leq x)$ is function of x which is called the distribution function of x and is denoted by $F(x)$. Thus, $F(x) = P(X \leq x)$ ✓

Since

$$P(a < X \leq b) = P(X \leq b) - P(X \leq a),$$

we have

$$P(a < X \leq b) = F(b) - F(a).$$

And denote it by F_X okay $P(X \leq x)$ is a function of X which is called the distribution function of x or cumulative distribution function of X and it is denoted by F_X . So, $F_X = P(X \leq x)$. Now probability of $a < x \leq b$ can be written as Probability of $X \leq b$ - Probability of $X \leq a$. So, probability that $A < X \leq b$ can be expressed in terms of the cumulative distribution function this gives you F_b okay using this definition and this gives you F_a okay by the same definition.

So, the distribution function determines the distribution of X uniquely okay and it can be used for computing probabilities. We can compute the probabilities by using the distribution function you can see $F_b - F_a$ gives the probability that $a < X \leq b$.

(Refer Slide Time: 10:24)

Discrete random variable cont...

Thus the distribution function determines the distribution of X uniquely and that it can be used for computing the probabilities. If X is a discrete random variable then (1) implies

$$P(-\infty < X \leq x) = \sum_{x_j \leq x} f(x_j).$$

- $\infty < x_j \leq x$

mod09lec45

Now if X is a discrete random variable then from 1 okay from the definition 1 from the definition probability that $-\infty < x \leq x$ okay $= \sum_{x_j \leq x}$. We will take the sum of the probability is all goes to x_j which lie in the interval $-\infty$ to X that is $x_j \leq x$ okay.

(Refer Slide Time: 10:56)

Example 1

Consider the experiment of rolling a fair die once. Let X denote the number obtained in rolling the die then the possible values of X are 1, 2, 3, 4, 5, 6. Hence, the probability function $f(x) = \frac{1}{6}$ when $x = 1, 2, 3, 4, 5, 6$ and 0 otherwise. The graph showing $f(x)$ and the cumulative distribution function $F(x)$ are as given below;

Now let us consider the experiment of rolling a fair dice once. Let x denote the number obtained in rolling the dice then the possible values of X are 1 2 3 4 5 6 hence the probability function f it takes the value $1/6$ when x takes the value 1 2 3 4 5 6 and $F_x = 0$ otherwise. Now the graphs showing the function F_x and the cumulative distribution function F_x are as given below. You can see here this is our x axis okay and this is the y axis okay.

So, F_x takes the value $1/6$ when X is $= 1$ 2 3 4 5 6 okay at all the values of X 1 2 3 4 5 6 F_x takes the value $1/6$ and it is 0 at all other values of X . Now this is cumulative distribution function of the function cumulative distribution function of the probability function F_x okay so here when X is < 1 okay probability that X is < 1 okay this is $F_x = \text{probability that } X \text{ is } \leq 1$ okay so $F_x =$ let me write like this $F_x = \text{probability that } X \leq 1$.

Now when $X=1$ okay $F_x = P(X \leq 1)$ okay and $P(X \leq 1)$ is $1/6$ so $F_1 = 1/6$ to the left of 1 okay F_x is 0 $F_x = 0$ because the probability $F_x = 0$ okay at $X=1$ $F_1 = 1/6$ and then F_x okay when X takes the value 2 okay $F_x = P(X \leq 2)$ gives you $2/6$ because $X \leq 2$ means we will get the probability of $X = 1$ and $X = 2$ so we get here we write here $F_x = 2/6$ and then when you take $X=3$ okay we reach here okay $F_x = P(X \leq 3)$ so we get $3/6$ that is $1/2$.

And when you take $X=4$ you get $F_x = 4/6$ and we come here then at 5 we come here $5/6$ and at 6 we come here and then after that F_x becomes $= 1$ but guess so if X is > 6 okay $> \text{ or } = 6$ when X is $> \text{ or } = 6$ okay F_x is $= 1$ okay now in between okay if $1 \leq X < 2$ okay if $1 \leq X < 2$ okay if $1 \leq X < 2$ then probability remains 1 okay. Because in this interval 1 to 2 only $X = 1$ lies.

