Lecture – 53
Joint Probability Distribution - II

Hello friends welcome to my second lecture on joint probability distribution. Let us first consider the discrete case of 2 random variables. So in the case of discrete random variable xy with probability function f_{xy} , the probability that x takes the value x and y is arbitrary is given by f_1x = probability that x takes the value x , y is arbitrary.

(Refer Slide Time: 00:54)

Marginal distributions of a discrete two dimensional distribution

In the case of a discrete random variable (X, Y) with probability function $f(x, y)$, the probability $P(X = x, Y \text{ arbitrary})$ that X assumes the value x while Y assumes any value is given by

$$f_1(x) = P(X = x, Y \text{ arbitrary}) = \sum_y f(x, y).$$

This distribution is called the marginal distribution or marginal density of X with respect to the given two dimensional distribution. It has the cumulative distribution function

$$F_1(x) = P(X \leq x, Y \text{ arbitrary}) = \sum_{x^* \leq x} f_1(x^*).$$

So we take the sum of the function f_{xy} over all the values that the random variable y takes, this will give you the marginal distribution or marginal density of X with respect to the given 2 dimensional distribution. Now in the case of cumulative distribution function we have F_1x = probability that $X \leq x$ and Y arbitrary which will be $\sum f_1 x^*$, where x^* is $\leq x$.

So we will take the sum of the marginal density function over all values of x^* which are $\leq x$ to get the cumulative distribution function of x with respect to the given 2 dimensional distribution.

(Refer Slide Time: 01:45)

Marginal distributions of a discrete two dimensional distribution cont...

Similarly, the probability function

$$f_2(y) = P(X \text{ arbitrary}, Y = y) = \sum_x f(x, y).$$

is called the marginal density or marginal distribution of Y with respect to the given two dimensional distribution. The cumulative distribution function of this distribution is

$$F_2(y) = P(X \text{ arbitrary}, Y \leq y) = \sum_{y^* \leq y} f_2(y^*).$$

Both marginal distributions of a discrete random variable (X, Y) are discrete.

In the case of the marginal density function of Y with respect to the given 2 dimensional distribution we have F_2y = probability that X is arbitrary, $Y = y$ okay. This is defined in a similar manner as the case of marginal density function or marginal distribution of x with respect to the joint distribution xy . So probability that x is arbitrary, Y is $= y$ is σ , f_{xy} where x σ is taken over the values of x .

The value that x takes okay, so this is called the marginal density or marginal distribution of y with respect to the 2 dimensional distribution. The cumulative distribution function of this distribution that is cumulative distribution function of y with respect to the given 2 dimensional distribution is F_2y = probability that x is arbitrary, Y is $\leq y$, here we take the sum of the marginal density function over all values of y star that are $\leq y$.

Both the marginal distributions you can see of the discrete random variable XY are discrete.

(Refer Slide Time: 02:58)

Marginal distributions of a continuous two dimensional distribution

In the case of a continuous random variable (X, Y) with density function $f(x, y)$, we may consider $(X \leq x, Y \text{ arbitrary})$ or $(X \leq x, -\infty < Y < \infty)$, the corresponding probability is

$$F_1(x) = P(X \leq x, -\infty < Y < \infty) = \int_{-\infty}^x \left(\int_{-\infty}^{\infty} f(x^*, y) dy \right) dx^*.$$

Setting $f_1(x) = \int_{-\infty}^{\infty} f(x, y) dy$, we may write

$$F_1(x) = \int_{-\infty}^x f_1(x^*) dx^*,$$

where $f_1(x)$ is called the marginal density and $F_1(x)$, the cumulative distribution function of the marginal distribution of X with respect to the given continuous distribution.

