Lecture – 48
Continuous Probability Distribution

Hello friends. Welcome to my lecture on Continuous Probability Distribution. Let s be a sample space which is an interval of the real line or have points defined in a continuum. For such sample spaces, we define the random variable in such a way that they take all values in an interval of values.

(Refer Slide Time: 00:46)

The slide features a blue header bar at the top. Below it, a blue box contains the title "Continuous random variables". The main text of the slide is in black, defining a sample space S as an interval of the real line or a set of points in a continuum, and explaining how random variables are defined to take values in an interval. Examples provided are the life of an electron tube, service time required to complete a job, and heights of individuals. The slide footer includes the IIT Roorkee logo, the text "IIT ROORKEE", "NPTEL ONLINE CERTIFICATION COURSE", and the number "2".

Continuous random variables

Let S be a sample space which is an interval of the real line or have points defined in a continuum. For such sample spaces, we define the random variable in such a way that they take all values in an interval of values. For example we can define random variables to denote the life of an electron tube, service time required to complete a job, heights of individuals.

IIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 2

For example, we can define the random variable to denote the life of an electron tube, service time required to complete a job, heights of individuals, okay. They all come under continuous random variables. So such random variables are all continuous random variables.

(Refer Slide Time: 01:04)

Definition

A continuous random variable is a random variable defined on a sample space S and which takes all values in an interval with probability P defined for events of S . Continuous random variable X can be specified by its cumulative distribution function

$$F_X(x) = P(X \leq x), -\infty < x < \infty.$$

$$= \int_{-\infty}^x f_X(t) dt$$

Now a continuous random variables is a random variables defined on a sample space S , okay and which takes all values in an interval with probability P defined for a events of S . Continuous random variables X can be specified by its cumulative distribution function. cumulative distribution function is the probability that, we denote it by $F_X(x)$, X is the continuous random variable, okay. F denotes the cumulative distribution function.

So $F_X(x)$ is probability that X takes the value less than or equal to x where x belongs to the interval $-\infty$ to ∞ .

(Refer Slide Time: 01:00)

Properties

- 1. $F_X(x)$ is a monotonic non-decreasing function of x because $F_X(x_2) - F_X(x_1) = P(x_1 \leq X \leq x_2) \geq 0$, since probability is non-negative.
- 2. $\lim_{x \rightarrow -\infty} F_X(x) = \lim_{x \rightarrow -\infty} P(X \leq x) = 0$ $F_X(x_2) = P(X \leq x_2)$
- 3. $\lim_{x \rightarrow \infty} F_X(x) = \lim_{x \rightarrow \infty} P(X \leq x) = 1$ $F_X(x_1) = P(X \leq x_1)$
- 4. $F_X(x)$ is right continuous. $\lim_{h \rightarrow 0^+} F_X(x+h) = F_X(x)$ $F_X(x_2) - F_X(x_1) = P(X \leq x_2) - P(X \leq x_1)$
 $= P(x_1 < X \leq x_2)$
 $\geq 0, x_1 < x_2$

Properties

For a continuous random variable we define a function corresponding to the probability distribution of a discrete random variable. It is denoted by $f_X(x)$ and is defined as the derivative of the distribution function $F_X(x)$ at x .

Now this $F_X(x)$, is monotonically non-decreasing function of x , okay. Because you can find

$F(x_2) - F(x_1)$, this will come out to be probability that x_1 is less than or equal to X less than or equal to x_2 . $F(x_2)$ = Probability that X is less than or equal to x_2 and $F(x_1)$ = probability that x is less than or equal to x_1 , okay. So $F(x_2) - F(x_1)$, okay is the probability that X is less than or equal to x_2 - probability that X is less than or equal to x_1 , okay.

So this is probability that X is less than or equal to x_2 , okay. Since probability is a non-negative function, this is greater than or equal to 0, okay. So whenever x_1 is less than, so here we are assuming that $x_1 < x_2$. So when $x_1 < x_2$, $F(x_2) - F(x_1)$ is greater than or equal to 0 that is $F(x_1)$ is less than or equal to $F(x_2)$. So $F(x)$ is a monotonically non-decreasing function of X . Now limit x tends to $-\infty$.

Limit x tends to $-\infty$ $F(x)$ is limit x tends to $-\infty$ probability that x is less than or equal to x , that is equal to 0, okay. Because probability that X is less than or equal to x when x tends to $-\infty$, okay, will be equal to 0 and when limit, because this is nothing but, this is probability X less than or equal to x . This is nothing but $-\int_{-\infty}^x f(x) dx$, we shall see later on.

We shall see later on that this is, $F(x)$ is nothing but integral over $-\infty$ to x $f(x) dx$. So when x tends to $-\infty$, $f(x)$ tends to 0. So limit x tends to $-\infty$ P_x less than or equal to x is 0 and here limit x tends to $f(x)$ that is limit x tends to infinity, probability that x is less than or equal to x will be equal to 1, okay. Because it will be then the total probability. Total probability will be equal to 1.

$F(x)$ is right continuous, okay. The right continuous means limit h tends to 0^+ , okay. $F(x+h) = F(x)$, okay. So it is right continuous. Now for a continuous random variable, we define a function corresponding to the probability distribution of a discrete random variables. For a continuous random variables, we define a function corresponding to the probability distribution of a discrete random variable.

It is denoted by $f(x)$. So this is known as the probability density function for the random variables, continuous random variable x and it is defined as the derivative of the distribution

function $f_X(x)$. So this probability density function $f_X(x)$ is defined as the derivative of the distribution function $F_X(x)$ at x , okay.