So, here 1 to 2 interval you too take 1 to 2 then the cumulative distribution function remains 1 okay so $F_x = 1$ for the interval $1 \leq X < 2$ similarly $F_x = 2$ when $2 \leq X < 3$ like this. $F_x = 1/6$ okay here it is $2/6$ and then $3/6$ when $3 \leq X < 4$ like this okay. So, this is how we draw the graph of the cumulative distribution function in the case of rolling a fair dice.

(Refer Slide Time: 15:14)

Example 2

Next let us consider the experiment of rolling a pair of dice and let X denote the sum of the numbers appearing on the two dice then the possible values of X are 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12 and the probability function $f(x)$ has the value

x	2	3	4	5	6	7	8	9	10	11	12
$f(x)$	$\frac{1}{36}$	$\frac{2}{36}$	$\frac{3}{36}$	$\frac{4}{36}$	$\frac{5}{36}$	$\frac{6}{36}$	$\frac{5}{36}$	$\frac{4}{36}$	$\frac{3}{36}$	$\frac{2}{36}$	$\frac{1}{36}$

because there are $6 \times 6 = 36$ possible equally likely outcomes, each of which has the probability $\frac{1}{36}$; we have $X = 2$ for just one outcome, e.g. (1,1) (where the first number refers to the first die and the second number to the other die); we have $X = 3$ in the case of two outcomes (1,2) and (2,1) hence $P(X = 2) = \frac{2}{36}$ and so on.

Now let us take the experiment of rolling a pair of dice okay? we have 2 dice we roll them together okay then X denote the sum of the numbers appearing on the 2 dice then the possible values of X are 2 3 4 5 6 7 8 9 10 11 12 okay the probability function F_x has the value. Now when we will get the number 2 sum of the numbers on the 2 dice will be =2 when each one has each one shows 1 on.

Okay so that means 1 1 okay on the dice 1 dice 1 the first number shows dice 1 second number shows dice 2 okay so first number on the dice 1 we get 1 on the dice 2 we get 1. Then the sum will be 2 and each one has probability $1/6$. So, having 1 1 that is sum 2 will turn up will be the sum of $X=2$ when we will have 1 1 on both the dice okay and probability for that is $1/6 \times 1/6$ that is $1/36$.

Now when the sum will be 3 the sum will be 3 if we have on dice 1 we have 1 on dice 2 we have 2 on dice 1 we have 2 on dice 2 we have 1 okay now there are 2 possibilities when the sum will be 3 okay? now this has probability $1/6$ this has probability $1/6$ so having 1 2 is having probability $1/36$ and 2 1 will also have a probability $1/36$. So, total probability is $2/36$ and we get $2/36$. Now sum will be 4 sum of the two dice will be 4 if we have 1 3 3.

Okay 2 2 there are 3 possibilities 1 3 3 1 2 2 okay each 1 has probability $1/36$ so we have $3/36$ similarly 5 5 can come when we have 1 4 4 1 2 3 3 2 and then so we have 4 possibilities each one

has probability $1/36$. So, we get the probability of having some 5 as $4/36$ so in a similar manner we can compute the probabilities for having $X=6, 7, 8, 9, 10, 11$ now 12 will come 1 each 1 each dice shows 6.

Okay so that means 6 6 so this is $1/6$ probability of this is having 6 on 1 dice is $1/6$ so $1/6 * 1/6$ so this has probability $1/36$ so we have $1/36$ now you can sum these probabilities okay $1 + 2 + 3 + 4 + 5 + 6 + 5 + 4$ this comes out to be $36/36$ and so sum of probabilities is $= 1$ now there are 36 possible outcomes equally likely outcomes each of which has the probability $1/36$ $X=2$ comes for 1 1 we have discussed okay we are in the first dice number refers to the first dice.

