Lecture - 49
Poisson Process

Hello friends. Welcome to my lecture on Poisson Process. The Poisson Process is one of the most widely used counting process. It is used when we want to count the occurrences of certain events that appear to happen at a certain rate but completely at random.

(Refer Slide Time: 00:49)

Poisson Process

The Poisson process is one of the most widely-used counting process. It is used when we count the occurrences of certain events that appear to happen at a certain rate, but completely at random.

For example, the number of car accidents in an area, the location of users in a wireless network, the request for individual documents on a web server etc.

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 2

For example, the number of car accidents in area the location of users in a wireless network, the request for individual documents on a web server etc.

Poisson Process Cont...

Consider a random process representing the number of occurrences of an event up to time t (over the time interval $(0, t)$). Such a process is called a counting process and we denote it by $\{N(t), t \geq 0\}$. Clearly $\{N(t), t \geq 0\}$ is continuous time discrete state process and any of its realization is non decreasing function of time. The counting process is called a Poisson process with the rate parameter λ if

Figure : Fig.1

Consider a random process representing the number of occurrences of an event up to time t that is over the time interval $0, t$. Such a process is called a counting process and we denote it by $N(t)$ $t \geq 0$. Clearly $N(t)$ $t \geq 0$ is continuous time discrete state process and any of its realization is non decreasing function of time as time increases the value of $N(t)$ increases, so it is non-decreasing function of time. The counting process is called a Poisson process with the rate parameter λ if it satisfies the following conditions.

(Refer Slide Time: 01:35)

Poisson Process Cont...

First definition

- i) $N(0) = 0$,
- ii) $N(t)$ is an independent increment process i.e. the number of occurrences in two non overlapping time intervals are independent.
Thus from Figure (1), the increments $N(t_2) - N(t_1)$ and $N(t_4) - N(t_3)$ are independent,
- iii) The number of occurrences in any interval of length $\tau > 0$ has Poisson (λ, τ) distribution.

$N(0)=0$ that is at time $= 0$, okay. $N(t)=0$, $N(t)$ is an independent increment process that is the number of occurrences in two non overlapping time intervals are independent. Thus from figure 1 we can see that, in the figure 1 we are; the times are indicated, time $t=0$ then $t=1$, $t=2$, $t=3$ and

$t=t_4$. So in the time interval t_1 to t_2 the increments $N(t_2) - N(t_1)$ and in the time interval t_3 to t_4 the increment $N(t_4) - N(t_3)$ are independent, okay.

So in two non overlapping intervals the number occurrences are independent. The number of occurrences in any intervals of length $\Delta t > 0$ follows a $\lambda \Delta t$ distribution.

(Refer Slide Time: 02:33)

Second definition of Poisson Process

(i) and (ii) are same as in first definition

(iii) $P\{N(\Delta t) = 0\} = 1 - \lambda \Delta t + o(\Delta t)$

(iv) $P\{N(\Delta t) = 1\} = \lambda \Delta t + o(\Delta t)$,

where $o(\Delta t)$ implies any function such that $\lim_{\Delta t \rightarrow 0} \frac{o(\Delta t)}{\Delta t} = 0$

(v) $P\{N(\Delta t) \geq 2\} = o(\Delta t)$

These assumptions are valid for many applications.

Now there is second definition of this Poisson process. In the second definition 1 and 2 are same thus, $N(0)=0$ and $N(t)$ is an independent increment process that also occurs in the second definition. But the third condition, okay is replaced by these one, $P\{N(\Delta t) = 0\} = 1 - \lambda \Delta t + o(\Delta t)$, $P\{N(\Delta t) = 1\} = \lambda \Delta t + o(\Delta t)$ where $o(\Delta t)$ implies any function of Δt such that $\lim_{\Delta t \rightarrow 0} \frac{o(\Delta t)}{\Delta t} = 0$.

Then, $P\{N(\Delta t) \geq 2\} = o(\Delta t)$, okay. So these assumptions are valid for many applications. So there are two definitions and this is definition 1, okay this is definition 2.

(Refer Slide Time: 03:30)

Examples 1

- 1 Number of alpha particles emitted by a radio active substance.
- 2 Number of cars arriving at a petrol pump during a particular interval of time.
- 3 Number of trucks arriving at a check post.
- 4 Number of incoming telephone calls at an exchange.

