Lecture – 05
Applications to the Problems of Potential Flow - II

Hello friends, welcome to my second lecture on applications to the problems of potential flow, as we have seen in our last lecture, harmonic functions play an important role in hydrodynamics.

(Refer Slide Time: 00:43)

Two dimensional fluid flow

Harmonic functions also play an important role in hydrodynamics. To illustrate this, let us consider the two dimensional steady motion of a non-viscous fluid. Two dimensional means that the motion of the fluid is the same in all planes parallel to the xy -plane. It is therefore sufficient to consider the motion of the fluid in the xy -plane.

"Steady" means that the velocity is independent of time. Considering the complex representation of the velocity field

$$\vec{V} = P(x, y)\hat{i} + Q(x, y)\hat{j}$$

with function f , we have

$$f(z) = P(x, y) + iQ(x, y) \text{ where } i = \sqrt{-1}$$

To illustrate this point, let us consider the 2 dimensional a steady motion of a non-viscous fluid, 2 dimensional means, that the motion of the fluid is same in all planes parallel to the XY plane and therefore, it is sufficient to consider the motion of the fluid in the XY plane, by steady we mean that the velocity is independent of time now, considering the complex representation of the velocity field; velocity field is given by $v = P_{xy} * \text{unit vector } I + Q_{xy} * j$.

With the function, we have $fz = P_{xy} + iQ_{xy}$, i is iota here, $i = \sqrt{-1}$, so when you consider the complex representation of the velocity field, you get the complex function, $fz = P_{xy} + iQ_{xy}$.

(Refer Slide Time: 01:40)

Two dimensional fluid flow cont...

where $P(x, y)$ and $Q(x, y)$ are the components of the velocity in the x and y directions and the vector is tangential to the paths of the moving particles of the fluid. Such a path is called a stream line of motion.

If $z(t) = x(t) + iy(t)$ is a parametrization of the path that a particle follows in the fluid flow then the tangent vector

$$\frac{dz}{dt} = \frac{dx}{dt} + i \frac{dy}{dt}$$

to the path must coincide with $f(z(t))$.

Where P_{xy} and Q_{xy} are the components of the velocity, you can see here, P_{xy} and Q_{xy} are the components of the velocity vector v in the X and Y directions, so and the vector is tangential to the to paths of the moving particles of the fluid, such a path is called a streamline of motion. If $z = xt + iyt$ is a parameterisation of the path that a particle follows in the fluid flow then the tangent vector to this path will be given by, $dz/dt = dx/dt + i dy/dt$ must coincide with $f(z)$.

(Refer Slide Time: 02:23)

Two dimensional fluid flow cont...

Hence

$$\frac{dx}{dt} = P(x, y), \frac{dy}{dt} = Q(x, y) \quad (1)$$

The family of solutions to the system of first order differential equations (1) is called the stream lines of the planar flow associated with $f(z)$.

So, $dx/dt = P_{xy}$, okay and dy/dt will be $= Q_{xy}$, the family of solutions to the system of first order differential equations, this you can see, this is a system of first order differential equations, it is the family of the solutions of this system is called the streamline to the planar flow associated with the complex function fz .

(Refer Slide Time: 02:54)

Example 1

Let $f(z) = \bar{z} = x - iy = P(x, y) + iQ(x, y)$

then $x = c_1 e^t, y = c_2 e^{-t}$ (2)

$\Rightarrow P(x, y) = x$
 $Q(x, y) = -y$

We have
 $\frac{dx}{dt} = P(x, y) = x$
 $\frac{dy}{dt} = Q(x, y) = -y$

Now, $\frac{dx}{x} = dt \Rightarrow x = c_1 e^t$
 $\frac{dy}{y} = -dt \Rightarrow y = c_2 e^{-t}$

Now, let us consider $fz = z$ conjugate $= x - iy$, so you can see here, $x = z$ conjugate is; $z = x + iy$, so z conjugate is $x - iy$ and now, we have written $fz = Pxy + iQxy$, where as you know Pxy and Qxy are the components of the velocity in x and y directions, so comparing we get $Pxy = x$ $Qxy = -y$. Now, we know that we have $dx/dt = Pxy$ and $dy/dt = Qxy$, so $Pxy = x$ and $dy/dt = Qy$ which is $-y$.

And thus we have dx/dt , okay now, $dx/dt = x$; $dx/dt = x$ gives $dx/x = dt$, implies that $x =$ some constant times e to the power t , integrating both sides, we can see $x = c_1 e^{\text{power } t}$, similarly $dy/dt = -y$ gives $dy/y = -dt$, so this implies $y = c_2$ times e to the power $-t$, so we get when $fz = x - iy$, z conjugate, then x and y are given by $c_1 e^{\text{power } t}$ and y is given by $c_2 e^{\text{power } -t}$.

(Refer Slide Time: 04:51)

Example cont...

In order to plot the curve $z(t) = x(t) + iy(t)$, we eliminate t in (2) to obtain

$$xy = c_1 c_2 \text{ or } xy = c.$$

\Rightarrow the particles in the planar flow associated with $f(z) = \bar{z}$ move along curves in the family of hyperbolas $xy = c$.

$$\begin{aligned} x &= c_1 e^t \\ y &= c_2 e^{-t} \quad \text{where } c_1 c_2 = c \\ \Rightarrow xy &= c \quad \text{where } c_1 c_2 = c \\ \text{if } c &\text{ is positive then either } c_1 > 0 \text{ or } c_1 < 0 \\ y &= \frac{c}{x} \\ \text{When } t &\text{ increases, } x \text{ increases, } y \text{ decreases} \end{aligned}$$

Figure : Fig.1

Now, in order to plot the curve, $z(t) = x(t) + iy(t)$, we eliminate t in the equation 2, okay, you can see here we have $x = c_1 e^t$, $y = c_2 e^{-t}$, so from here you can see when you multiply x and y , $xy = c_1 c_2$, $c_1 c_2$ we can write as a new constant c , so eliminating t , we get $xy = c$ and therefore, $xy = c$ for different values of c , give us rectangular hyperbolas, so the particles in the planar flow associated with $f(z) = \bar{z}$ conjugate move along curves in the family of hyperbolas $xy = c$, you can see here $xy = c$; if your c is constant, then you get the hyperbola in the first and third quadrant.