Second number to the other dice we have $X=3$ in the case of 2 outcomes 1 2 and 2 1 okay so probability that $X=2$ is $2/36$ and so on.

(Refer Slide Time: 18:33)

The graph showing $f(x)$ and the cumulative distribution function $F(X)$ are as given below:

Figure : Fig.2

Now let us look at the graph okay so you can see here this is your $1/6$ okay now there is 1 2 3 4 5 6 7 8 9 10 11 12 okay so we can have sum 2 okay sum can come sum cannot be 1 okay sum can be 2 so this is 2 3 4 5 6 7 8 9 10 11 and 12 okay now 2 2 2 has probability $1/36$ okay so this is $1/36$ there is 36 probability that X has a value 3 is a $2/36$ so this is double of this okay so $2/36$ then this is $3/36$ at 4 $3/36$ at 5 $4/36$ this is $4/36$ okay at 6 $5/36$.

So, this is $5/36$ and 7 is $6/36$ $6/36$ means $1/6$ okay so you can see this is $1/6$ okay at 7 the probability is $6/36$ that is a $1/6$ okay so and then at 8 the probability is $5/36$ same as the probability at 6 okay so you have these same hike here at 8 okay then 9 has the probability $4/36$ $4/36$ means the probability for having the sum 5 okay and then 10 10 has a probability $3/36$ so it is of the same height as height at 4 .

And then 10 11 11 has $2/36$ so it has the same height as the height at 3 okay and then the probability that $X = \text{sum} = 12$ has the same height as height at $X = 2$ okay. So, this is the graph of the probability distribution of X where X denote the sum of the numbers on the 2 dice when we roll them okay.

(Refer Slide Time: 20:43)

Now this is cumulative distribution function we can see here that this is 2 3 4 5 this is 2 3 4 5 6 7 8 9 10 11 12 okay so probability that F_x Probability that $X \leq x$ okay so if you take X to be 2 okay so let X be 2 okay then this is probability that actually \leq or $= 2$ is a probability of having $X = 2$ $X = 2$ means 1 1 that means $1/36$. Okay so you can see this is $1/36$ then at $x = 3$ we have to $2/36$ okay.

So $X=3$ has probability $2/36$ $X=1$ has probability $1/36$ so $1/36 + 2/36$ we have to add the probability at $X=1$ see this is = probability that $X=1$ + probability that $X=2$. So, this is $= 1/36 + 2/36$ so we get $3/36$ okay so this is $3/36$ this one is $3/36$ okay and then you find the F_x for

X=4 okay. So, F_x this will be F_x okay so F_x where $X < 4$ $PX \leq 4$ okay let X be 4. So, then this is probability that $X=1$ $X=2$ $X=3$ $X=2$ not $X=1$ 23 and 4.

And here we have to write 2 and 3 okay 2 and 3 so this will be $1/36$ $2/36$ and 4 comes when we take 1 3 3 1 and 22 okay we get $3/36$ so this comes $=6/36$. Okay $6/36$ and when you take $X=5$ here okay $X=5$ we will see it comes to be $10/36$ so we have $F_x = PX \leq 5$ and we get $P_x=2$ $PX=3$ $X=4$ $X=5$ okay which is $=1/36$ $2/36$ $3/36$ so probability that $X=2+$ probability that $X=3+$ probability of $X=4$ is $6/36$ we have to add the probability of $X=5$.

When $X=5$ comes when we have 1 4 4 1 2 3 2 okay that means we have 4 cases. So, $4/36$ okay so $6/36 + 4/36$ so we get $10/36$ so you can see here when $X=5$ it is $10/36$ okay and similarly we can calculate and when X is 12 okay when X is 12 the sum of the probability becomes $=1$ so when $X=12$ okay $F_x = PX \leq X$ will be $=1$ and when X is >12 so thus when X is ≥ 12 $F_x=1$ so this is like this. So, this is the cumulative distribution function of F_x .