Now in the case of a continuous random variable XY , with density function F_{xy} , we may consider $x \leq x, Y \text{ arbitrary}$ or $X \leq x - \infty < Y < \infty$. The corresponding probability function okay is given by $F_1x =$ the corresponding probability will be $F_1x = P X \leq x - \infty < Y < \infty$ this is integral over $-\infty$ to x , integral over $-\infty$ to ∞ $f_{x^*} y dy dx^*$.

This is the cumulative distribution function in the case of the cumulative distribution function of x with respect to the joint distribution xy . Here this integral over $-\infty$ to ∞ $f_{xy} dy$ is F_1x which is the marginal density function of x with respect to the joint distribution okay. So using this marginal density function F_1x we can write the cumulative distribution function F_1x as integral over $-\infty$ to x $F_1x^* dx^*$.

Where f_1x is called the marginal density and capital F_1x is called the cumulative distribution function of the marginal distribution of x . So this f_1x is called the marginal density or marginal distribution and F_1x the cumulative distribution function of the marginal distribution of x with respect to the given continuous distribution.

(Refer Slide Time: 04:34)

Marginal distributions of a continuous two dimensional distribution cont...

The function $f_2(y) = \int_{-\infty}^{\infty} f(x, y) dx$ is called the marginal density and

$$F_2(y) = \int_{-\infty}^y f_2(y^*) dy^* = \int_{-\infty}^y \int_{-\infty}^{\infty} f(x, y^*) dx dy^*$$

is called the cumulative distribution function of the marginal distribution of Y with respect to the given two dimensional distribution. We see that both marginal distribution of a continuous distribution are continuous.

0

Now in a similar manner we can define the marginal density function or marginal distribution of y with respect to the joint continuous distribution xy and the corresponding cumulative distribution function. So the marginal density function of y with respect to the joint distribution will be given by $f_2(y) = \int_{-\infty}^{\infty} f_{xy}(x, y) dx$ it is called the marginal density okay.

And the corresponding cumulative distribution function is $F_2(y) = \int_{-\infty}^y f_2(y^*) dy^*$ which is = integral over – infinity to y putting the value of $f_2(y^*)$ here, we get integral over – infinity to infinity $\int_{-\infty}^{\infty} f_{xy}(x, y^*) dx$, dy^* okay. So this is called the cumulative distribution function of the marginal distribution of y with respect to the given 2 dimensional distribution and both you can see the marginal distributions, that is $f_1(x)$, this $f_1(x)$ okay, this one and the next one $F_2(y)$ okay. They are continuous you can see.

(Refer Slide Time: 05:49)

Example 1

The following table gives the probability distribution of X and Y

Y/X	x=1	x=2	x=3	$f_{Y(y)}$
y=1	0.1	0.1	0.2	0.4
y=2	0.2	0.3	0.1	0.6
$f_{X(x)}$	0.3	0.4	0.3	

$X = 1, 2, 3$
 $Y = 1, 2$

Find (a) marginal density function of X, $\rightarrow f_X(x) = \sum_{y=1}^2 f(x,y), x=1,2,3$
(b) marginal density function of Y.

(a) $f_X(x) = \sum_{y=1}^2 f(x,y), x=1,2,3$

X	1	2	3
$f_X(x)$	0.3	0.4	0.3

(b) $f_Y(y) = \sum_{x=1}^3 f(x,y), y=1,2$

Y	1	2
$f_Y(y)$	0.4	0.6

Okay, let us consider the following example. The following table gives the probability distribution of X and Y okay. So this is Y, Y means these values are of Y, $Y = 1$, this is $Y = 2$ and here we have $X = 1$, $X = 2$, $X = 3$ okay, so we want to find the marginal density function of X first of all okay. Marginal density function of X means we want to determine f_{XX} okay. Marginal density function or marginal distribution of x okay.

So here you can see X takes the values 1, 2, 3 okay, Y takes the value 1, 2 okay. So f_{XX} we have to determine, f_{XX} will be given by $\sum_{y=1}^2 f_{XY}$ okay, yeah, so this will be f_X and f_{YY} , this is marginal density function of y. So f_{YY} will be $= \sum_{x=1}^3 f_{XY}$, x varies from 1 to 3 okay. Because x takes the values 1, 2, 3. Now you can see here when, so this is f_{XX} will be found for $x = 1, 2, 3$.