(Refer Slide Time: 05:18)

Definition and Properties

The probability density function $f_X(x)$ of a continuous random variable X is defined by

$$f_X(x) = \frac{d}{dx} F_X(x), \quad -\infty < x < \infty$$

$$\Rightarrow F_X(x) = \int_{-\infty}^x f_X(t) dt$$

(i) $f_X(x) \geq 0, \quad -\infty < x < \infty$ because $F_X(x)$ is monotonically increasing

(ii) $\int_{-\infty}^{\infty} f_X(x) dx = 1$ because $\lim_{x \rightarrow \infty} F_X(x) = 1 = \int_{-\infty}^{\infty} f_X(t) dt$

Note that $f_X(x)$ itself is not a probability. It can be greater than 1 for some values of x .

ET ROOIRGE NPTEL ONLINE CERTIFICATION COURSE 5

So the probability density function $f_X(x)$ of a continuous random variable is defined as d/dx of $F_X(x)$, okay where x varies over $-\infty$ to ∞ . From this equation, one can see that $f_X(x)$ is integral over $-\infty$ to x of $f_X(t) dt$, okay. So you can see since $F_X(x)$ is a monotonically increasing function, okay, its derivative must be non-negative, okay. This follows because $F_X(x)$ is monotonically increasing. So its derivative is non-negative.

So $f_X(x)$ is greater than or equal to 0 and further more limit x tends to infinity $F_X(x)=1$, okay. We have assumed that limit x tends to infinity $F_X(x)=1$, okay. So from there, okay, this will be equal to integral over $-\infty$ to ∞ of $f_X(t) dt$, okay. So when x tends to infinity, $F_X(x)$ tends to integral over $-\infty$ to ∞ of $f_X(t) dt$ and limit x tends to infinity $F_X(x)=1$, so integral over $-\infty$ to ∞ of $f_X(x) dx=1$. Now we can note that $f_X(x)$ itself is not a probability. It can be greater than 1 for some values of x , okay. The integral of $f_X(x)$ over $-\infty$ to ∞ is 1, okay.

(Refer Slide Time: 07:10)

Example 1

Consider the distribution function

$$F_X(x) = \begin{cases} 0 & x < 0 \\ 2x & 0 \leq x \leq \frac{1}{2} \\ 1 & x > \frac{1}{2} \end{cases}$$

The corresponding probability density function is

$$f_X(x) = \begin{cases} 0 & x < 0 \\ 2 & 0 < x < \frac{1}{2} \\ 0 & x > \frac{1}{2} \end{cases}$$

So consider the distribution function. So this is our distribution function, cumulative distribution function $f_X(x)=0$ when $x<0$, $2x$ for $0 \leq x \leq \frac{1}{2}$ and 1 when $x>\frac{1}{2}$, okay. So let us find its derivative d/dx of $f_X(x)$. By our definition, this is $f_X(x)$, probability that the function. So $f_X(x)$ will be equal to 0 when $x<0$, okay, derivative of 0 is 0 . And then $0 \leq x \leq \frac{1}{2}$, okay.

So here the derivative will be 2 , derivative of $2x$ will be 2 . And it will be over the interval $0 < x < \frac{1}{2}$. Why? Because if you draw the graph of this cumulative distribution function, so it is 0 for $x<0$, okay. And then 0 to $\frac{1}{2}$, it is $2x$. It is given by $2x$. So that means it is a straight line. This is $\frac{1}{2}$ here. So it is like this, okay. At $x=\frac{1}{2}$, it is 1 . So this is 1 , okay. So we have this, okay. And then $x>\frac{1}{2}$, it is 1 , okay.

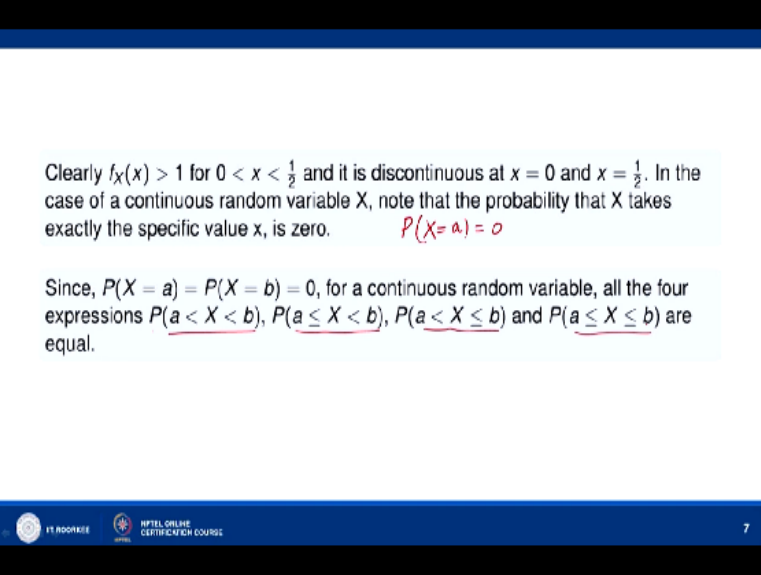

So like this, okay. Now you can see at $x=0$ and at $x=\frac{1}{2}$, it is not differentiable. Because the left hand derivative is 0 , right hand derivative is 2 , okay. So it is not differentiable at 0 . It is not differentiable at $\frac{1}{2}$, okay. So $f_X(x)$ is not differentiable, although it is continuous throughout over $-\infty$ to ∞ but is not differentiable at $x=0$ and $x=\frac{1}{2}$. Elsewhere it is differentiable. So in the interval, open interval $0 < x < \frac{1}{2}$, the derivative of $f_X(x)=2$. And when $x>\frac{1}{2}$, its derivative is 0 .