(Refer Slide Time: 25:35)

Mean and variance

The mean of a discrete random variable is denoted by μ and defined by

$$\mu = E(X) = \sum_i x_i f(x_i)$$

and the variance is given by

$$Var(X) = \sigma^2 = \sum_i (x_i - \mu)^2 f(x_i) = E(X^2) - (E(X))^2$$

mod09lec45

Handwritten derivations:

$$\begin{aligned} \mu &= E(X) = \sum_i x_i f(x_i) \\ &= \sum_i (x_i^2 - 2\mu x_i + \mu^2) f(x_i) \\ &= \sum_i x_i^2 f(x_i) - 2\mu \sum_i x_i f(x_i) + \mu^2 \sum_i f(x_i) \\ &= E(X^2) - 2\mu E(X) + \mu^2 \\ &= E(X^2) - \mu^2 = E(X^2) - (E(X))^2 \end{aligned}$$

Now the mean of a discrete random variable when you have a discrete random variable the mean of the discrete random variable is given by $\sum_j x_j f(x_j)$ where x_j are the values taken by the random variable X okay. We multiply x_j by the corresponding probabilities and take the sum/ j the variance is given by variance of $X = \sigma^2$ which is $\sum_j (x_j - \mu)^2 f(x_j)$ that is we multiply the deviation of x_j from the mean square it.

And then multiply by the probabilities of a corresponding probabilities and take the sum/ j. Now this expression comes out to be expectation of X square - expectation of X whole square we can easily see this. Let us write $\sum x_j - \mu$ whole square * $F_{xj} = \sum x_j^2 - 2\mu \sum x_j + \mu^2 \sum F_{xj}$ then this will be $\sum x_j^2 * F_{xj} - 2\mu$ is a constant $\sum x_j * F_{xj} + \mu^2 \sum F_{xj}$ okay.

Now this is $\sum x_j^2 F_{xj}$ is expectation of X square okay the first term first sum is $E x^2 - 2\mu \sum x_j F_{xj}$ over here is μ . So, -2μ square and then $+\mu^2 \sum F_{xj} = 1$ sum of the probability = 1 this is $E x^2 - \mu^2$ okay which is $E x^2 - (E x)^2$ okay we have this result okay. So, variation of x can be expressed in terms of the expectation it is expectation of x square - expectation of x whole square.

(Refer Slide Time: 28:10)

Example 3

Let X denote the discrete random variable which denotes the minimum of the two numbers that appears in a single throw of a pair of fair dice. Determine the discrete probability distribution of X .

Ans:

$x = x_i$	1	2	3	4	5	6
$P(x = x_i) = f(x_i)$	$\frac{11}{36}$	$\frac{9}{36}$	$\frac{7}{36}$	$\frac{5}{36}$	$\frac{3}{36}$	$\frac{1}{36}$

mod09lec45

Handwritten notes on the right side of the slide:

- $(1,1), (1,2), (1,3), (1,4), (1,5), (1,6)$
- $(2,1), (2,2), (2,3), (2,4), (2,5), (2,6)$
- $(3,1), (3,2), (3,3), (3,4), (3,5), (3,6)$
- $(4,1), (4,2), (4,3), (4,4), (4,5), (4,6)$
- $(5,1), (5,2), (5,3), (5,4), (5,5), (5,6)$
- $(6,1), (6,2), (6,3), (6,4), (6,5), (6,6)$

Now let us consider this problem let X denote the discrete the minimum of the two numbers that appears in a single throw of a pair of fair dice okay? Then determine the discrete probability distribution of X okay so now if the minimum of the numbers on both the dice is 1 okay this can happen how many in how many cases are there were minimum will be 1 1 1 okay 1 2 1 3 1 4 1 5 1 6 okay.

And then we have 6 1 5 1 4 1 3 1 2 1 okay 11 we have already taken so there are 11 cases 1 2 3 4 5 6 7 8 9 10 11 each one has a probability $1/36$ so we have $11/36$ probability okay similarly if you want the minimum on the of the 2 numbers to be 2 then the cases are 1 2 2 1 2 3 3 2 2 4 4 2 2 5 5 2 2 6 6 2 and 2 2 okay so we have one pair here one pair here one pair here no this will not come because the minimum be 1 to be 2 okay.