Okay and f_{YY} will be found for $y = 1, 2$ okay now you can see here. If you sum the column entries, okay, if you sum the column entries then you get the value of f_{XX} for $x = 1$ okay. So here you write this is f_{XX} okay. You can see here in this table. So f_{XX} , when $x = 1$, f_{XX} will be summation over all the values of y. $Y = 1$ to 2, so this is $0.1 + 0.2$ that is 0.3 okay. When $x = 2$, okay the values of y for 1 and 2 are 0.1 and 0.3.

So let us sum over the values of Y, so it is 0.4 okay and then when $x = 3$, the values of f_{XY} are for $y = 1$ it is 0.2, for $y = 2$ it is 0.1, so we have 0.3 okay. So we can say the marginal density function of x. The part a okay, so we have values of x here and we have f_{XX} here. Values of x are 1, 2, 3 and the values of f_{XX} are 0.3, 0.4, 0.3 okay, so this is the answer for the part a. This is marginal density function of x.

Now part b, so now we want to find marginal density function of y with respect to the joint distribution, so we have this. So this is our y, as y is taking values 1 and 2 okay, we want f_{yy} okay. So now what will happen f_{yy} is summing of the values of f_{xy} for x = 1 to 3, x goes from 1 to 3. So we now take the sum of entries in the rows okay. So we have this. So this is f_{yy}. Okay when y = 1 okay, you can sum the entries 0.1, 0.1, 0.2.

So 0.1, 0.1, 0.2 is 0.4 okay, summing of the values of f_{xy} okay when x runs from 1 to 3 means you take the sum of the entries in the row for y = 1 and then for y = 2 you take again the sum 0.2, 0.3, 0.1, so 0.6. So we have 0.4 and this is 0.6, so this is probability density function of, marginal density function of y and this is marginal density function of x.

(Refer Slide Time: 10:31)

Example 2
The joint density function of two continuous random variable X and Y is

$$f(x, y) = Cxy, 0 < x < 4, 1 < y < 5 ; \text{ and } 0, \text{ otherwise.}$$

(a) Find the value of constant C. ✓
(b) Find $P(X \geq 3, Y \leq 2)$.
(c) Find the marginal distribution function X.

Handwritten solution:

We know that $\int_{-\infty}^{\infty} \int_{-\infty}^{\infty} f(x, y) dx dy = 1 \Rightarrow \int_0^4 \int_1^5 Cxy dx dy = 1$

$\Rightarrow C \left(\frac{x^2}{2} \right)_0^4 \left(\frac{y^2}{2} \right)_1^5 = 1 \Rightarrow C \times 8 \times 12 = 1$
 $\Rightarrow C = \frac{1}{96}$

Handwritten calculation for (b):

$$P(X \geq 3, Y \leq 2) = \int_3^4 \int_1^2 f(x, y) dy dx = \int_3^4 \int_1^2 Cxy dy dx = \int_3^4 Cx \left(\frac{y^2}{2} \right)_1^2 dx = \int_3^4 Cx \left(\frac{4}{2} - \frac{1}{2} \right) dx = \int_3^4 Cx \left(\frac{3}{2} \right) dx = \frac{3C}{2} \left(\frac{x^2}{2} \right)_3^4 = \frac{3C}{4} (16 - 9) = \frac{3C}{4} \times 7 = \frac{3 \times \frac{1}{96} \times 7}{4} = \frac{7}{128}$$

NPTEL ONLINE CERTIFICATION COURSE

Let us now consider we have considered just now a discrete case of 2 discrete random variables, let us consider now a continuous case, continuous joint distribution of 2 continuous random variables. So the joint density function of 2 continuous random variables X and Y is given by f_{xy} = Cxy, x varies from 0 to 4 okay, y varies from 1 to 5, then f_{xy} Cxy and 0 otherwise okay.