If your c is negative, you get the hyperbolas in the second and fourth quadrant okay, now you can also see how mention the directions of the flow here, you can see that from here, $x = c_1 e^t$, $y = c_2 e^{-t}$, okay so let us see here, $x = c_1 e^t$, $y = c_2 e^{-t}$, okay so that $xy = c$, okay where $c = c_1 c_2 = c$, so e^t is always positive, we know, e^{-t} is always positive, okay.

So, if c_1 and $c_2 > 0$; if c is positive either c_1 and c_2 both are positive or c_1 and c_2 both are negative okay, so what will happen; if c_1 is positive, c_2 is positive, okay, you can see here, okay if $xy = c$, so when x is positive, it means c_1 is positive, so $y = c/x$, so when your x increases, you see $y = \text{some constant divided by } x$, so when x goes to; when x increases okay, x increases y decreases.

So, $x = c_1 e^{ct}$ and $y = c_2 e^{-ct}$ goes, t increases, x increases, okay and here what happens you see when x increases, when t increases, x increases because of $c_1 e^{ct}$ to the power t , x increases and when t increases, y decreases, okay because $y = c_2 e^{-ct}$ to the power $-t$, so when t increases, e^{-ct} decreases, so what happens when time increases okay, the fluid flow is in this direction like this, okay.

You see when t increases, y decreases, so the value of y decreases and the value of x increases also, the fluid flow is in this direction, okay similarly here in this quadrant, what happens when c_1 and c_2 both are negative, so here what will happen x will be a negative of e^{ct} to the power t , so when t will increase, okay, x will be negative, here y ; when c_2 is negative, y will also be negative, x and y are negative.

So, when t increases, okay what will happen, x will go towards; x will go to $-\infty$, when t will go to 0 , when t will go to $-\infty$, x will go to $-\infty$ and here when x ; t will go to $-\infty$, t will go on increase and then this will go to 0 , so y will go to 0 and therefore, the fluid flow is in this direction, so the fluid, directions of the fluid flow are determined by the set that as t increases, what happens to the values of x and y .

So, the values of x and y as t increases, I mean determine the direction of the fluid flow, so this is how we decide the directions of the fluid flow, the particles of the fluid flow move along the family of hyperbolas $xy = c$ here.

(Refer Slide Time: 09:48)

Example 2

Let $f(z) = \bar{z}^2 = (x - iy)^2$ then

$$P(x, y) = x^2 - y^2, Q(x, y) = -2xy$$

Hence,

$$\frac{dx}{dt} = x^2 - y^2, \frac{dy}{dt} = -2xy$$

or

$$\frac{v + x \frac{dv}{dx}}{dx} = \frac{-2v^2 x^2}{x^2(1-v^2)}$$

$$\frac{x \frac{dv}{dx}}{dx} = \frac{-2v^2 - v^4}{1-v^2}$$

Hence,

$$\frac{1-v^2}{v^3-3v} dv = \frac{dx}{x}$$

$$\frac{dy}{dx} = -\frac{2xy}{x^2 - y^2}$$

$$x^2 y - \frac{1}{3} y^3 = c'$$

$$\begin{aligned} f(z) &= (x - iy)^2 \\ &= (x^2 - y^2) - 2ixy \\ &= P(x, y) + iQ(x, y) \end{aligned}$$

$$P(x, y) = x^2 - y^2$$

$$Q(x, y) = -2xy$$

$$\frac{dx}{dt} = P(x, y) = x^2 - y^2$$

$$\frac{dy}{dt} = Q(x, y) = -2xy$$

$$\frac{dy}{dx} = \left(\frac{dy/dt}{dx/dt} \right) = \frac{-2xy}{x^2 - y^2}$$

Let us put $y = vx$
so that $v + x \frac{dv}{dx} = \frac{dy}{dx}$

Now, let us take another function $fz = z$ conjugate square which is $x - iy$, z conjugate is $x - iy$, so $x - iy$ square and when we square this, you get x square $- y$ square, $x - y$ the whole square gives you x square $+ I$ square y square, I square is -1 , so x square $- y$ square $- 2i xy$. Now, $fz = P xy + i Q xy$, so $P xy = x$ square $- y$ square and $Q xy = -2xy$, so this is how we get the values of $P xy$ and $Q xy$. Now, $dx/dt = P xy$, $dx/dt = P xy$, so we get $dx/dt = x$ square $- y$ square.

And $dy/dt = Q xy$, which gives us $-2xy$, okay, so what do we get; we get 2 equations; $dx/dt = x$ square $- y$ square, $dy/dt = -2xy$, so what we get; $dy/dx = dy/dt$ divided by dx/dt , okay, so this = $-2xy$ over x square $- y$ square, okay, now we have to solve this equation, so we can solve this equation, this is a homogenous equation, you can see homogenous equation, so let us put $y = v * x$, so that $v + x dv over dx = dy over dx$, okay.

And then $v + x dv over dx$, this equation okay, this equation, $dy/dx = - 2xy$ over x square $- y$ square gives us $v + x dv over dx = -2 vx$ square divided by x square times $1 - v$ square, okay. So, we can cancel out x square and then what we get; $x dv/dx = - 2v$ upon $1 - v$ square $- v$, okay, so what do you get; when you take the LCM, $1 - v$ square we have $- 2v$ and then we have $-v$, then we have $+ v$ cube, so v cube $- 3v$ upon $1 - v$ square, now separating variables x and v , we have $1 - v$ square divided by v cube $- 3v dv = dx/x$, okay.