Now let us see some examples on Poisson process, number of alpha particles emitted by a radioactive substance; number of cars arriving at a petrol pump during a particular interval of time; number of trucks arriving at a check post; number of incoming telephone calls at an exchange.

(Refer Slide Time: 03:51)

Probability mass function for the Poisson Process

Figure : Fig.2

Consider the time interval $(t, t + \Delta t)$ in Fig.2 Then
 $P(\{N(t + \Delta t) = n\}) = \text{Probability of occurrence of } n \text{ events up to time } (t + \Delta t)$

Probability mass function for the Poisson Process, so let us find the probability mass function for the Poisson process. This figure shows the time t and time $t + \Delta t$, so consider the time interval t to $t + \Delta t$ in this figure, okay. Then $P\{N(t + \Delta t) = n\}$, $P\{N(t + \Delta t) = n\}$ means over the time period time interval 0 to $t + \Delta t$ number of occurrences = n . The probability of $N(t + \Delta t) = n$ is probability of a occurrences of n events up to time $t + \Delta t$.

(Refer Slide Time: 04:28)

Probability Mass Function for the Poisson Process cont...

$$\begin{aligned}
 P(\{N(t + \Delta t) = n\}) &= P(\{N(t) = n, N(\Delta t) = 0\}) + P(\{N(t) = n-1, N(\Delta t) = 1\}) + P(\{N(t) < n-1, N(\Delta t) \geq 2\}) \\
 &= P(\{N(t) = n\})P(\{N(\Delta t) = 0\}) + P(\{N(t) = n-1\})P(\{N(\Delta t) = 1\}) + P(\{N(t) < n-1\})P(\{N(\Delta t) \geq 2\}) \\
 &= P(\{N(t) = n\})(1 - \lambda \Delta t + o(\Delta t)) + P(\{N(t) = n-1\})(\lambda \Delta t + o(\Delta t)) + P(\{N(t) < n-1\})o(\Delta t)
 \end{aligned}$$

Handwritten notes on the slide include:

- On the left side, a derivation for the left-hand side (LHS) of the equation:

$$\begin{aligned}
 \text{LHS} &= P(\{N(t + \Delta t) = n\}) \\
 &= \frac{P(\{N(t + \Delta t) = n\}) - P(\{N(t) = n\})}{\Delta t} \\
 &= \frac{-\lambda \Delta t P(\{N(t) = n\}) + o(\Delta t) P(\{N(t) = n\}) + \lambda \Delta t P(\{N(t) = n-1\}) + P(\{N(t) < n-1\})o(\Delta t)}{\Delta t} \\
 &\Rightarrow \frac{P(\{N(t + \Delta t) = n\}) - P(\{N(t) = n\})}{\Delta t} = -\lambda P(\{N(t) = n\}) + \frac{o(\Delta t)}{\Delta t} P(\{N(t) = n\})
 \end{aligned}$$
- On the right side, a derivation for the right-hand side (RHS) of the equation:

$$\begin{aligned}
 \text{RHS} &= P(\{N(t) = n\})P(\{N(\Delta t) = 0\}) + P(\{N(t) = n-1\})P(\{N(\Delta t) = 1\}) + P(\{N(t) < n-1\})P(\{N(\Delta t) \geq 2\}) \\
 &= P(\{N(t) = n\})(1 - \lambda \Delta t + o(\Delta t)) + P(\{N(t) = n-1\})(\lambda \Delta t + o(\Delta t)) + P(\{N(t) < n-1\})o(\Delta t)
 \end{aligned}$$

So $P(N(t + \Delta t) = n)$ can be written as $P(N(t) = n, N(\Delta t) = 0)$. This n occurrences in the time interval 0 to $t + \Delta t$ may occur during the time 0 to t and then there is no occurrence between t and $t + \Delta t$, okay. The other situation can be that during the time period 0 to t number of occurrences are $n-1$ and from t to $t + \Delta t$ there is one occurrence. Then, third situation is number of occurrences in the time interval 0 to $t < n-1$. And between t and $t + \Delta t$ number of occurrences is more than or equal to 2 . So there can be three such possibilities, okay.