So we have to determine the value of the constant C first. Okay we know that f_{xy} is the joint density function, so integral over – infinity to infinity, integral over – infinity to infinity f_{xy} dx dy will be = 1 okay. This implies that by the definition of f_{xy} integral 0 to 4, integral 1 to 5 or cxy dx dy = 1, because f_{xy} is 0 elsewhere okay. Now c is a constant, we integrate with respect to x to get x square/2 and it is 0 to 4 and then we have integrated.

When we integrate y , we get $y^2/2$ integral over 1 to 5 okay, this is $= 1$ okay. So this implies C times $16/2$ means 8 okay and then we have $25/2 - 1/2$, so $24/2$ that means 12, so we have $C = 1/96$ okay, so this is the value of the constant C . Now let us find the probability that x is ≥ 3 , y is ≤ 2 okay. So probability that x is ≥ 3 and y is ≤ 2 , will be given by integral over 3 to infinity okay.

x varies from 3 to infinity, y varies from $-\infty$ to 2, $f_{xy} dx dy$ okay. So by the definition of f_{xy} , it is only cxy over the interval 0 to 4 for x and 1 to 5 for y elsewhere it is 0. So this integral will become the integral from 3 to 4 for x , because when $x > 4$ it is 0, and for y it will be replaced by 1 to 2, because if it is x , $y < 1$, it is 0 okay. So $cxy dx dy$ okay. So let us now calculate it 3 to 4, 1 to 2.

(Refer Slide Time: 13:32)

$$\begin{aligned}
 \text{we have } P(X \geq 3, Y \leq 2) &= \int_3^4 \int_1^2 \frac{1}{96} xy \, dx \, dy \\
 &= \frac{1}{96} \left(\frac{x^2}{2} \right)_3^4 \left(\frac{y^2}{2} \right)_1^2 = \frac{1}{96} \left(8 - \frac{9}{2} \right) \left(2 - \frac{1}{2} \right) \\
 &= \frac{1}{96} \times \frac{7}{2} \times \frac{3}{2} = \frac{7}{128} \\
 \text{Marginal density function of } X & \\
 \Rightarrow f_X(x) &= \int_{-\infty}^{\infty} f(x, y) \, dy \\
 &= \int_1^5 cxy \, dy = \frac{1}{96} x \left(\frac{y^2}{2} \right)_1^5 = \frac{x}{96} \times \frac{25}{2} - \frac{x}{96} \times \frac{1}{2} = \frac{x}{8}, 0 < x < 4 \\
 \text{Thus } f_X(x) &= \begin{cases} \frac{x}{8}, & 0 < x < 4 \\ 0, & \text{elsewhere} \end{cases}
 \end{aligned}$$

So we have $P(X \geq 3, Y \leq 2)$ is given by this integral okay. So we integrate $1/96 * x \text{ square}/2$ integral over the limits are 3 to 4, then we have $y^2/2$ limits are 1 to 2. So this gives you $1/96$ and we have here $16/2$ means $8 - 9/2$ and we have here $4/2$ means $2 - 1/2$ okay. So this is $= 1/96$ and then we have $16 - 9$ so $7/2$ and we have here $3/2$ okay. So 3 when cancels with this we get 3 times 3 are 9 and 3 2s are 6.

So this is $7/128$ okay, so this is the probability when x is ≥ 3 , y is ≤ 2 . Now find the marginal distribution function of x . So we have to find the marginal density function of x okay. Now marginal density function of x is given by $f_X(x)$ and this is given by integral

over – infinity to x okay, $f_x y$, it is given by integral over – infinity to infinity $f_{xx} = \text{integral over – infinity to infinity } f_{xy} dy$ okay.