(Refer Slide Time: 13:37)

$$\begin{aligned}
 \frac{1-v^2}{v^3-3v} dv &= \frac{dx}{x} \\
 \frac{1-v^2}{v^3-3v} &= \frac{1-v^2}{v(v^2-3)} = \frac{1-v^2}{v(v-\sqrt{3})(v+\sqrt{3})} = \frac{A}{v} + \frac{B}{v-\sqrt{3}} + \frac{C}{v+\sqrt{3}} \quad v = \frac{y}{x} \\
 A &= \left(\frac{1-v^2}{v^2-3} \right)_{v=0} = -\frac{1}{3} \\
 B &= \left(\frac{1-v^2}{v(v+\sqrt{3})} \right)_{v=\sqrt{3}} = \frac{1-3}{\sqrt{3}(2\sqrt{3})} = \frac{-2}{2 \times 3} = -\frac{1}{3} \\
 C &= \left(\frac{1-v^2}{v(v-\sqrt{3})} \right)_{v=-\sqrt{3}} = \frac{1-3}{(-\sqrt{3})(-2\sqrt{3})} = \frac{-2}{2 \times 3} = -\frac{1}{3} \\
 \text{Then, } \int \frac{(1-v^2)dv}{v^3-3v} &= -\frac{1}{3} \left[\int \frac{1}{v} + \frac{1}{v-\sqrt{3}} + \frac{1}{v+\sqrt{3}} \right] dv = \int \frac{dx}{x} \\
 \Rightarrow -\frac{1}{3} [\ln v + \ln(v-\sqrt{3}) + \ln(v+\sqrt{3})] &= \ln x + \ln c \\
 -\frac{1}{3} \ln v(v^2-3) &= \ln x + \ln c \quad \Rightarrow v(v^2-3) = c' x^{-3} \\
 \ln v(v^2-3) &= -3 \ln x - 3 \ln c \quad \Rightarrow \frac{y}{x} (y^2-3x^2) = c' x^3 \\
 \Rightarrow y(y^2-3x^2) &= c' x^3
 \end{aligned}$$

Now, you can see we have $dx \frac{1-x^2}{x^3-3x}$ on v^3-3v , $dv = dx$ over x , okay, so we can bracket into partial fractions and then integrate, so let us take consider $1-v^2$ upon v^3-3v , I can write it as $1-v^2$ upon v times v^2-3 which is $1-v^2$ upon v times $v-\sqrt{3}$ and $v+\sqrt{3}$, then I can write it as A over v + B over $v-\sqrt{3}$ + C over $v+\sqrt{3}$, the values of A, B, C we can find.

$A = 1-v^2$ divided by; you remove v from here, remaining is v^2-3 and put $v=0$, so we get, this is 1 and this is -3, so $-1/3$, $B = 1-v^2$ divided by $1-v-\sqrt{3}$ here, so $v \cdot v + \sqrt{3}$ and then put $v = \sqrt{3}$, so we get $1-3$ divided by $\sqrt{3} \cdot 2\sqrt{3}$ and we get here -2 divided by $2 \cdot 3$, so what do we get, $-1/3$ here also and then C similarly is $1-v^2$ over $v \cdot v - \sqrt{3}$ and we put $v = -\sqrt{3}$.

So, what do we get, $1-3$ divided by $-\sqrt{3} \cdot 2\sqrt{3}$ and what we get here, -2 divided by; this is how much, $2 \cdot 3$, so you can see $-1/3$ here also, okay, so thus $1-v^2$ over v^3-3v , this is $-1/3$, A, B, C all are equal, so 1 upon v + 1 upon $v-\sqrt{3}$ + 1 upon $v+\sqrt{3}$, okay, so integral of this, okay, we integral here = integral of dx/x , so what we get; $-1/3$ and we get $\ln v + \ln v - \sqrt{3} + \ln v + \sqrt{3} = \ln x + \text{some constant}$ let us write $\ln c$, okay.

So, what we get here, $1/3$; $-1/3 \ln v + \ln A \ln B \ln C$ is $\ln ABC$, so we have $\ln v \cdot v - \sqrt{3} \cdot v + \sqrt{3}$, so v ; v^2-3 , okay = $\ln x + \ln c$ and you can multiply by -3 here and what do we

get here, so $\ln v * v^2 - 3 = -3 \ln x - 3 \ln c$, okay, so what we get here, this gives you, $v^2 - 3 = x^{-3}$, some constant $c^{-3} * x^{-3}$. Now, by $v = y/x$, so I can write here, $y^2/x^2 - 3 = c^{-3}/x^3$.

So, this gives you $y^2 - 3x^3 = c^{-3}$, okay, so you can see here, $x^{-1/3} y^2 = c^{-3}$, this same as that here you see y^2 or you can say $y^2 - 3x^3 = c^{-3}$, okay, so this solution is same as this solution here we have, $3x^3 - y^2 = c^{-3}$.

(Refer Slide Time: 19:00)

Taking $c' = \pm \frac{2}{3}, \pm \frac{16}{3}, \pm 18$, the stream lines are as shown in the figure:

Figure : Fig.2

Now, taking $c' = \pm 2/3$, in this equation here, let us take the particular values of c' , okay and then we have plot it here, so $c' = \pm 2/3, \pm 16/3, \pm 18$, these streamlines are as shown in the figure. So, these are the streamlines for the values of $c' = \pm 2/3, \pm 16/3, \pm 18$, the direction as we have said earlier, the directions are decided accordingly by taking a parameter.

(Refer Slide Time: 19:35)

If there exists a function ϕ , called velocity potential, such that

$$P(x, y) = \frac{\partial \phi}{\partial x} \text{ and } Q(x, y) = \frac{\partial \phi}{\partial y}$$

then

$$f(z) = \frac{\partial \phi}{\partial x} + i \frac{\partial \phi}{\partial y}$$

\Rightarrow the velocity vector is the gradient of the velocity potential

\Rightarrow the fluid flow is irrotational or circulation free.

$$\vec{V} = P(x, y)\hat{i} + Q(x, y)\hat{j}$$

$$f(z) = P(x, y) + iQ(x, y)$$

$$\vec{V} = \frac{\partial \phi}{\partial x}\hat{i} + \frac{\partial \phi}{\partial y}\hat{j}$$

$$= \nabla \phi$$

$$f(z) = \frac{\partial \phi}{\partial x} + i \frac{\partial \phi}{\partial y}$$

$$\text{where } \vec{V} = \nabla \phi$$

We know that

$$\text{curl grad } \phi = 0$$

$$\Rightarrow \text{curl } \vec{V} = 0$$

\Rightarrow the fluid flow is irrotational

Now, if there exists a function ϕ called velocity potential such that all $P_{xy} = \text{partial derivative of } \phi \text{ with respect to } x, P_{xy} = \phi_x, Q_{xy} = \phi_y$, then $f(z)$; $f(z)$ was $P_{xy} + iQ_{xy}$, so $f(z)$ will be $= \phi_x + i\phi_y$, the velocity vector is the gradient of the velocity potential; velocity potential because velocity vector was this, velocity vector was $P_{xy}\hat{i} + Q_{xy}\hat{j}$ which we have written in the complex form $P_{xy} + iQ_{xy}$, okay.