Now, probability $N(t) = n$, and $\Delta t = 0$ since we have assumed that the time intervals the; we have assumed that $N(t)$ is an independent increment process that is number of occurrences in two non overlapping intervals are independent, okay. So probability of since $N(t) = n$ and $\Delta t = 0$ are independent events so probability of $N(t) = n$ $\Delta t = 0$ will be = product of their probabilities so probability of $N(t) = n$ probability and $\Delta t = 0$.

Similarly, for the second possibility case, probability $N(t) = n-1$ probability $N(t) = 1$ and $\Delta t = 1$. Then third possibility is probability that $N(t) < n-1$ probability that $N(\Delta t) \geq 2$, okay. So this is because as I said this is because the $N(t) = n$ and $\Delta t = 0$ these events are independent. Now probability $N(t) = n * \text{probability } n \Delta t = 0$; $n \Delta t = 0$ for probability that $n \Delta t = 0$ it is we have $1 - \lambda \Delta t + \text{small order } \Delta t$. So let us put that here.

(Refer Slide Time: 07:17)

Now let us find the limit, okay. Limit of $P_N(t + \Delta t) - P_N(t) / \Delta t$. Let us see how we get this. So if you multiply on the right side what you get? Right side is equal $P_N(t) N^{t=N} * 1$ so $P_N(t) - \lambda \Delta t P_N(t)$, okay + small order $\Delta t * P_N(t)$, okay. Then here what we have, $P_N(t-1) * \lambda \Delta t$ and then $P_N(t-1) * \Delta t^0$; small order Δt , okay. And then $P_N(t) N^{t < N-1} * \text{small order } \Delta t$, okay.

Now this term, okay this term we can subtract on the left side and that divide by Δt . So what we will get? $P(N, t + \Delta t) = n$ – we subtract this value $P(N, t) = n$, okay. And then divide by Δt . So what do we get then? $-\lambda P(N, t) + \text{small order } \Delta t / \Delta t * P(N, t) = n$, okay. Plus this value $\lambda \Delta t P(N, t - 1)$ is divided by Δt and we have $+\lambda$ times, we are dividing by Δt so $P(N, t - 1)$ and then we have $P(N, t - 1) * \text{small order } \Delta t / \Delta t$ and then we have $P(N, t - 1) * \text{small order } \Delta t / \Delta t$. Okay.

Now as Δt goes to 0, okay. As Δt goes to 0 small order Δt over Δt goes to 0. So let us use this. So as Δt goes to 0, okay we have small order $\Delta t / \Delta t$ goes to 0, okay. So what will happen, this term okay this term will go to 0; this term will go to 0 and this term will go to 0, okay because $P(N, t=n) P(N, t=n-1) P(N, t < n-1)$ are finite quantities they are probabilities so they lie between 0 and 1, okay.

So they will go to 0 and therefore, as Δt goes to 0 $P(N, t+\Delta t) - P(N, t) / \Delta t$ will go to $-\lambda P(N, t) + \lambda P(N, t-1)$, so we get; λ we can take common, $-\lambda$ we can take common then we will have $P(N, t) - P(N, t-1)$. So as Δt goes to 0 we get this, okay. Now by definition of derivative the left hand side denotes d/dt of $P(N, t)$. So d/dt of $P(N, t) = \lambda P(N, t-1) - \lambda P(N, t)$.

You can see this is the first order linear differential equation, okay with the initial condition $P(N=0, t=0) = 1$, because we have this condition with us $N(0)=0$, okay. So probability of $N(0)=0$, okay. So probability of $N(0)=0$ is 1 okay. So let us solve this differential equation. We can put $N=1$, okay. Let us put $N=$; let us put $N=0$ first, okay. So let us put $N=0$ in equation 1, okay in this equation. Then d/dt of $P(N=0, t)$ will be equal to $\lambda - \lambda P(N=0, t)$. $-\lambda$ probability that $N < 0$ is equal to -1, okay.

Now probability that $N(t) = -1$ is 0 because $N(t)$ is always $> \text{ or } = 0$. So this value becomes 0. So thus, what we have d/dt of $P(N=0, t) = -\lambda P(N=0, t)$. Okay. So let us say, $P(N=0, t)$ be A . Let A be equal to $P(N=0, t)$. Let us say this value is A , okay. Then $dA/dt = -\lambda A$. So we can solve it easily. So $dA/A = -\lambda dt$. This gives you $A = e^{\text{to the power } -\lambda t}$ * some constant say C , okay. $A = \text{some constant } t \text{ times } e^{\text{to the power } -\lambda t}$. When $t=0$ we put we have to find the value of A at $t=0$, okay.