Yeah we have to because f_{xx} is probability that x takes the value x and y is arbitrary. So this is integral over y varies from 1 to 5 okay, elsewhere it is 0 for y , f_{xy} 0, so 1 to 5 okay and we have $\int_1^5 xy dy$ okay. So this c is $1/96 * x * y^2/2$ and we have limits 1 to 5 okay. So $x/96$ and we have $25/2$ when we put y as 5, $25/2 - 1/2$ so we have 12 okay. So 12 8s are 96, so we have $x/8$ okay.

So if x lies in the interval 0 to 4 okay, if x lies in the interval 0 to 4 then f_{xx} is $x/8$ okay. So thus $f_x x = x/8$ when $0 < x < 4$ and 0 elsewhere, because if your x does not lie in the interval 0 to 4 okay f_{xy} will be 0 okay. So this is for $0 < x < 4$, so this is the marginal density function of x okay for example 2.

(Refer Slide Time: 17:06)

Independence and dependence of random variable

The random variables X and Y of two-dimensional (X, Y) distribution with distribution function $F(x, y)$ are said to be independent if

$$F(x, y) = F_1(x)F_2(y)$$

holds for all (x, y) , otherwise these variables are said to be dependent. Suppose that X and Y are either both discrete or both continuous. Then X and Y are independent if and only if the corresponding probability functions or densities $f_1(x)$ and $f_2(y)$ satisfy

$$f(x, y) = f_1(x)f_2(y)$$

for all (x, y) .

 IIT ROORKEE
NPTEL ONLINE
CERTIFICATION COURSE

8

Now let us discuss independence, dependence of random variable. The random variables X and Y of 2-dimensional distribution $X Y$ with distribution function F_{xy} , cumulative distribution function F_{xy} are called independent okay if $F_{xy} = F_{1x} * F_{2y}$, it holds for all xy , otherwise these variables are said to be dependent. Suppose that x and y are both discrete okay, are both continuous then x and y are independent if and only if the corresponding probability functions are densities f_{1x} and f_{2y} satisfy $f_{xy} = f_{1x} * f_{2y}$ for all xy .

(Refer Slide Time: 17:49)

Independence and dependence of random variable cont...

For example the variables X =number of heads on a dime, Y =number of heads on a nickel in tossing a dime and a nickel once, may assume the values 0 and 1 and are independent.

The notion of independence and dependence may be extended to the n random variables of an n -dimensional (X_1, X_2, \dots, X_n) -distribution.

For example, you consider the case of random variables X and Y where X denotes the number of heads on a dime, okay and Y denotes the number of heads on a nickel okay then when you toss a dime and a nickel okay and their x denotes the number of heads on the dime and by the number of heads on the nickel, then they will assume values 0 and 1 okay and so they are both independent, the notion of independence and dependence may be extended to n random variables of an n -dimensional distribution.

In a similar manner we can extend it. So here the number of heads if you calculate the number of heads on a dime and denoted by X and number of heads on a nickel that denote by Y , then either head will come, then number will be 1, if X head does not come, then the value will be 0 okay. So number of heads will be either 0 or 1 okay and they are independent events. So this is the case where random variables X and Y are independent to each other.

(Refer Slide Time: 19:02)

$f(2,2) = \frac{6}{27} \neq f_X(2)f_Y(2) = \frac{12}{27} \times \frac{4}{27} = \frac{4}{27}$
 $f_X(2) = \frac{12}{27} = \frac{4}{9}$
 $f_Y(0) + f_Y(2) = \frac{2}{27} + \frac{6}{27} = \frac{8}{27} \neq f_Y(0)$

Example 3

The joint probability distribution of X and Y is given by

$$f(x, y) = \frac{1}{27}(2x + y), \quad x = 0, 1, 2; \quad y = 0, 1, 2$$

(a) Find the marginal distribution of X and Y .
 (b) Are X and Y independent random variables?