So, v is actually P_{xy} is ϕ_x , Q_{xy} ϕ_y , so velocity vector = this, which is nothing but $\text{grad } \phi$ in 2 dimensions, okay and the equivalent form of this is $f(z) = i\phi$ this okay, so this is the velocity vector is the gradient of the velocity potential, this means that the fluid flow is irrotational or circulation free because when the velocity vector is gradient when $v = \text{del } \phi$, we know that $\text{curl of grad } \phi = 0$, okay.

So, $\text{curl of } v$ velocity vector will be 0 and this implies that the fluid flow is irrotational or we call it circulation free.

(Refer Slide Time: 21:55)

If the fluid is incompressible i.e. the density is constant then the divergence of the velocity vector is zero hence

$$\frac{\partial}{\partial x} P(x, y) + \frac{\partial}{\partial y} Q(x, y) = 0$$

or

$$\frac{\partial^2 \phi}{\partial x^2} + \frac{\partial^2 \phi}{\partial y^2} = 0$$

$\Rightarrow \phi$ is a harmonic function.

$$\begin{aligned} \text{div } \vec{V} &= \nabla \cdot \vec{V} = 0 \\ &= \left(i \frac{\partial}{\partial x} + j \frac{\partial}{\partial y} \right) \cdot \left(P(x, y) i + Q(x, y) j \right) \\ &= \frac{\partial P(x, y)}{\partial x} + \frac{\partial Q(x, y)}{\partial y} \\ &= \frac{\partial^2 \phi}{\partial x^2} + \frac{\partial^2 \phi}{\partial y^2} = 0 \end{aligned}$$

Now, if the fluid is incompressible that means the density does not change the time, okay, the density is constant then the divergence of the velocity vector is 0 and hence $\frac{\partial}{\partial x} P + \frac{\partial}{\partial y} Q = 0$ because when the divergence of the velocity vector is $\nabla \cdot \vec{v}$, okay, $\nabla \cdot \vec{v}$ means, oh this we have written as this okay, so this is $\frac{\partial}{\partial x} P + \frac{\partial}{\partial y} Q = 0$.

So, if the fluid is incompressible that is the density is constant, then the divergence of velocity vector is 0 and hence we have $P = \phi_x$, so and $Q = \phi_y$, so we will get this, this is nothing but this, okay, which is $= 0$, divergence of $\vec{v} = 0$, okay, so this is $= 0$ and this implies that ϕ is a harmonic function.

(Refer Slide Time: 23:40)

Let ψ denote the conjugate harmonic function of ϕ then $\Omega(z) = \phi(x, y) + i\psi(x, y)$ is analytic. The function $\Omega(z)$, of fundamental importance in characterizing a flow, is called the complex velocity potential.

The one parameter family of curves

$$\psi(x, y) = c \Rightarrow \frac{dy}{dx} = -\frac{\psi_x}{\psi_y} = \frac{\phi_y}{\phi_x}, \quad (\text{by C-R equations})$$

$$\phi_x = \psi_y$$

$$\phi_y = -\psi_x$$

$$\vec{V} = P(x, y)\hat{i} + Q(x, y)\hat{j}$$

$$\Rightarrow \frac{dy}{dx} = \frac{Q(x, y)}{P(x, y)}$$

\Rightarrow the resultant velocity of a particle is along the tangent to the curve $\psi(x, y) = c$.
So the particle moves on the curve $\psi(x, y) = c$. These curves are called stream function.

Now, let us assume that ψ denote the conjugate harmonic function of ϕ then we can write the associated analytic functions, $\Omega(z)$; $\Omega(z) = \phi(x, y) + i\psi(x, y)$, this function $\Omega(z)$ is very important in characterising the flow, is called the complex velocity potential, the one parameter family of curves, $\psi(x, y) = \text{constant}$, consider the conjugate harmonic function and then the level; $\psi(x, y) = \text{constant}$, $\psi(x, y) = \text{constant}$ gives you $dy/dx = -\psi_x / \psi_y$.

But since the function $\Omega(z)$ is analytic, ϕ and ψ that is ϕ Cauchy- Riemann equations, so using Cauchy- Riemann equations, $\phi_x = \psi_y$ and $\phi_y = -\psi_x$, we can write $\psi_x = -\phi_y$ divided by $\psi_y = \phi_x$, so this $-\psi_x / \psi_y$ becomes ϕ_y / ϕ_x and therefore ϕ_y is $Q(x, y)$ and ϕ_x is $P(x, y)$, so $dy/dx = Q(x, y) / P(x, y)$ and therefore, the resultant velocity, okay the resultant velocity of a particle is along the tangent to the curve.

Because the velocity of the particle has the direction given by; see the velocity v is what; velocity vector is, so the direction of the velocity vector v is given by the slope, by the $Q(x, y) / P(x, y)$ and here what do we notice; $dy/dx = Q(x, y) / P(x, y)$, so the resultant velocity of a particle is this is the slope of the tangent to the curve $\psi(x, y) = c$, so resultant velocity of a particle is along the tangent to the curve, $\psi(x, y) = \text{constant}$.

So, the particle moves on the curve $\psi(x, y) = c$, these curves are called the stream lines, okay and the function $\psi(x, y)$ is called stream function.

(Refer Slide Time: 26:01)

The curves $\phi(x, y) = c'$ are called equipotential lines. They cut the stream lines orthogonally.

Note that

$$\Omega'(z) = \phi_x + i\psi_x = \phi_x - i\phi_y = \overline{f(z)}$$

$$\text{or } f(z) = \overline{\Omega'(z)}.$$

Flow around a corner

The complex potential

$$f(z) = z^2 = (x^2 - y^2) + 2ixy$$

describes a flow whose equipotential lines are the hyperbolas $\phi = x^2 - y^2 = c$ and whose stream lines are the hyperbolas $\psi = 2xy = c'$.

The velocity components at a point are

$$\vec{v} = P(x, y)\hat{i} + Q(x, y)\hat{j}$$

$$P(x, y) = \frac{\partial \phi}{\partial x} = 2x$$

$$Q(x, y) = \frac{\partial \phi}{\partial y} = -2y$$

Now the curve $\phi = c$, the level curves $\phi = c$ are called equipotential lines and we know that ϕ and ψ are double curves, $\phi = \text{constant}$ and $\psi = \text{constant}$, they cut each other at right angles, so the stream lines cut the equipotential lines orthogonally, okay, so note that now let us consider $\Omega(z)$, $\Omega(z) = \phi + i\psi$, we know that if fz is an analytic function and u and v are its real and imaginary parts.