So you can see the probability density function is taking value 0 over the interval $-\infty$ to 0 . So that means here up to this, it is 0 everywhere and then it is 2 over 0 to $\frac{1}{2}$ interval, okay. So it is over

0 1/2, it is 2, okay and this is f_{xx} . This is f_{xx} , cumulative distribution function, okay. And now here then it takes value 0. So from here onwards, it takes value 0, okay. So this f_{xx} can take value other than 1.

It can take value greater than 1. Here it is taking value 2, okay. But the integral of f_{xx} over $-\infty$ to ∞ must be equal to 1, that you can see. So $\int f_{xx} dx$, this will be equal to integral, because over $-\infty$ to 0, it is 0. Over 1/2 to ∞ , it is 0. It is non-0 over the interval 0 1/2. So this is 0 to 1/2 and $2dx$. This is equal to $2 \cdot \frac{1}{2}$ which is equal to 1, okay. And moreover, it is non-negative, f_{xx} is greater than or equal to 0 for all x . So it is probability density function.

(Refer Slide Time: 11:00)

Clearly $f_X(x) > 1$ for $0 < x < \frac{1}{2}$ and it is discontinuous at $x = 0$ and $x = \frac{1}{2}$. In the case of a continuous random variable X , note that the probability that X takes exactly the specific value x , is zero. $P(X = a) = 0$

Since, $P(X = a) = P(X = b) = 0$, for a continuous random variable, all the four expressions $P(a < X < b)$, $P(a \leq X < b)$, $P(a < X \leq b)$ and $P(a \leq X \leq b)$ are equal.

7

Now let us go to, so here I have explained clearly $f_{xx} > 1$ for $0 < x < 1/2$. It is discontinuous at $x=0$. You can see, it is discontinuous at $x=0$ and also discontinuous at $x=1/2$. In the case of a continuous random variable x , note that the probability that X takes exactly the specific value x is equal to 0. That means probability that X takes the value a , okay, are $x=0$, okay.

So since $PX=a=PX=b=0$ for a continuous random variables, all the 4 expression probability of $a < X < b$, probability a less than or equal to $x < b$, $z < X$ less than or equal to b , probability of a less than or equal to X less than or equal to b are all equal, okay.

(Refer Slide Time: 11:50)

Since $P(a < X \leq b) = \int_a^b f_X(t)dt$, it is the area under the curve $f_X(x)$ between $x = a$ and $x = b$.

$$\begin{aligned} P(a < X \leq b) &= P(X \leq b) - P(X \leq a) \\ &= F_X(b) - F_X(a) \\ &= \int_{-\infty}^b f_X(x)dx - \int_{-\infty}^a f_X(x)dx \\ &= \int_a^b f_X(x)dx \end{aligned}$$

Now probability of $a < X$ less than or equal to b is integral over a to b $f_X(x)dx$ because probability $a < X$ less than or equal to b , this is equal to probability that X is less than or equal to b - probability that X less than or equal to a , okay. So this is $F_X(b) - F_X(a)$ we can say, okay. And this is equal to integral over $-\infty$ to b $f_X(x)dx$ - integral over $-\infty$ to a $f_X(x)dx$, okay. Since $a < b$, okay, is equal to integral over a to b $f_X(x)dx$, okay.

So $f_X(x)dx$ we can write, okay. So it is the area under the graph of $f_X(x)$ function, okay from over the interval a to b . So it is the area under the graph of $f_X(x)$ between $x=a$ and $x=b$, okay as shown in this figure.

(Refer Slide Time: 13:12)

Example 2

Consider the following function. Show that $f_X(x)$ is the probability distribution function and find its cumulative distribution function.

$$f_X(x) = \begin{cases} 4x & 0 \leq x \leq \frac{1}{2} \\ 4(1-x) & \frac{1}{2} \leq x \leq 1 \\ 0 & \text{otherwise} \end{cases}$$

Area of triangle
 $\frac{1}{2} \times \text{base} \times \text{height}$
 $= \frac{1}{2} \times 1 \times 2$
 $= 1 = \int_{-\infty}^{\infty} f_X(x)dx$
 $= \int_{-\infty}^{\infty} f_X(x)dx$

$$\begin{aligned} \int_{-\infty}^{\infty} f_X(x)dx &= 1 \\ &= \int_0^{\frac{1}{2}} 4x dx + \int_{\frac{1}{2}}^1 4(1-x) dx \\ &= 4 \left(\frac{x^2}{2} \right)_0^{\frac{1}{2}} + 4 \left(x - \frac{x^2}{2} \right)_{\frac{1}{2}}^1 \\ &= 1 \\ f_X(x) &\text{ is a prob. density fn.} \\ F_X(x) &= \int_{-\infty}^x f_X(t)dt \end{aligned}$$

Now let us consider the following function. $f(x) = 4x$ over the interval $0 \leq x \leq 1/2$. $f(x) = 4(1-x)$ over the interval $1/2 \leq x \leq 1$ and 0 otherwise. So we have drawn the graph here over the interval 0 , it is given by this. Over the interval 0 to $1/2$, it is given by the straight line $y = f(x) = 4x$. Okay, over the interval $1/2$ to 1 , it is given by this straight line, $4(1-x)$.