So, this will not come minimum we want to be 2 there minimum will be 1 okay. So, here so we have two cases here two cases here two here okay 8+19. So, we have $9/36$ so similarly if we want the minimum to be 3 there will be 7 cases okay each one will have probability $1/36$. So, we will have $7/36$ okay so this is the probability distribution of the discrete random variable which is the minimum of the 2 numbers that appears in a single throw of a pair of fair dice.

(Refer Slide Time: 30:27)

Example 4

A stack of Rs.44 is to be won between two players A and B, whoever get 6 in a throw of die alternately. Determine their respective expectations if A starts the game.

Ans: $E(A)=Rs.24$ and $E(B)=Rs.20$.

$$\begin{aligned}
 P(A \text{ wins}) &= \frac{1}{6} + \frac{5}{6} \times \frac{5}{6} \times \frac{1}{6} + \frac{5}{6} \times \frac{5}{6} \times \frac{5}{6} \times \frac{1}{6} + \dots \\
 &= \frac{\frac{1}{6}}{1 - \left(\frac{5}{6}\right)^2} = \frac{\frac{1}{6}}{1 - \frac{25}{36}} = \frac{1}{6} \times \frac{36}{11} = \frac{6}{11} \\
 E(A) &= \frac{6}{11} \times 44 = Rs.24 \\
 P(B \text{ wins}) &= \frac{5}{6} \times \frac{1}{6} + \frac{5}{6} \times \frac{5}{6} \times \frac{5}{6} \times \frac{1}{6} + \frac{5}{6} \times \frac{5}{6} \times \frac{5}{6} \times \frac{5}{6} \times \frac{1}{6} + \dots \\
 E(B) &= \frac{5}{11} \times 44 = Rs.20 = \frac{\frac{5}{6}}{1 - \left(\frac{5}{6}\right)^2} = \frac{5}{6} \times \frac{36}{11} = \frac{30}{11}
 \end{aligned}$$

Now let us take the example for a stack of rupees 44 is to be won between two players and be whoever gets 6 in it throw of dice alternatively. Now determine their respective expectations if A starts the game okay? So let us find the probability that A wins so probability that A wins okay if he if he gets 6 in the first throw he will win. Okay so probability of A wins will be $1/6$ okay suppose he does not get 6 in the first throw then what will happen? B will get a chance okay?.

So, then B should not win because we want A to okay so B should not win so in the next case what will happen? $5/6$ okay because if the if in the first throw he does not get $1/6$ that means the

probability will be $\frac{5}{6}$ and then we will get a chance we should also not get $\frac{1}{6}$ so the probability $\frac{5}{6}$ and then A gets the chance A should if we want A to win now then the probability will be $\frac{1}{6}$. Because he should throw 6.

Now if he does not throw 6 then again the probability will be $\frac{5}{6}$ it will go to the player B again so $\frac{5}{6} * \frac{5}{6} * \frac{5}{6}$ okay and then $\frac{5}{6} * \frac{1}{6}$ and he does not get in the first chance he does not get 6 the probability will be $\frac{5}{6}$. Then B also does not get $\frac{1}{6}$ the probability is $\frac{5}{6}$ then A gets the chance the probability will be $\frac{1}{6}$ if he wins okay if he does not win then $\frac{5}{6} * \frac{5}{6} * \frac{5}{6}$ then we will get a chance we should not throw 6 okay.

So $\frac{5}{6}$ then A will win if it throw 6 that will be probability $\frac{1}{6}$ so and so on okay. So, this is a geometric progression and the sum of this series $A/1-R$ is $\frac{1/6 - 5/36}{1 - 5/6}$ so this is $\frac{1/6 - 5/36}{1/6}$ and this comes out to be $\frac{1/6 * 36}{11}$ so we get $\frac{6}{11}$ okay. So, determine the their respective expectations so expectation of A will be = probability that A wins so that is $\frac{6}{11} * \text{the amount that is 44}$ so rupees 24 okay.