If fz is an analytic function, and is real and imaginary parts and $fz = u + iv$, then $f(z) = u + iv$, $f(z) = ux + i vx$, this we already know okay, so here $\Omega(z)$ will be $\phi + i\psi$ okay but using again Cauchy- Riemann equations, $\psi_x = -\phi_y$, we get $\Omega(z) = \phi - i\phi_y$. Now, $fz =$; we have $fz = P + iQ$; P is ϕ_x Q is ϕ_y , so fz conjugate will be $\phi_x - i\phi_y$, okay, this implies fz conjugate = $\phi_x - i\phi_y$ okay.

So, this is a $\Omega(z) = f(z)$ conjugate or we can say $fz = \text{conjugate of } \Omega(z)$, now let us discuss the flow around a corner, the complex potential $fz = z^2$ let us consider the complex potential $fz = z^2$, when you put $z = x + iy$, z^2 gives $x^2 - y^2 + 2yix$, this describes a flow which equipotential lines are the; now equipotential lines are given by $\phi = \text{constant}$, let us compare this with this function, okay.

This fz is the complex potential function, ωz and this fz is same as this ωz , so $fz =$; here $fz = \omega z$, okay and ωz is $\phi xy + i \psi xy$ and so $\phi xy = x^2 - y^2$ and $\psi xy = 2xy$, okay. Now, so equipotential lines are given by $\phi xy = \text{constant}$, so $x^2 - y^2 = \text{constant}$ which are the hyperbolas, they are given us the equipotential lines and the streamlines are given by $\psi xy = \text{constant}$.

So that means, $2xy = c$ dash, so these give the stream lines and this give equipotential lines, the velocity components at a point are; now, velocity vector v okay, $= P xy i + Q xy j$, these are the velocity components, $P xy$ and $Q xy$ and we know that $P xy = \phi x$, $Q xy = \phi y$, so $P xy = \phi x$ and $P xy =$; $\phi x = 2x$, okay, so $P xy = 2x$ and $\phi y = -2y$, so $Q xy = -2y$, okay.

(Refer Slide Time: 30:43)

So the magnitude of the resultant velocity $= 2\sqrt{x^2 + y^2}$. ✓
The figure shows the flow in a channel bounded by the axes (stream lines $2xy = 0$) and a hyperbola $xy = a^2$. The continuous lines are the stream lines and the dotted ones, the equipotential lines.

$$\begin{aligned} P(xy) &= 2x \\ Q(xy) &= -2y \\ |\vec{v}| &= \sqrt{(P(xy))^2 + (Q(xy))^2} \\ &= \sqrt{(2x)^2 + (-2y)^2} \\ &= 2\sqrt{x^2 + y^2} \end{aligned}$$

Figure : Fig.3

equipotential lines
 $x^2 - y^2 = c$ ✓
Streamlines
 $2xy = c$
When $c = 0$
the streamlines
are the x and
 y axes

And so, magnitude of resultant velocity, now we know $P xy = \phi x$ which is $2x$, $Q xy = \phi y$ which is $-2y$, so magnitude of resultant velocity will be velocity vector, magnitude of resultant velocity vector will be $P xy^2 + Q xy^2$ which is $2x^2 + (-2y)^2$ under root, so this is 2 times under root $x^2 + y^2$, so the magnitude of the resultant velocity is 2 under root $x^2 + y^2$.

Now, you can see in this figure, we have a flow in a channel, okay bounded by the axes, this is; these axis is $y = 0$, this axis is $x = 0$ and we have seen equipotential lines are $x^2 - y^2 = \text{constant}$ and a streamlines are given by $2xy = \text{constant}$, okay, so when you take the constant c

So, the figure shows the flow in a channel bounded by the axes and axes are the streamline, so when $c = 0$, the streamlines are the x and y axis, okay, the continuous lines are the streamlines, these are streamlines, you can see, these are streamlines okay, given by the hyperbola, you can see here c you can take as because we are taking the $\pi/2$ quadrant, so you can take c to be positive, so $xy = a$ square.

(Refer Slide Time: 33:42)

Source and Sink

Consider the complex potential

where c is a positive real constant. Then

$C = 0$ means, $y = + - x$, so this is $y = x$ plane, consider the complex potential $\omega z = c$ over $2\pi \ln z$, let us consider this complex potential, $\omega z = c$ over $2\pi \ln z$, where c is the positive real constant then $\omega z = c$ over 2 , let us write the polar form of the; let me function z , we can write it as $\ln \text{mod of } z + i \text{ argument of } z$, so $\omega z = c$ over $2\pi \ln \text{mod of } z + \text{argument of } z$

and I can write that as $c \text{ over } 2\pi \ln r$ mod of $z =;$ z we are taking as $r e$ to the power $i \theta$ which implies that mod of $z = r$ and $\theta =;$

So, using polar form of the complex number z , we have $c \text{ over } 2\pi \ln r + i c \text{ over } 2\pi$ argument of z . now, $\omega z = \phi x y + i \psi x y$, okay, so $\omega z = \phi x y + i \psi x y$, so this gives you $\phi x y = c \text{ over } 2\pi \ln r$ and $\psi x y = c \text{ over } 2\pi r z$, okay.

(Refer Slide Time: 35:11)

then

$$\Omega'(z) = \frac{\partial \phi}{\partial x} - i \frac{\partial \phi}{\partial y} = \frac{c}{2\pi r^2} (x - iy) \quad \checkmark \quad \text{we have } \frac{c}{2\pi r^2} (x - iy) = -\Omega(z)$$

Hence complex representation of the velocity field is given by

$$f(z) = \frac{c}{2\pi r^2} (x + iy) \quad \checkmark \quad \begin{aligned} &= \frac{c}{2\pi r^2} (x + iy) \\ \vec{V} &= \frac{c}{2\pi r^2} (x\hat{i} + y\hat{j}) \\ &= \frac{c}{2\pi r^2} \vec{r} \end{aligned}$$

\Rightarrow the flow is directed radially outward \checkmark

Hence the given complex potential corresponds to a point source at $z = 0$ (i.e. a source line $x = 0, y = 0$ in space)

The constant c is called the strength or discharge of the source.