So at $t=0$ probability that $N(0)=0$ is 1, okay. Probability that $N(0)=0$ is 1, okay. Probability that $N(0)=0$; when $t=0$, okay yeah and $P(t=0)$ probability that $N(0)=0$ is 1, okay so what we will get, $1=C$, okay we will get $1=C$ when you put $t=0$, we get right hand side as C and A , A is this okay at $t=0$. Since we have assumed that $N(0)=0$, so $N(0)=0$ is certain and therefore it is probability is 1, so $C=1$,

okay. So we get $A = e$ to the power $-\lambda t$, okay. So we get probability $N(t=0) = e$ to the power $-\lambda t$, okay. So this is how we solve this and this is what we get here, okay.

(Refer Slide Time: 15:40)

Probability Mass Function for the Poisson Process cont...

$P(\{N(t) = 0\}) = e^{-\lambda t}$ is the solution of this differential equation because $P(\{N(0) = 0\}) = 1$.

Next, to find $P(\{N(t) = 1\})$, we have

$$\begin{aligned} \frac{d}{dt} P(\{N(t) = 1\}) &= -\lambda [P(\{N(t) = 1\}) - P(\{N(t) = 0\})] \\ &= -\lambda [P(\{N(t) = 1\}) - e^{-\lambda t}] \end{aligned}$$

$$\frac{d}{dt} P(\{N(t) = 1\}) = -\lambda P(\{N(t) = 1\}) + \lambda e^{-\lambda t} \quad (2)$$

with the initial condition $P(\{N(0) = 1\}) = 0$,
 Then (2) $\Rightarrow P(\{N(t) = 1\}) = \lambda t e^{-\lambda t}$
 Hence by mathematical induction, $P(\{N(t) = n\}) = \frac{(\lambda t)^n e^{-\lambda t}}{n!}$

IT ROADS
NPTEL ONLINE
CERTIFICATION COURSE

10

Probability that $N(0)=0$ is 1, okay so probability that $N(t=0)$ comes out to be e to the power $-\lambda t$, okay. Now let us find probability of $N(t=1)$. So let us take $t=n$; $n=1$ here. So let us take $n=1$ here then we will get $d/dt P(N(t)=1) = -\lambda P(N(t)=1) - P(N(t)=0)$. And $P(N(t)=0)$ we have already found e to the power $-\lambda t$ so let us put its value here, so $-\lambda P(N(t)=1) - \lambda e^{-\lambda t}$, okay.

So, then what do we get d/dt of $P(N(t)=1) = -\lambda P(N(t)=1) + \lambda e^{-\lambda t}$, okay. Now let us find the; let us solve this differential equation, okay. So this is of the type; okay this is of the type let us if you take $P(N(t)=1)$ as some say B then this is $dB/dt = -\lambda B + \lambda e^{-\lambda t}$. So let us solve this.

(Refer Slide Time: 16:56)

$$\begin{aligned}
&\text{Let } P(\{N(t)=1\}) = B \\
&\text{then } \frac{dB}{dt} = -\lambda B + \lambda e^{-\lambda t} \\
&\frac{dB}{dt} + \lambda B = \lambda e^{-\lambda t} \quad (i) \\
&\text{I. F.} = e^{\lambda \int dt} = e^{\lambda t} \\
&\text{Multiplying (i) by } e^{\lambda t} \text{ and then integrating with respect to } t \\
&\text{we have} \\
&e^{\lambda t} B = \int \lambda e^{\lambda t} e^{-\lambda t} dt = \lambda t + D \\
&\text{When } t=0 \text{ then } D=B=0 \\
&\text{thus} \\
&e^{\lambda t} B = \lambda t \\
&B = \lambda t e^{-\lambda t} \\
&P(\{N(t)=1\}) = \lambda t e^{-\lambda t}
\end{aligned}$$

So let $P_{N(t)=1}$ I call as B okay. So then, $dB/dt = -\lambda B + \lambda e^{-\lambda t}$ okay. So I can write it as $dB/dt + \lambda B = \lambda e^{-\lambda t}$ okay. Now, this is a linear differential equation, okay. So integrating factor is $e^{-\lambda t}$ okay. So this is $e^{-\lambda t}$ okay. So we multiply by this integrating factor in this equation and then integrate with respect to t , okay.