Handwritten calculations and tables:

$f_X(x) = \sum_{y=0}^2 f(x, y)$
 $f_X(0) = \frac{3}{27}$
 $f_X(1) = \frac{6}{27}$
 $f_X(2) = \frac{9}{27}$

$f_Y(y) = \sum_{x=0}^2 f(x, y)$
 $f_Y(0) = \frac{2}{27}$
 $f_Y(1) = \frac{4}{27}$
 $f_Y(2) = \frac{6}{27}$

Joint Probability Table:

X \ Y	0	1	2	$f_X(x)$
0	$\frac{1}{27}$	$\frac{2}{27}$	$\frac{3}{27}$	$\frac{3}{27}$
1	$\frac{2}{27}$	$\frac{3}{27}$	$\frac{4}{27}$	$\frac{6}{27}$
2	$\frac{3}{27}$	$\frac{4}{27}$	$\frac{5}{27}$	$\frac{9}{27}$
$f_Y(y)$	$\frac{2}{27}$	$\frac{4}{27}$	$\frac{6}{27}$	

$\sum_{x=0}^2 f_X(x) = 1$
 $\sum_{y=0}^2 f_Y(y) = 1$
 $f_X(x) \neq f_Y(y)$ (for $x=2, y=2$)

Let us look at the joint probability distribution of X and Y , $f_{xy} = 1/27$ times $2x + y$, $x = 0, 1, 2$, $y = 0, 1, 2$, find the marginal distribution of x and y . So let us first find the marginal distribution of x . So f_{xx} let us find, f_{xx} is $\sum_{y=0}^2 f_{xy}$ okay and x takes the values 0, 1 and 2 okay. So let us form the table for f_{xx} , you can see, we will have to first form the table for all x and y okay.

So let us say like this, this is suppose x and this is y okay. So y takes value 0, 1, 2 okay, x also takes value 0, 1 and 2 okay. So when x is 0, y is 0, x is 0, y 0 $f_{00} = 0$, so this is 0 okay. When x is 0 $y = 1$, x is 0, $y = 1$ so it is $1/27$. When x is 0, $y = 2$ it is $2/27$ okay. When $x = 1$ y is 0, $2/27$. When x is 1, $y = 1$ it is $3/27$. When x is 1, y is 2 it is $4/27$ okay. When x is 2, y is 0 okay, so it is $4/27$. When x is 2 and y is 1, so it is $5/27$.

And when x is 2, y is 2, so it is $6/27$ okay, let us make the total row wise okay. So when you row wise you consider the total okay, then what will happen, you are summing over f_{xy} for $y = 0, 1, 2$ okay, x remains fixed okay, suppose x is 0 okay, so f_{x0} will be $\sum_{y=0}^2 f_{xy}$ okay that means $f_{00} + f_{01} + f_{02}$. So this is $3/27$ okay and when f_{x1} you want to find, f_{x1} will be $\sum_{y=0}^2 f_{1y}$ okay.

So 2, 3, 5, 4, 9, $9/27$ okay and then f_{x2} similarly f_{x2} will be 4, 5, 9, 9, 6, $15/27$ okay, so we have $3 + 9 = 12$, $12 + 15 = 27/27$. So sum of f_{xx} when x varies from 0 to 2 must be $= 1$ okay that is a check, so this is f_{xx} okay. Similarly, we can find f_{yy} , $f_{yy} = \sum_{x=0}^2 f_{xy}$ okay and we have f_{xy} okay. So f_{y0} okay, f_{y0} is $\sum_{x=0}^2 f_{x0}$ okay this okay, so when you take $x = 0$ we have f_{00} , when you take $x = 1$ we have f_{10} .