If $c < 0$, the flow is said to have a sink at $z = 0$, it is directed radially inward, a fluid disappears at the singular point $z = 0$ of the complex potential.

And then what we get is $\omega \text{ dash } z$, now $\omega \text{ dash } z$ we know is $\phi x - i \psi y$, okay and what is ϕx ; just find ϕx here, so ϕx let us find, this gives you $\phi x = c \text{ over } 2\pi$ partial derivative of $\ln r$, okay, so this is $c \text{ over } 2\pi$, partial derivative of $\ln r$ with respect to x is $1 \text{ over } r$ * partial derivative of r with respect to x . Now, this gives us $r^2 = x^2 + y^2$, so this gives you $2r, r_x = 2x, r, r_x = x/r$.

So, this is $c \text{ over } 2\pi x / r^2$ okay and similarly, we find the partial derivative of ψ with respect to x , so partial derivative of ψ with respect to x is $c \text{ over } 2\pi$, let us represent this $r z$, $r z$ is θ , okay, so $\Delta \theta / \Delta x$ okay, what do we know that we have $\theta = \tan^{-1} y / x$, so we differentiated partially with respect to x , so we get this one, okay and this gives you $-y \text{ over } x^2 + y^2$, okay, so this is $-y \text{ over } r^2$.

So, let us put the values then thus $\frac{\partial \psi}{\partial x} = \frac{c}{2\pi} \frac{y}{r^2}$, so this is the value of ψ_x and here is the value of ψ_y , let us put these values in the expression here okay, so I have put here $\psi_x - i\psi_y$, so you get the same thing when you find $\psi_x - i\psi_y$, so we get $\frac{c}{2\pi} \frac{x - iy}{r^2}$ okay and we know that fz okay, let us recall that $fz = \omega \bar{z}$ conjugate.

So, we have $\omega \bar{z}$ conjugate, and therefore, the conjugate of this is $\frac{c}{2\pi} \frac{x + iy}{r^2}$ okay, so you can see $fz =$ this complex form of the potential okay, so flow; the flow, you see if you write the v , the vector, you see v vector will be; v vector is will be $\frac{c}{2\pi} \frac{xi - yj}{r^2}$ okay, because this is the complex form of the velocity potential, okay, v velocity vector. So, v is; so this means that the velocity vector is along the direction of $xi + yj$ vector, okay that is the flow is directed readily also.

This r vector, this $\frac{2c}{2\pi} \frac{1}{r^2} * r$ vector in the direction of r vector, the flow is in the direction of r vector that means it is directed readily outward, hence the given complex potential corresponds to a point source at $z = 0$, that is a source line $x = 0, y = 0$ in a space, the constant c is called the strength this constant c is called the strength or the discharge of the source. If $c < 0$, then the direction of the fluid flow will be towards the source, okay.

Then the flow will be said to have a sink at $z = 0$ because the flow is directed readily inward, a fluid disappears at the in this case a fluid disappears at the similar point, $z = 0$ of the complex potential.

(Refer Slide Time: 40:09)

Figure : Fig.4

So, this is the figure, you can see the flow is; if there is a source here, the flows is directed readily outward, okay, so these are the; these are equipotential lines okay and these are streamlines, these are streamlines because flow of the fluid is along the streamlines and these are equipotential lines, this we can see here also, you can see we have $\phi(x,y) = \text{constant}$, when you take $\phi(x,y) = \text{constant}$, $\frac{c}{2\pi} \ln r$ is a constant, okay.

Ln, so $\ln r$ will be a constant and $\ln r$ is a constant when r is constant, okay, $\phi(x,y) = \text{constant}$ implies that r is constant and $\psi(x,y) = \text{constant}$ implies $\arg z = \text{constant}$ that is $\theta = \text{constant}$, okay, so $\phi(x,y) = \text{constant}$ means, $\frac{c}{2\pi} \ln r$ is a constant and which implies that r is a constant, okay r is constant means concentric circles, okay, so these are equipotential lines, okay and then similarly, $\psi(x,y) = \text{constant}$ means, $\frac{c}{2\pi} \arg z$ is a constant which means that $\arg z$ is a constant, okay, $\arg z$ is θ , so θ is a constant, okay.

So, for the radial lines, θ is constant and therefore, the fluid flows along the radial lines, radially outward.

(Refer Slide Time: 42:29)

Gravitational Field

Let a particle 'A' of mass M be fixed at a point P_0 and let a particle 'B' of mass m be free to take up various positions P in space. Then 'A' attracts 'B'. According to Newton's law of gravitational force \vec{p} is directed from P to P_0 and its magnitude is proportional to $\frac{1}{r^2}$, where r is the distance between P and P_0 , say,

$$|\vec{p}| = \frac{c}{r^2} = \frac{GMm}{r^2},$$

where $G = 6.67 \times 10^{-8} \text{ cm}^3/\text{gm}.\text{sec}^2$ is the gravitational constant. Hence, \vec{p} defines a vector field in space. Let P_0 and P be given by (x_0, y_0, z_0) and (x, y, z) respectively. Then $r = \sqrt{\sum (x - x_0)^2}$ and $\vec{r} = (x - x_0)\hat{i} + (y - y_0)\hat{j} + (z - z_0)\hat{k}$.

Now, let us consider another example that of a gravitational field, let a particle A of mass M be fixed at a point P_0 and let a particle B of mass m be free to take up various positions P in space, then we know that A attracts B and according to Newton's law of gravitational force, the gravitational force P is directed from P to P_0 , the magnitude of this force is proportional to 1 over r square, where r is the distance between P and P_0 .

And its given by; magnitude of P is given by c over r square where c is a constant and the constant is $G * M * m$; $G * \text{capital } M * \text{small } m$ divided by r square, where G is gravitational constant, G is given by $6.67 * 10$ to the power -8 centimetre cube divided by gram second square, this is the gravitational constant and the P vector defines a vector field in space. So, let P_0 has coordinates x_0, y_0, z_0 .

And the point P has coordinates x, y, z then the vector r will be given by $x - x_0 * \hat{i} + y - y_0 * \hat{j} + z - z_0 * \hat{k}$ and its magnitude r will be square root $x - x_0$ whole square + $y - y_0$ whole square + $z - z_0$ whole square which we have written as $\sigma \sum (x - x_0)^2$.