So multiplying, let me call it as equation number say 1, okay multiplying 1 by $e^{-\lambda t}$ and then integrating with respect to t . We have $e^{-\lambda t} \lambda B = \lambda e^{-\lambda t} e^{-\lambda t} dt$, okay. So this is equal to $\lambda t + \text{some constant}$, let us say D , okay. Now when $t=0$, what we get? We get this as B and here this is 0, this is D so then $D=B$, okay. And when $t=0$ okay probability that $N(t)=1$, okay.

So we get $n_0=1$, probability that $n_0=1$ is equal to 0; $n_0=1$ means, because $N(t)$ is the probability that number of; $N(t)$ denote the number of occurrences in the time interval 0 to t , okay. So when $t=0$ okay probability that $n_0=1$ is 0 so $B=0$, okay. So we have $B=0$, okay. So thus, $e^{-\lambda t} \lambda B = \lambda t$ so $B = \lambda t e^{-\lambda t}$ okay. This means probability that, $N(t)=1 = \lambda t e^{-\lambda t}$. Okay.

So we get $P_{N(t)=1} = \lambda t e^{-\lambda t}$. Now we can carry on this process, okay we can take now $n=2$ and so that when $P_{N(t)=2}$ is $\lambda^2 t^2 e^{-\lambda t}$.

$\lambda t/2$ factorial, okay. So by mathematical indexation we can, we then have probability that $N(t)=n$ okay, $N(t)=n$ is $\lambda t e$ raise to the power n * e to the power $-\lambda t$ over n factorial, okay. So we prove this result, probability that $N(t)=n$ is $\lambda t e$ raise to the power n * e to the power $-\lambda t/n$ factorial.

(Refer Slide Time: 20:32)

Remark

1) The parameter λ is called the rate or intensity of the Poisson process.

It can be shown that

$$P(\{N(t_2) - N(t_1) = n\}) = \frac{(\lambda(t_2 - t_1))^n e^{-\lambda(t_2 - t_1)}}{n!}$$

Thus, the probability of the increments depends on the length of the interval $t_2 - t_1$, and not on the absolute times t_2 and t_1 .

For example, the number of occurrences in the time interval (2,4) has the same distribution as that of the number of occurrences in (10,12). Hence the Poisson process is a process with stationary increments.

Now the parameter λ here is called the rate or intensity of the Poisson process, okay. Now it can be shown that probability that $N(t_2) - N(t_1) = n$, okay. During the time interval t_1 to t_2 number of occurrences is n probability of that is equal to $\lambda(t_2 - t_1)$ to the power n * e to the power $-\lambda(t_2 - t_1)/n$ factorial. Thus, the probability of the increments depends on the length of the interval $t_2 - t_1$ and not on the absolute times t_2 and t_1 .

For example, the number of occurrences in the time interval 2, 4 as the same distribution as that of the number of occurrences in the time interval the 10 to 12, the Poisson process is the process with stationary increments, so we can say that.

(Refer Slide Time: 21:27)

Mass and variance of the Poisson process

Note that at any time $t > 0$, $N(t)$ is a Poisson random variable with the parameter λt . Therefore, $E(N(t)) = \lambda t$ and $\text{Var}(N(t)) = \lambda t$.

Remark

$N(t)$ is a random process with independent increment.

A typical realization of a Poisson process is shown in Figure (3):

Figure : Fig.3

Now, let us find the Mass and variances of the Poisson process. Note that, at any time $t > 0$ $N(t)$ is Poisson random variable with the parameter λt . We can see here. If you see this probability for $N(t) = n$ it is λt raised to the power n * e to the power $-\lambda t / n$ factorial. Okay. In the case of Poisson random variable, the probability is that probability of n successes is λ to the power n * e to the power $-\lambda / n$ factorial because λ is the mean there okay.

So here we can say that it is the Poisson random variable with the parameter λt . There the parameter λ here the parameter is λt . Now there λ is the mean here, λt is the mean and their variance is λ , here variance is λt . So we can say that, the mass and variance okay, the mean and variance of the Poisson process is given by λt and λt again, okay.