So this is $4x$, $f(x) = 4x$ and this is $f(x) = 4(1-x)$, okay. Now we have to show that it is a probability density function. First of all, let us note that $f(x)$ is greater than or equal to 0 for all x belonging to $-\infty$ to ∞ , okay. The graph of $f(x)$ lies above the x axis. On the negative side of x axis, it is 0 everywhere. On the positive side of x axis, after 1 , okay, it is 0 and over 0 to 1 , it takes non-negative values.

So it is greater than or equal to 0 for all x . Now it is a probability density function provided we prove that integral over $-\infty$ to ∞ $f(x)dx = 1$, okay. So over $-\infty$ to 0 , it is 0 . Over 1 to ∞ , it is 0 . So we can write it as integral over 0 to 1 $f(x)dx$ which is equal to integral over 0 to $1/2$. Over 0 to $1/2$, it is $4x$ and then over $1/2$ to 1 , it is $4(1-x)$, okay. So we can integrate this $4 \cdot \frac{x^2}{2} \Big|_0^{1/2} + 4 \cdot \left(x - \frac{x^2}{2} \right) \Big|_{1/2}^1$.

We can substitute the limit and we shall see that it comes out to be 1 . Otherwise also we can see, from the geometry also we can find the integral over $-\infty$ to ∞ $f(x)dx$. This is integral over 0 to 1 $f(x)dx$. That means the area bounded by this triangle, okay, integral over 0 to 1 $f(x)dx$ is the area bounded by the triangle.

And this area is how much? $\frac{1}{2} \cdot \text{base} \cdot \text{height}$, area of the triangle. So this will be $\frac{1}{2}$, base $= 1$ and height is at $x = 1/2$, okay. At $x = 1/2$, we can see it is, $f(x) = 4x$. So at $x = 1/2$, the height is 2 , okay. So this is equal to 1 , okay. So area of the triangle is integral over 0 to 1 $f(x)dx$ which is equal to integral over $-\infty$ to ∞ $f(x)dx$. So $f(x)$ is a probability density function, okay. Now let us find its cumulative distribution function.

So cumulative distribution function is $F(x)$ and it is given by integral over $-\infty$ to x $f(x)dx$, okay. So first we consider the case when $x < 0$. When $x < 0$, $f(x)$ is 0 . So this probability density

function assumes value is 0. So cumulative distribution function is also 0, okay.

(Refer Slide Time: 17:14)

$$\begin{aligned}
 F_X(x) &= 0, \text{ if } x < 0 \\
 F_X(x) &= \int_{-\infty}^x f_X(x) dx, \text{ } 0 \leq x \leq \frac{1}{2} \\
 &= \int_{-\infty}^0 f_X(x) dx + \int_0^x f_X(x) dx \\
 &= 0 + \int_0^x 4x dx = (2x^2)_0^x = 2x^2 \\
 F_X(x) &= \int_{-\infty}^x f_X(x) dx, \text{ } \frac{1}{2} < x \leq 1 \\
 &= \left(\int_{-\infty}^0 + \int_0^{1/2} + \int_{1/2}^x \right) f_X(x) dx \\
 &= 0 + \int_0^{1/2} 4x dx + \int_{1/2}^x 4(1-x) dx \\
 &= (2x^2)_0^{1/2} + 4 \left(x - \frac{x^2}{2} \right)_{1/2}^x = 2 \times \frac{1}{4} + 4 \left(x - \frac{x^2}{2} - \frac{1}{2} + \frac{1}{8} \right) \\
 F_X(x) &= 4x - 2x^2, \text{ } \frac{1}{2} < x \leq 1
 \end{aligned}$$

So $F_X(x)=0$ if $x<0$, okay. Then let us consider the case when 0 is less than or equal to $x<1/2$, okay.

So we consider the case 0, suppose x is greater than or equal to 0 but less than $1/2$, okay. So we can assume, this is equal to, in fact all of $x=1/2$ also we can take. So we will have integral over $-\infty$ to x , that means $-\infty$ to 0 $f_X(x)dx$ + integral over 0 to $1/2$ $f_X(x)dx$, okay. So this is equal to 0 because over $-\infty$ to 0 $f_X(x)$ is 0 and then 0 to $1/2$, it is given by $4x$, okay.

So this is $2x^2$. So 0 to, oh it is x , okay. Let me not $1/2$. So we can write it as 0 to x , not $1/2$, okay. So this will be $2x^2$ 0 to x that is $2x^2$, okay. Then $f_X(x)=-\infty$ to x $f_X(x)dx$. Let us find $f_X(x)$. When $x>1/2$ and less than or equal to 1. So $1/2 < x$ less than or equal to 1, okay. Then we have $-\infty$ to 0 0 to $1/2$ and then $1/2$ to x , okay, $f_X(x)dx$. So we shall have here, integral over $-\infty$ to 0 $f_X(x)dx$ will be 0 because the function $f_X(x)$ is 0.

Then 0 to $1/2$, $f_X(x)dx$. 0 to $1/2$, $f_X(x)$ is $4x$. So $4x dx$. Then $1/2$ to 1, $1/2$ to x . $f_X(x)$ is $4*1-x$, okay. So we will get this as, this is $2x^2$ 0 to $1/2$ and here we will get $4*x - x^2/2$ $1/2$ to x , okay. So this is $2*1/4 + 4*x - x^2/2 - 4*1/2 - 1/2^2$, that is $1/4/2$, that is $1/8$, okay. So how much it will be? This is equal to $1/2$, okay, $+4x - 2x^2$ and what we get here? $1/2 - 1/8$ is or we can multiply by 4. So -2 , okay, and $+1/2$. So what do we get?