(Refer Slide Time: 43:56)

Then

$$\vec{p} = |\vec{p}| \left(-\frac{\vec{r}}{r} \right) = -\frac{c}{r^3} \vec{r}$$

$$\vec{p} = |\vec{p}| \frac{\vec{r}}{r}$$

This vector function describes the gravitational force on B. Let us note that $|\vec{p}| = \frac{c}{r^2}$

$$\frac{\partial}{\partial x} \left(\frac{1}{r} \right) = -\frac{x - x_0}{r^3}, \quad \frac{\partial}{\partial y} \left(\frac{1}{r} \right) = -\frac{y - y_0}{r^3} \quad \checkmark \quad \vec{p} = \frac{c}{r^2} \left(-\frac{\vec{r}}{r} \right) = -\frac{c}{r^3} \vec{r}$$

and $\frac{\partial}{\partial x} \left(\frac{1}{r} \right) = -\frac{1}{r^2} \frac{\partial r}{\partial x}$
 $= -\frac{1}{r^2} \frac{x - x_0}{r}$
 $= -\frac{(x - x_0)}{r^3}$

$$\frac{\partial}{\partial z} \left(\frac{1}{r} \right) = -\frac{z - z_0}{r^3} \quad \checkmark$$

we have
 $r^2 = (x - x_0)^2 + (y - y_0)^2 + (z - z_0)^2$
 $2r \frac{\partial r}{\partial x} = 2(x - x_0)$
 $\Rightarrow \frac{\partial r}{\partial x} = \frac{x - x_0}{r}$
 $\frac{\partial r}{\partial y} = \frac{y - y_0}{r}$
 $\frac{\partial r}{\partial z} = \frac{z - z_0}{r}$

Hence

$$\nabla \left(\frac{c}{r} \right) = c \nabla \left(\frac{1}{r} \right)$$

$$\vec{p} = \nabla \left(\frac{c}{r} \right) = -\frac{c}{r^3} \vec{r}$$

$$= c \left[\hat{i} \frac{\partial}{\partial x} \left(\frac{1}{r} \right) + \hat{j} \frac{\partial}{\partial y} \left(\frac{1}{r} \right) + \hat{k} \frac{\partial}{\partial z} \left(\frac{1}{r} \right) \right] = -\frac{c}{r^3} \left[\hat{i} (x - x_0) + \hat{j} (y - y_0) + \hat{k} (z - z_0) \right] = -\frac{c}{r^3} \vec{r}$$

And the vector P then can be written as $P = \text{mod of } P \cdot \text{a unit vector in the direction of vector } P$, okay, these P0 and here is P okay, P vector is in this direction that is opposite to the direction of r, okay, so we divide r by its magnitude to get a unit vector in the direction of r and then we put a negative sign, we get $P = \text{mod of } P - r \text{ over } r$ and we know that mod of P = c over r square, okay, c over r square, so what do we get?

P vector = c over r square * - r vector divided by r okay, - c over r cube, okay, now we know that we have $r^2 = x - x_0 \text{ whole square, } y - y_0 \text{ whole square, } z - z_0 \text{ whole square}$, the distance between P0 and P, okay, so when you differentiate this with respect to x, what you get; you get this which implies $r_x = x - x_0 \text{ over } r$, similarly r_y if you find yz, vz; $y - y_0 \text{ over } r$ and $r_z = z - z_0 \text{ over } r$ we get, okay.

Now, partial derivative of 1 over r is -1 over r square * r_x , so that is = -1/ r square $x - x_0 \text{ over } r$, so we get $-x - x_0 \text{ over } r \text{ cube}$, similarly, the partial derivative of 1 over r with respect to y is $y - y_0$, $-y - y_0 \text{ over } r \text{ cube}$ and partial derivative of 1 over r with respect to z is $-z - z_0 \text{ over } r \text{ cube}$, okay, so what we get here, this vector P is nothing but del of c over r, why it is d over del of c over r, we will let us see that.

Del of c over r means c times del over del of 1 over r and del of 1 over r is what; c times i, okay this is what we have and this is how much; c times i del over del x 1 over r, del over del x 1 over

r is $-x - x_0$ over r cube, okay, so -1 over r cube we can write here, okay $-c$ over r cube we can write here then this is $x - x_0 + j, y - y_0 + k z - z_0$ which is r vector, so this is $-c$ over r cube r vector, okay.

So, $\text{del } c \text{ over } r$ okay, P ; if you write $P = \text{del } c \text{ over } r$, what you get is $-cr$ over r , so this $-c$ over r cube can be written as $\text{del of } c \text{ over } r$ and this means that the gravitational force P can be written as the gradient of a scalar potential which is c over r , okay.

(Refer Slide Time: 48:32)

The scalar function $f(x, y, z) = \frac{c}{r}$ is a potential of that gravitational field. Further,

$$\frac{\partial^2}{\partial x^2} \left(\frac{1}{r} \right) = -\frac{1}{r^3} + \frac{3(x-x_0)^2}{r^5} \quad \checkmark \quad \vec{\nabla} = \nabla f(-x, -y, -z) = \nabla \left(\frac{c}{r} \right)$$

$$\frac{\partial^2}{\partial y^2} \left(\frac{1}{r} \right) = -\frac{1}{r^3} + \frac{3(y-y_0)^2}{r^5} \quad \checkmark \quad \nabla^2 \left(\frac{c}{r} \right) = c \nabla^2 \left(\frac{1}{r} \right)$$

and

$$\frac{\partial^2}{\partial z^2} \left(\frac{1}{r} \right) = -\frac{1}{r^3} + \frac{3(z-z_0)^2}{r^5} \quad \checkmark \quad = 0$$

hence

$$\nabla^2 \left(\frac{1}{r} \right) = -\frac{3}{r^3} + \frac{3r^2}{r^5} = 0 \quad \checkmark \quad \Rightarrow \nabla^2 f(x, y, z) = 0$$

\Rightarrow The potential $f(x, y, z) = \frac{c}{r}$ satisfies the Laplace equation.