So we can say that $N(t)$ is a random process with independent increments. A typical realization of Poisson process is shown in this figure okay. Say this is 0, 0 to t_1 okay then t_1 to t_2 then t_2 to t_3 so this is during the time period 0 to t_1 it shows the number of occurrences and then t_1 to t_2 then t_2 to t_3 number of occurrences in the times of; during this period 0 to t_1 number of occurrences here then between t_1 to t_2 number of occurrences here and then, so $N(t)$ denote the number of occurrences here.

(Refer Slide Time: 23:13)

Examples 2

A petrol pump serves on the average 30 cars per hour. Find the probability that during a period of 5 minutes

- 1 no car comes to the station;
- 2 exactly 3 cars come to the station;
- 3 more than 3 cars come to the station.

Ans: (1) 0.0821, (2) 0.2138, (3) 0.2424.

Here $\lambda = \frac{30}{60} = \frac{1}{2}$
 $t = 5$
 $P(N(t)=0) = \frac{(\lambda t)^0 e^{-\lambda t}}{0!} = e^{-\lambda t} = e^{-5/2} = 0.0821$
 because
 $P(N(t)=n) = \frac{(\lambda t)^n e^{-\lambda t}}{n!}$
 $P(N(t)=3) = \frac{(\lambda t)^3 e^{-\lambda t}}{3!} = \frac{(\frac{5}{2})^3 e^{-5/2}}{3!} = \frac{125}{48} e^{-5/2} = 0.2138$
 $P(N(t)>3) = 1 - P(N(t)=0) - P(N(t)=1) - P(N(t)=2)$
 $= 1 - e^{-\lambda t} - \lambda t e^{-\lambda t} - \frac{(\lambda t)^2 e^{-\lambda t}}{2!} = 1 - e^{-5/2} - \frac{5}{2} e^{-5/2} - \frac{(\frac{5}{2})^2}{2} e^{-5/2}$

So let us consider this problem. A petrol pump serves on the average 30 cars per hour, okay. So here $\lambda = 30/60$ the intensity, okay. λ , if you see here in the Poisson process λ is what we denote λ by μ ; it is a rate parameter, okay. So rate here, in this problem rate is $30/60$ so this is $\lambda = 1/2$, okay. Now, so a petrol pump serves on the average 30 cars per hour, find the probability that during a period of 5 minutes, $t=5$. During a period of 5 minutes no cars comes to the station that means probability that $n=0$.

We have to find the probability that, during the time interval 5 minutes no car comes to the station so number of occurrences is 0. This is λt raise to the power 0 * e to the power $-\lambda t / 0$ factorial. Because, $P(N(t)=n)$ we have this formula. $P(N(t)=n) = \frac{(\lambda t)^n e^{-\lambda t}}{n!}$, okay. So here number of occurrences is 0. No car comes to the station. So this is equal to e to the power $-\lambda t$. $\lambda = 1/2$, $t=5$ so e to the power $-5/2$ which means that the answer is 0.0821. Okay.

Then exactly three cars comes to the station, so probability that $n=3$, okay. Probability that $n=3$ means λt raise to the power 3 * e to the power $-\lambda t / 3$ factorial. So this is $\lambda = 1/2$, t is 5. So $5/2$ raise to the power 3, e to the power $-5/2 / 3$ factorial. Okay. And this value is then 5 cube means 125, 125/2 cube is 8, $8*6$ is 48 * e to the power $-5/2$. So this value comes out to be 0.2138, okay.

Then probability that, more than 3 cars comes to the station yeah. So $n > 3$. Now this is equal to $1 - \text{probability that } n=0 - \text{probability that } n=1 - \text{probability that } n=2$, okay. So this is equal to $1 - e^{-\lambda t} - \lambda t e^{-\lambda t} - \frac{(\lambda t)^2}{2} e^{-\lambda t}$. So $\lambda t e^{-\lambda t}$ and here $n=2$ is $\frac{(\lambda t)^2}{2} e^{-\lambda t}$. Okay.

So this is equal to $1 - e^{-5/2} - \frac{5}{2} e^{-5/2} - \frac{5^2}{2^2} e^{-5/2}$ which comes out to be; if you calculate it, it is 0.2424. Okay. So this is a problem on Poisson process, okay which deals with the probability of the number occurrences during a time interval 0 to t. In our next lecture, we shall discuss exponential distribution which is based on the Poisson process. So with that I would like to end my lecture. Thank you very much for your attention.