This is $1/2$, $1/2$ is 1 , $1-1$, so $4x-2x^2-1$, okay. So when x lies in this interval, okay, $f_{xx}=4x-2x^2-1$, okay. So $4xf_{xx}=4x-2x^2-1$, provided $1/2 < x \leq 1$. And when $x > 1$, okay.

(Refer Slide Time: 21:35)

when $x > 1$ then

$$F_X(x) = \int_{-\infty}^x f_X(t) dt$$

$$= \left(\int_{-\infty}^0 + \int_0^{1/2} + \int_{1/2}^1 + \int_1^x \right) f_X(t) dt$$

$$= 0 + 1 + 0 = 1$$

Thus, we have

$$F_X(x) = \begin{cases} 0, & x < 0 \\ 2x^2, & 0 \leq x \leq \frac{1}{2} \\ 4x - 2x^2 - 1, & \frac{1}{2} < x \leq 1 \\ 1, & x > 1 \end{cases}$$

Now let us consider the case when $x > 1$, okay. Then $f_{xx} = \text{integral over } -\infty \text{ to } x f_{xx} dx = \text{integral over } -\infty \text{ to } 0, \text{ okay, } + \text{integral over } 0 \text{ to } 1/2 + \text{integral over } 1/2 \text{ to } 1, \text{ okay, } + \text{integral over } 1 \text{ to } x f_{xx} dt, \text{ okay. So this is equal to integral over } -1/2 \text{ to } 0, \text{ it is } 0. \text{ Then integral over } 0 \text{ to } 1/2 + \text{integral over } 1/2 \text{ to } 1, f_{xx} \text{ we have found is equal to } 1. \text{ So we have } 1 + \text{integral over } 1 \text{ to } x, \text{ okay.}$

Integral over 0 to $1/2 + \text{integral over } 1/2 \text{ to } 1$, this is integral over 0 to $1/2 + \text{integral over } 1/2 \text{ to } 1 f_{xx} dt = 1$. And integral over 1 to $x f_{xx} dt = 0$ because that is 0 , okay. f_{xx} is 0 for $x > 1$. So $f_{xx} = 1$ when $x > 1$. So thus we have $f_{xx} = 0$ when $x < 0$. And we have $f_{xx} = 2x^2$ square when x is lying between 0 and $1/2$. And then we have $4x - 2x^2 - 1$ when $1/2 < x \leq 1$ and 1 when $x > 1$. So this is how we find the cumulative distribution function, okay.

(Refer Slide Time: 23:35)

Expectation and variance

Let X be a random variable with probability density function $f_X(x)$. If g is a function of X , then the expectation of $g(X)$ denoted by $E[g(X)]$ is defined as

$$E[g(X)] = \int_{-\infty}^{\infty} g(x)f_X(x)dx.$$

Thus the mean of X or equivalently expectation of X is given by

$$E(X) = \int_{-\infty}^{\infty} xf_X(x)dx$$

$$E(X^2) = \int_{-\infty}^{\infty} x^2 f_X(x)dx$$

$$\text{Var}(X) = E(X^2) - (E(X))^2$$

Now we go to the definition of expectation and variance. Let X be a random variable with probability density function $f_X(x)$. If g is a function of X , then the expectation of gX denoted by EgX is defined as $EgX = \int_{-\infty}^{\infty} gxf_X(x)dx$. The mean of f_X or equivalently the expectation of X is given by $\int_{-\infty}^{\infty} Xf_X(x)dx$.

And expectation of X square is similarly defined $\int_{-\infty}^{\infty} x^2 f_X(x)dx$. Now variance of X we know. Variance of X is expectation of x square - expectation of X whole square. So this is how we can determine variance of X once we have the values of EX and EX square.

(Refer Slide Time: 24:28)

Example 3

The demand X for a certain commodity is a random variable and has the following

$$\text{probability density function } f_X(x) = \begin{cases} \frac{1}{10} & 70 < x < 80 \\ 0 & \text{otherwise} \end{cases}$$

$$\begin{aligned} f_X(x) &\geq 0, \quad \int_{-\infty}^{\infty} f_X(x) dx = \int_{70}^{80} \frac{1}{10} dx = 1 \quad \text{Var}(X) = \frac{1690}{3} - (75)^2 = \frac{1690}{3} - 5625 = \frac{1690 - 16875}{3} = \frac{-15185}{3} \\ E(X) &= \int_{-\infty}^{\infty} x f_X(x) dx = \int_{70}^{80} x \cdot \frac{1}{10} dx = \frac{1}{10} \left(\frac{x^2}{2} \right)_{70}^{80} = \frac{1}{20} (80^2 - 70^2) \\ E(X^2) &= \int_{-\infty}^{\infty} x^2 f_X(x) dx = \int_{70}^{80} x^2 \cdot \frac{1}{10} dx = \frac{1}{10} \left(\frac{x^3}{3} \right)_{70}^{80} = \frac{1}{30} (80^3 - 70^3) \\ &= \frac{1}{30} (512000 - 343000) = \frac{169000}{30} = \frac{16900}{3} \end{aligned}$$

MIT

MIT ONLINE
CERTIFICATION COURSE

11

Now let us consider this question. The demand X for a certain commodity is a random variable and has the following probability density function $f_X(x) = 1/10$ $70 < x < 80$ and 0 otherwise. We can find here, we can see that integral over $-\infty$ to ∞ $f_X(x) dx = \int_{70}^{80} 1/10 dx$, okay. This is equal to 1, okay. And also that $f_X(x)$ is greater than or equal to 0. So that we can see here, it takes non-negative values, okay.