Handwritten notes on the right side of the slide:
 $\Rightarrow \nabla^2 f(x, y, z) = 0$
 $\frac{\partial^2}{\partial x^2} f(x, y, z) + \frac{\partial^2}{\partial y^2} f(x, y, z) + \frac{\partial^2}{\partial z^2} f(x, y, z) = 0$
 $\Rightarrow f(x, y, z) = \frac{c}{r}$
 $= \frac{c}{\sqrt{(x-x_0)^2 + (y-y_0)^2 + (z-z_0)^2}}$

So, the scalar function $f(x, y, z)$, let us write $P = \text{del of } f(x, y, z)$, there $f(x, y, z)$ is c over r , okay, so this $f(x, y, z)$, the scalar function $f(x, y, z) = c$ over r is a potential of that gravitational field, further if you differentiate 1 over r , we have differentiated 1 over r with respect to x and got this okay, $\text{del over } \text{del } x$ of 1 over $r =$ this, if you differentiate it further, you get $\text{del square over } \text{del } x$ square of $1/r$, if you differentiated it further with respect to x , we get $\text{del square/ } \text{del } x$ square of 1 over r .

And that comes out to be this, okay, similarly $\text{del square over } \text{del } y$ square upon over r comes out to be this and $\text{del square over } \text{del } z$ square upon r comes out to be this and when you adapt all of them, you get $\text{del square of } 1$ over r which is -3 over r cube $+ 3$ r square over r to the power 5 which is $= 0$ and therefore, $f(x, y, z) = c$ over r okay, $\text{del square of } c$ over $r = c$ times $\text{del square of } 1/r$, okay.

And this del square upon by r is 0, so this is 0, so del square of $f(x, y, z) = 0$, so this $f(x, y, z)$ satisfies the Laplace equation and therefore, this gravitational; this function, scalar function is called the gravitational potential.

(Refer Slide Time: 50:15)

Remark

In the two dimensional case, the potential function $f(x, y)$ is a harmonic function.

Steady state heat conduction

The heat flux across a surface is given by:

$$Q = -K \nabla T,$$

$$\nabla T = \frac{\partial T}{\partial x} \hat{i} + \frac{\partial T}{\partial y} \hat{j}$$

where T is the temperature and K is the thermal conductivity. In the two dimensional case

$$Q = -K \left(\frac{\partial T}{\partial x} + i \frac{\partial T}{\partial y} \right) = Q_x + i Q_y$$

Complex form of ∇T

⇒

$$Q_x = -K \frac{\partial T}{\partial x}, \quad Q_y = -K \frac{\partial T}{\partial y}$$

Now, in the 2 dimensional case, the potential function $f(x, y)$ okay is a harmonic function, here you can see we have taken in 3 dimensions, when you can see the 2 dimensional case, okay then you get $f(x, y) = c$ over r which satisfy the Laplace equation this one, in the 2 dimensional case, we have this and then we say that $f(x, y) = c$ over r okay that is c over under root r is what; $x - x_0$ whole square + $y - y_0$ whole square.

This is a harmonic function, okay, the heat flux across a surface, okay let us consider a steady state heat conduction, the heat flux across a surface is given by $Q = -K \text{ grad } T$, okay, where T is the temperature and K is the thermal conductivity, in the 2 dimensional case, $Q = -K$, now in the 2 dimensional case, the ∇T ; ∇T will be $\frac{\partial T}{\partial x} \hat{i} + \frac{\partial T}{\partial y} \hat{j}$, when you write the complex form of this, okay in the complex form ∇T can be written as $\frac{\partial T}{\partial x} + i \frac{\partial T}{\partial y}$, this is i , okay $\frac{\partial T}{\partial y}$.

This is the complex form of ∇T , okay, complex form of ∇T and so this is Q in the complex form is $Q_x + i Q_y$ and so $Q_x = -K \frac{\partial T}{\partial x}$, $Q_y = -K \frac{\partial T}{\partial y}$.

(Refer Slide Time: 52:27)

It follows that for a simple closed curve C in the z plane representing the cross section of a cylinder and for the steady state conditions (no net accumulation of heat inside C) we have

$$\frac{\partial Q_x}{\partial x} + \frac{\partial Q_y}{\partial y} = 0 \Rightarrow \frac{\partial^2 T}{\partial x^2} + \frac{\partial^2 T}{\partial y^2} = 0$$

$\Rightarrow T$ is a harmonic function. ✓

If U is the conjugate harmonic function, the function

$$\underline{W(z)} = T(x, y) + iU(x, y) \quad \checkmark$$

is an analytic function.

The families of curves $T(x, y) = \alpha$, $U(x, y) = \beta$ are called, respectively, isothermal lines and flux lines. $W(z)$ is called the complex temperature.

$$\begin{aligned} Q_x &= -k \frac{\partial T}{\partial x} \\ Q_y &= -k \frac{\partial T}{\partial y} \\ \frac{\partial Q_x}{\partial x} &= -k \frac{\partial^2 T}{\partial x^2} \\ \frac{\partial Q_y}{\partial y} &= -k \frac{\partial^2 T}{\partial y^2} \\ \text{Hence } \frac{\partial Q_x}{\partial x} + \frac{\partial Q_y}{\partial y} &= -k \left(\frac{\partial^2 T}{\partial x^2} + \frac{\partial^2 T}{\partial y^2} \right) \\ &= 0 \end{aligned}$$

Now, it follows that for a simple closed curve C in the z plane, okay representing the cross section of a cylinder and for the steady state conditions, okay that means no net accumulation of heat inside C we have, Q_x ; derivative of Q_x with respect to x + derivative of Q_y with respect to $y = 0$. Now, $Q_x = -K \frac{\partial T}{\partial x}$, $Q_y = -\frac{\partial T}{\partial y}$, so that gives you, okay, so $\frac{\partial Q}{\partial y}$, some $\frac{\partial y}{\partial y}$ gives you this, okay.

Hence, this is $= 0$, which means that $\frac{\partial^2 T}{\partial x^2} + \frac{\partial^2 T}{\partial y^2} = 0$ and this means that T is the harmonic function. Now, if you use the conjugate harmonic function of T , then the function $Wz = T + iU$ is an analytic function and the families of curves $T = \alpha$, $U = \beta$ are then respectively called isothermal lines, okay because along those lines, so $T = \alpha$, temperature remains constant.

So, they are called isothermal lines and $U = \beta$ are called the flux lines, Wz ; Wz is called the; this Wz is called the complex temperature. With this, I would like to end my lecture, thank you very much for your attention.