So, determine the respective expectation of A okay will be 24 similarly probability that B wins because A starts the game okay? So B will win because if A does not get $\frac{1}{6}$ so that means $\frac{5}{6} * \frac{1}{6}$ B will win if he throws 6 so $\frac{5}{6} * \frac{1}{6}$. Now if B does not throw $\frac{1}{6}$ then $\frac{5}{6} * \frac{5}{6}$ then A should not throw 6 $\frac{5}{6}$ then B will throw $\frac{1}{6}$ B will throw 6 so $\frac{1}{6}$ okay? And then we can similarly have so $\frac{5}{6} * \frac{5}{6} * \frac{5}{6}$ now B does not throw 6 so $\frac{5}{6}$ A does not throw $\frac{1}{6}$ so $\frac{5}{6} * \frac{1}{6}$ and so on.

Okay now the sum of the series is $\frac{5/36 - 1/11}{1 - 5/6}$ whole square so this time it is $\frac{5/36 - 1/11}{1/6}$ okay so we get $\frac{5}{11}$. So EB the expectation of B will be $= \frac{5}{11} * 44$ so that means rupees 20. So, expectation of A is 24 rupees expectation of B is 20 rupees.

Discrete uniform distribution

If X takes finite number of values x_1, x_2, \dots, x_n and all of these are equally probable i.e. $f(x_1) = f(x_2) = \dots = f(x_n) = \frac{1}{n}$ then X is said to follow a discrete uniform distribution. For example X = number shown by fair die

x	1	2	3	4	5	6
$f(x)$	$\frac{1}{6}$	$\frac{1}{6}$	$\frac{1}{6}$	$\frac{1}{6}$	$\frac{1}{6}$	$\frac{1}{6}$

The discrete uniform distribution is generally used if the random variable takes a finite number of values and all these values are supposed to occur equally likely.

od09lec45

Now let us discuss discrete uniform distribution if X takes finite number of values x_1, x_2, \dots, x_n because we have said when we defined the discrete random variable we have said that X either takes discrete number of values or countably infinite number of values discrete in the case of discrete uniform distribution X will take only a finite number of values okay? So let us say the values are x_1, x_2, \dots, x_n and all of these are equally probable.

Because each one has equal probability so that means probability of having $x=x_1, x=x_2, \dots, x=x_n$ each one will be $\frac{1}{n}$ because they are all equal okay? And total probability is 1 now X is said to follow a discrete uniform distribution okay? If x takes the finite number of values okay and all of these values are equally probable okay? Now let us say for example x is = number shown by a fair dice okay when we have a fair dice the number shown by the dice when it is thrown okay.

The numbers are 1, 2, 3, 4, 5, 6 and they are all equally probable okay? So each one has the probability $\frac{1}{6}$. So, the discrete uniform distribution is generally used if the random variable takes a finite number of values and all these values are supposed to occur equally likely. So, number shown by a fair dice is an example of a uniform discrete distribution. Now let us suppose let us consider this problem.

Example 5

If a ticket is drawn from a box containing 10 tickets numbered 1 to 10 inclusive. Find the probability that the number drawn

(a) less than 4,

(b) even number,

(c) prime number,

(d) find the mean and variance of the random variable X .