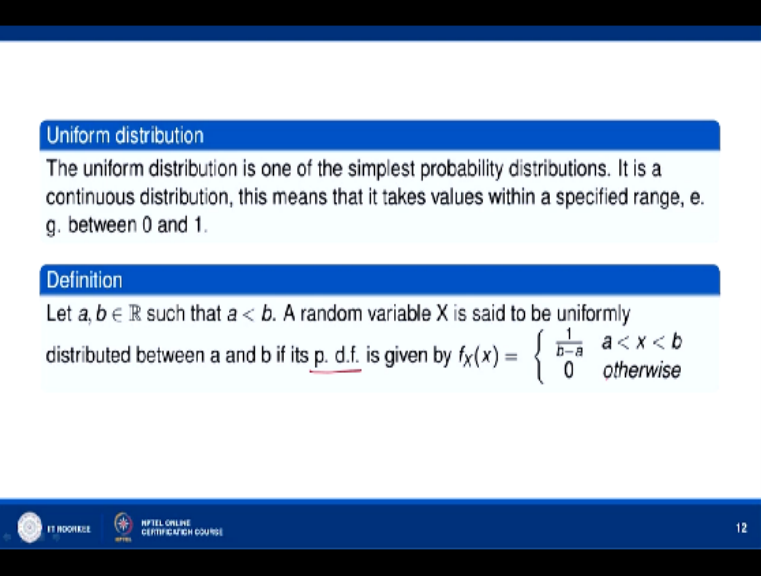

So $f_X(x)$ is a probability density function. We can find mean here. So expectation of $x = \int_{-\infty}^{\infty} x f_X(x) dx$. So this will be integral over 70 to 80 $x \cdot 1/10 dx$. And this will be equal to $1/10 \cdot x^2/2$ 70 to 80. So we can find here, this is $1/20$ and then we have $80^2 - 70^2$, okay. So this is equal to $1/20 \cdot (80^2 - 70^2)$, okay. So this is $1/20 \cdot (6400 - 4900) = 1/20 \cdot 1500 = 75$, okay.

So we have 75, okay. So expectation is 75. Expectation of x^2 if you find, this will be equal to integral over $-\infty$ to ∞ $x^2 f_X(x) dx$ and this will be equal to integral over 70 to 80 $1/10$ that is $f_X(x) \cdot x^2 dx$. So this is $1/10 \cdot x^3/3$, okay, 70 to 80. So this is $1/30 (80^3 - 70^3)$, okay. So this is $1/30$, then we have, we can factorize this. So $80^3 - 70^3$ is $a^3 - b^3$, that is $a - b$ is 10, $a^2 + ab + b^2$, so $80^2 + 80 \cdot 70 + 70^2$, okay.

So this will give you, equal to, this is 80^2 is 6400 + 4900 + $80 \cdot 70$, 5600, /3, okay. So this will come out to be 16900, /3, okay. So this is $E(X^2)$.

Now once we have EX square, we can subtract from EX square EX whole square to get the variance of X . So variance of X will be equal to EX square that is $16900/3-75$ whole square and we get the variance of X , okay. So we can calculate the variance of X here and from that variance of X , we can find the value of standard deviation also, okay.

(Refer Slide Time: 28:20)

Uniform distribution

The uniform distribution is one of the simplest probability distributions. It is a continuous distribution, this means that it takes values within a specified range, e.g. between 0 and 1.

Definition

Let $a, b \in \mathbb{R}$ such that $a < b$. A random variable X is said to be uniformly distributed between a and b if its p. d.f. is given by $f_X(x) = \begin{cases} \frac{1}{b-a} & a < x < b \\ 0 & \text{otherwise} \end{cases}$

ET ROOPEE MPTEL ONLINE CERTIFICATION COURSE 12

Now let us go to uniform distribution. The uniform distribution is one of the simplest probability distributions. It is a cumulative distribution. This means that it takes values within a specified range, that is between 0 and 1, okay. So let us take a and b to be any 2 real numbers such that $a < b$, okay. As a random variable X is called uniformly distributed between a and b if its probability density function is given by $1/b-a$ $a < x < b$ and 0 otherwise. We can draw its graph.

(Refer Slide Time: 28:54)

For the case $a < 0 < b$, the graph of the p.d.f. as shown in the figure:

Fig1

$$F_X(x) = \int_{-\infty}^x f_X(x) dx = 0, \quad x < a$$

$$= \int_a^x f_X(x) dx = \int_a^x \frac{1}{b-a} dx = \frac{x-a}{b-a}, \quad a \leq x \leq b$$

$$F_X(x) = 1, \quad x > b$$

NPTEL ONLINE
CERTIFICATION COURSE

13

Suppose $a < 0 < b$, then the graph of the probability density function of the normal uniform distribution is given by this, okay. Between a to b , it takes values $1/b-a$, elsewhere it takes values 0. The area under the graph of f_X , you can see is $1/b-a \cdot b-a$. So equal to 1. The area bounded by the rectangle is 1, okay.

(Refer Slide Time: 29:21)

The distribution function

$$F_X(x) = \begin{cases} 0 & x < a \\ \frac{x-a}{b-a} & a \leq x \leq b \\ 1 & x > b \end{cases}$$

NPTEL ONLINE
CERTIFICATION COURSE

14

Now the distribution function, we can see here, the distribution function $F_X(x)$. We know its definition is $-\infty$ to x $f_X(x) dx$ integral over $-\infty$ to x $f_X(x) dx$ and this will be equal to 0 if $x < a$, okay. If $x < a$, okay, so this will be 0. If x is less than or equal to x less than or equal to b , so this will be equal to integral over a to x $f_X(x) dx$. Because over $-\infty$ to a , $f_X(x)$ is 0. So this will be equal to integral over a to x , okay, $1/b-a \cdot dx$ and this will be equal to $x-a/b-a$, okay.