When you take $x = 2$ we have f_{20} , that is column sum okay. So $0, 2/27, 4/27$ so $6/27$ okay and f_{y1} similarly okay column sum. So $1+3+$ sum of entries in the column. So $1+3, 4, 4+5$ $9/27$ and f_{y2} = you can see $2+4, 6; 6+6, 12/27$ and sum of the values of f_{yy} for $y = 0, 1, 2$ must be $= 1$. So this is $6/27$, this is $9/27$, so $15/27 + 12/27$, so $27/27$ that is $= 1$. So marginal distribution of y . We have this table.

Y here, f_y here okay, y is taking value $0, 1, 2$ okay, when y is 0 it is $6/27$, when y is 1 it is $9/27$, when y is 2 it is $12/27$ okay, so this is marginal density function of y with respect to the joint distribution, this is marginal density function of x , this one f_{xx} = you can write it in the form of the table. For 0 it is $3/27$, for 1 it is $9/27$, for 2 it is $15/27$ like this okay, so this is marginal density function of x . This is marginal density function of y .

Okay are X and Y independent random variables? Now as we have seen in the definition of independence x and y will be independent random variables if $f_{xy} = f_{xx}$, the joint density function must be $=$ the product of the marginal density functions, f_{xy} must be $= f_{xx} * f_{yy}$ for all xy belonging to $0, 1, 2$ for all xy where x to x values from $0, 1, 2$ and y to x value $0, 1, 2$. Now let us see here.

We can notice that f_{00} you can see, f_{00} here is from the table you can see when x is 0 , y is 0 it is 0 okay. So this f_{00} when $x = 0$, $y = 0$ is okay, what is the value of f_{x0} ? $f_{x0} = 3/27$ okay, what is the value of f_{y0} it is $= 6/27$ okay. So $f_{x0} * f_{y0} = 18/27 * 27$ okay. So we get $f_{x0} * f_{y0}$ okay $3/27 * 6/27$ okay so this is $1/9$ and this is $2/9$, so this is $2/81$ okay, which is not $= 0$ and 0 is the value of f_{00} .

So f_{00} is not $= f_{x0} * f_{y0}$ okay and therefore x and y are not independent okay, x and y will be independent provided f_{xy} will be $= f_{xx} * f_{yy}$ for all xy . Now we can see one more thing, f_{22} let us check for one more pair, when x is 2 , y is 2 , so f_{22} is how much here you can see f_{22} is $6/27$ okay. So this is f_{22} , the density function for the joint distribution, when x is 2 , y is 2 , $6/27$, what is f_{x2} ? f_{x2} is $= 15/27$.

$15/27$ means $5/9$ okay and f_{y2} will be $= 12/27$ f_{y2} , so $4/9$ okay. So $5/9 * 4/9 = 20/81$ okay. So f_{22} is $= 6/27$ and this is not $= f_{x2} * f_{y2}$ which is $= 20/81$ okay. So there is one more pair when x is 2 , y is 2 , f_{xy} is not $= f_{xx} * f_{yy}$. So x and y are not independent random variables.

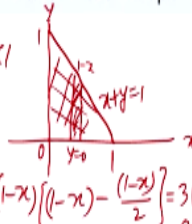

(Refer Slide Time: 29:06)

Example 4

The random variable X and Y have the joint probability density function given by

$$f(x, y) = 6(1 - x - y), \text{ for } x > 0, y > 0, x + y < 1; \text{ and } 0 \text{ otherwise.}$$

Find marginal density function of X and Y . Examine if X and Y are independent.

$$\begin{aligned} f_X(x) &= \int_{-\infty}^{\infty} f(x, y) dy = \int_{y=0}^{1-x} 6(1-x-y) dy, 0 < x < 1 \\ &= 6 \left(y - xy - \frac{y^2}{2} \right) \Big|_{y=0}^{1-x} = 6 \left[(1-x) - x(1-x) - \frac{(1-x)^2}{2} \right] \\ &= 6 \left[(1-x) \left(1-x - \frac{1-x}{2} \right) \right] = 3(1-x)^2, 0 < x < 1 \end{aligned}$$

Let us take now the case of continuous random variable section Y . So the random variable section Y have the joint probability density function given by $f_{xy} = 6$ times $1 - x - y$ when x is > 0 , y is > 0 , $x+y < 1$ and 0 otherwise. So let us see in which part of the xy plane f_{xy} is nonzero. So this is the part, this is 1 , this is 1 , this part okay. This is $x + y = 1$, this is x axis and this is y axis okay.