Ans: (a) $\frac{3}{10}$ (b) $\frac{1}{2}$ (c) $\frac{2}{5}$ (d) 8.25.

$$X = \{1, 2, 3, \dots, 10\}$$

$$P(X < 4) = P(X=1) + P(X=2) + P(X=3)$$

$$= \frac{1}{10} + \frac{1}{10} + \frac{1}{10} = \frac{3}{10}$$

$$P(X = \text{even number}) = \frac{5}{10} = \frac{1}{2}$$

$$P(X = \text{prime no.}) = \frac{4}{10} = \frac{2}{5}$$

$$\text{Mean} = E(X) = \sum_{x=1}^{10} x P(X=x)$$

$$= \sum_{x=1}^{10} x \cdot \frac{1}{10} = \frac{1}{10} \sum_{x=1}^{10} x = \frac{1}{10} \cdot \frac{10(11)}{2} = 5.5$$

If a ticket is drawn from a box containing 10 tickets number 1 to 10 inclusive okay? Find the probability that the number is <4 okay? So when we draw a ticket from the box okay? all the tickets x takes values 1 2 3 4 5 and so on up to 10. Okay x takes the value 1 2 3 4 5 6 so on and so on up to 10 okay find the and each number okay has the same probability they are all equally probable of being drawn.

It is the case of a discrete uniform distribution we want the probability that the number drawn is <4 okay? so $p x < 4$ we want $p x < 4$ means 1 2 3 okay. So, each 1 has probability $1/10$ so $PX=1+PX=2+PX=3$ so it could be any number $PX=1$ or $X=2$ or $X=3$ each number has an equal probability $1/10$ so $1/10+1/10+1/10$ when you take it from the 10 tickets which are numbered from 1 to 10 okay?.

The probability of trying a ticket will be having any number say X where X takes value 1 to 10 will be $1/10$ even number okay so probability then X is an even number now even numbers are 2 4 6 8 and 10 so there are 5 possibilities okay so $5/10$ $1/2$ prime number prime numbers are 2 3 5 7 okay each 1 has probability $1/10$ okay so probability that X is prime. It is $=4/10$ or $2/5$ so okay find the mean and variants of the random variable X okay.

Now mean will be = expectation of X so $\sigma PX=x$ takes values from 1 to 10 again now what we have $\sigma x=1$ to 10 $XPX=x$ takes value 1 to 10 each number has probability $1/10$ so

$X \sim 1/10$ so $\sum_{X=1}^{10} X$ which is $1/10 \cdot 10 \cdot 10 + 11 \cdot 11/2$ because $\sum n = n \cdot (n+1)/2$. So, this is this term will cancel and you get 5.5 okay so expectation is 5.5 okay? Then variance = expectation of X^2 - expectation of x whole square okay?

So expectation of X^2 let us find okay? Just find expectation of X^2 .

(Refer Slide Time: 40:27)

$$\begin{aligned}
 E(X^2) &= \sum_{x=1}^{10} x^2 P(X=x) & \sum n^2 &= \frac{1}{6} n(n+1)(2n+1) \\
 &= \sum_{x=1}^{10} x^2 \cdot \frac{1}{10} = \frac{1}{10} \sum_{x=1}^{10} x^2 = \frac{1}{10} \times \frac{1}{6} \times 10 \times 11 \times 21 = \frac{77}{2} \\
 \text{Now} \\
 \text{Var}(X) &= E(X^2) - (E(X))^2 \\
 &= \frac{77}{2} - \left(\frac{11}{2}\right)^2 \\
 &= \frac{154 - 121}{4} = \frac{33}{4} = 8.25
 \end{aligned}$$

This is $\sum X^2 \cdot P(X=x)$ so x varies from 1 to 10 so this is $\sum_{x=1}^{10} x^2$ and $\cdot 1/10$ okay so $1/10 \sum X^2$ x varies from 1 to 10 we know $\sum n^2$ okay it is $1/6 n \cdot (n+1) \cdot (2n+1)$. So, let us apply this formula so $1/10$ n is 10 here okay so $10 \cdot 10 + 11 \cdot 20 + 121$ okay so this cancels with this and what we have here 3 okay $77/2$. Okay now variance of X = expectation of X^2 - expectation of x whole square.

So, this is $77/2$ and $E(X)$ came out to be $11/2$ okay so $(11/2)^2$ whole square. So, this is $154 - 121$ so we get here $33/4$ so that means 8.25 okay. So, variance comes out to be 8.25 okay now so with this I would like to end my lecture thank you very much for your attention.