So over the interval a less than or equal to x less than or equal to b it is $x-a/b-a$. And when $x > b$, okay, $f(x)=1$, okay. So we have this cumulative distribution function and we can see its graph when $x < a$, it is 0. When x lies between a and b , it is given by this straight line $x-a/b-a$. So this is $f(x)=x-a/b-a$. And here, $f(x)=1$, okay. So this is the graph of cumulative distribution function of an uniform distribution.

(Refer Slide Time: 31:10)

Since the shape of the curve in Fig 1 is rectangular, it is also called a rectangular distribution. It is called a uniform distribution because the p.d.f is constant over (a, b) , the interval in which the random variable takes its values. We apply this distribution if the random variable is equally likely to take any of the possible values in an interval.

Here, $E(X) = \frac{a+b}{2}$, $E(X^2) = \frac{(a^2+b^2+ab)}{3}$. Hence $\text{Var}(X) = \frac{(a-b)^2}{12}$.

Now, consider the example 3. Hence X is uniformly distributed, so $E(X) = 75$ and $\text{Var}(X) = \frac{25}{3}$.

$E(X) = \int_{-\infty}^{\infty} x f_X(x) dx = \int_a^b x \frac{1}{b-a} dx = \frac{1}{b-a} \left(\frac{x^2}{2} \right)_a^b = \frac{b^2 - a^2}{2(b-a)}$
 $E(X^2) = \int_{-\infty}^{\infty} x^2 f_X(x) dx = \int_a^b x^2 \frac{1}{b-a} dx = \frac{1}{b-a} \left(\frac{x^3}{3} \right)_a^b = \frac{b^3 - a^3}{3(b-a)}$
 $\text{Var}(X) = E(X^2) - (E(X))^2 = \frac{b^3 - a^3}{3(b-a)} - \left(\frac{b^2 - a^2}{2(b-a)} \right)^2 = \frac{(b-a)^2}{12}$

$E(X) = \frac{10+80}{2} = 75$
 $\text{Var}(X) = \frac{10^2 - 80^2}{12} = \frac{60^2}{12} = \frac{3600}{12} = 300$

NPTEL ONLINE CERTIFICATION COURSE

15

Now you can see the shape of the curve in this one is rectangular, okay. This curve is said, here it is rectangular shape. So that is why rectangular, this uniform distribution is also called a rectangular distribution, okay. It is called uniform distribution because probability density function is constant over interval ab the interval in which the random variable takes its values.

We apply this distribution if the random variable is equally likely to take any of the possible values in an interval. $EX = a+b/2$ as we have just now calculated EX in this case of this example. In the case of this example. Similarly, we can calculate the EX for the case of uniform distribution. So EX will be equal to integral over $-\infty$ to ∞ $x \cdot f(x) dx$. So this will be equal to integral over a to b , okay, $x \cdot f(x)$ integral over a to b $f(x)$ is $1/b-a$, okay.

So this will be equal to $1/b-a$ $x^2/2$ a to b and this will be $b^2/2 - a^2/2$. So this is $b^2 - a^2/2$. Similarly, if we calculate EX^2 . EX^2 will be integral over $-\infty$ to ∞ x^2

square $fx dx$. This is equal to integral over a to b of $x^2/b - ax$. And this will be equal to $1/b \cdot ax^3/3$. So it is a to b , so this is $1/b \cdot ab^3/3 - a^3/3$. So this is $b^3/3 + a^3/3$, okay. We get this formula.

And then we can calculate variance of X from this formula, $EX - EX$ whole square, okay. So we can apply this formula and we will get variance of X to be equal to $(b-a)^2/12$ okay. Now we can consider the example a , okay, this example, this one, okay. So we can consider in this example, we have been given the values of a and b , a is 70 b is 80, okay. So we can put these values.

$a=70$ $b=80$, then EX is 75 and when you put here $a=70$ $b=80$, then $80-70$, 10, 10, 100 square, 100 square/12, so variance of $X=$, $EX=70+80/2$, meaning that it is 75. And variance of X will be equal to $70-80$, that is 100 square/12. So 100/12, which means that it is 25/3, okay. So that is the variance of X , okay. Now let us go to this example.

(Refer Slide Time: 34:49)

Example 4

Suppose a man is about to take an elevator to go to his flat in a building. Once he calls the elevator, suppose it takes between 0 and 40 seconds to arrive to him. Assuming that the elevator arrives uniformly between 0 and 40 seconds after the man presses the button. Determine the probability that the elevator takes less than 15 seconds to arrive to the man. Also find the expected time of arrival and the variance.

$$E(X) = \frac{0+40}{2} = 20$$

$$Var(X) = \frac{(a-b)^2}{12} = \frac{(40)^2}{12} = \frac{1600}{12} = \frac{400}{3}$$

$$P(X \leq 15) = \int_{-\infty}^{15} f_X(x) dx$$

$$= \int_0^{15} \frac{1}{40} dx = \frac{x}{40} \Big|_0^{15} = \frac{15}{40} = \frac{3}{8}$$

$$f_X(x) = \begin{cases} \frac{1}{40}, & 0 \leq x \leq 40 \\ 0, & \text{otherwise} \end{cases}$$

NPTEL ONLINE
CERTIFICATION COURSE

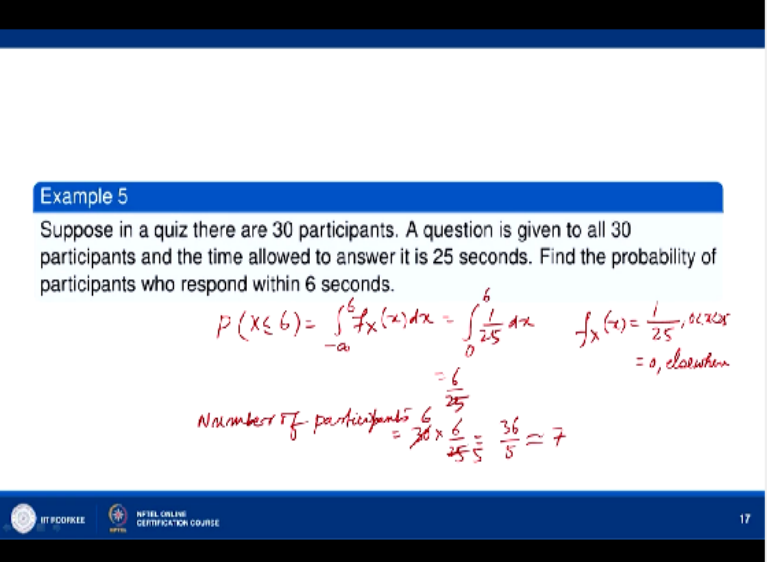

18

Suppose a man is about to take an elevator to go to his flat in a building. Once he calls the elevator, suppose it takes between 0 and 40 seconds to arrive to him, okay. Assuming that the elevator arrives uniformly between 0 and 40 seconds after the man presses the button. Determine the probability that the elevator takes less than 15 seconds to arrive to the man, okay. So this is uniform distribution here.

So we have to find the probability that X is less than or equal to 15, okay. The f_{xx} is given by $1/b-a$. So $1/b-a$ means $1/40-0$. So $1/40$ when $0 < x < 40$, okay and 0 otherwise, okay. $0 < x$ less than or equal to 40, it is $1/40$ and 0 otherwise, so this will be equal to integral over $-\infty$ to 15, okay, $f_{xx} dx$. So this will be equal to integral over 0 to 15 f_{xx} , that is $1/40 dx$, okay. So $15/40$ which means that $3/8$, okay.

Also find the expected time of arrival and variance. Expectation of X will be equal to as we have just now seen, expectation of $X = a+b/2$. $a+b/2$ means $0+40/2$, okay. that means 20. And variance of X we have just now seen. Variance of $X = a-b$ whole square/12, okay. So a is 0, b is 40. So 40 square/12. So this means $1600/12$, okay. So this is $400/3$, okay. That is the variance.

(Refer Slide Time: 37:06)

Example 5
 Suppose in a quiz there are 30 participants. A question is given to all 30 participants and the time allowed to answer it is 25 seconds. Find the probability of participants who respond within 6 seconds.

$$P(X \leq 6) = \int_{-\infty}^6 f_X(x) dx = \int_0^6 \frac{1}{25} dx \quad f_X(x) = \frac{1}{25}, 0 \leq x < 25$$

$$= \frac{6}{25}$$

Number of participants = $30 \times \frac{6}{25} = \frac{36}{5} = 7.2$

NPTEL ONLINE CERTIFICATION COURSE

Now let us suppose in a quiz there are 30 participants. A question is given to all 30 participants and the time allowed is 25 seconds. Find the probability of participants who respond within 6 seconds, okay. So we have to find the probability that X is less than or equal to 6, okay. So this is integral over $-\infty$ to 6, okay, $f_{xx} dx$, okay. So this is integral over 0 to 6, okay, f_{xx} is $1/25$, okay, dx .

So this is $6/25$, okay. So here the f_{xx} is given by $1/b-a$ that is $1/25$, okay, $0 < x < 25$ and 0 elsewhere. The number of participants, okay, find the number of participants who respond within 6 seconds.

So number of participants = $30 \times 6/25$, that means $36/5$. So that is approximately 7. So number of participants who respond within 6 seconds is 7, okay.

(Refer Slide Time: 38:40)

Example 6

Metro trains run on a certain line every half hour between midnight and six in the morning. What is the probability that a man entering the station at a random time during this period will have to wait at least 20 minutes?

let X denote the waiting time of the man for the metro train

Then $P(20 \leq X \leq 30) = \int_{20}^{30} f_X(x) dx$

$= \int_{20}^{30} \frac{1}{30} dx = \frac{10}{30} = \frac{1}{3}$

$f_X(x) = \begin{cases} \frac{1}{30-0}, & 0 \leq x < 30 \\ 0, & \text{elsewhere} \end{cases}$

NPTEL ONLINE CERTIFICATION COURSE
19

Now let us see metro trains run on a certain line every half hour between midnight and 6 in the morning. What is the probability that a man entering the station at a random time during this period will have to wait at least 20 minutes? So let us say let X denote the waiting time for the metro train, okay. Let X denote the waiting time of the man for the metro train, okay. Then probability that he has to wait at least 20 minutes.

So X varies between 20 less than or equal to x less than or equal to 30 because every half hour there is a train. So integral over 20 to 30, okay, $\int_{20}^{30} f_X(x) dx$, okay. Now $f_X(x) = 1/(b-a)$. $1/30-0$, because every half hour there is a train, so $30-0$, $0 < x < 30$ and 0 elsewhere. So this will be $\int_{20}^{30} 1/30 dx$ and it will be equal to $10/30$, that means $1/3$. So probability that the man will have to wait at least 20 minutes is $1/3$. So this is where I would like to end my lecture. Thank you very much for your attention.