So x is > 0 here, y is > 0 and $x + y$ is < 1 , now we want to find the marginal density function of x and marginal density function of y . So f_{xx} we have to find, $f_{xx} =$ when x will be > 0 , y is > 0 . So f_{xx} is integral/- infinity to infinity okay, $f_{xy} dy$ okay. Now in this region f_{xy} is given by 6 times $1-x-y$. So this will be integral over y varies from, we have to integrate over y , x remains constant.

So we have to take a vertical step, along the vertical step x is constant, y varies and y varies from 0 to $1-x$ okay. So y varies from 0 to $1-x$ and we have 6 times $1-x-y$ dy okay and this is the case when x lies between 0 and 1 . If x lies elsewhere f_{xy} will be 0 . So this is $= 6$ times $x - x^2/2 - xy$ and when we put the limits $y = 0$ to $y = 1-x$ what we get is 6 times $x - x^2/2 - x(1-x)$ and when we put the limits $y = 0$ to $y = 1-x$ what we get is 6 times $x - x^2/2 - x(1-x)$ okay.

So we should write here $y - x * y - y^2/2$ okay. So $y = 1-x$, so we have $1-x$ here and then x times $1-x$ and we have $-1-x$ whole square/2, okay, when y is 0 this is 0 okay. So this is how much, we can take $1-x$ common, so 6 times $1-x$ and what we get inside $1-x$ okay, $1-x - 1-x/2$

okay. So $1-x/2$ that is the value of the expression inside the bracket. So this is 3 times $1-x$ whole square.

So this is the f_{xx} , the value of f_{xx} when $0 < x < 1$. So we can write the marginal density function here.

(Refer Slide Time: 32:21)

Marginal density function

$$f_x(x) = \begin{cases} 3(1-x)^2, & 0 < x < 1 \\ 0, & \text{otherwise} \end{cases}$$

$$f_y(y) = \int_0^{1-y} f(x,y) dx = \int_0^{1-y} 6(1-x-y) dx$$

$$= 6 \left(x - \frac{x^2}{2} - xy \right)_0^{1-y} = 6 \left((1-y) - \frac{(1-y)^2}{2} - y(1-y) \right)$$

$$= 6(1-y) \left(1 - \frac{(1-y)}{2} - y \right) = 3(1-y)^2$$

$$f_y(y) = \begin{cases} 3(1-y)^2, & 0 < y < 1 \\ 0, & \text{otherwise} \end{cases}$$

X and y are not independent

check $f(x,y) = f_x(x)f_y(y)$

$$f(x,y) = \begin{cases} 6(1-x-y), & x+y < 1 \\ 0, & \text{otherwise} \end{cases}$$

$$f_x(x)f_y(y) = \begin{cases} 9(1-x)^2(1-y)^2, & 0 < x < 1, 0 < y < 1 \\ 0, & \text{otherwise} \end{cases}$$

$f(x,y) \neq f_x(x)f_y(y)$

Marginal density function as $f_{xx} = 3$ times $1-x$ whole square when $0 < x < 1$ and 0 otherwise okay, now we, let us find the other marginal density function, that is marginal density function of y okay. When we want to find the marginal density function of y , now what will happen, we will integrate f_{xy} with respect to x , keeping y fixed okay. So y is fixed along the horizontal strip okay.

So when y is fixed x varies from 0 to $1-x$ okay, x varies from 0 to $1-y$, so we have this $f_{yy} =$ integral over 0 to $1-y$, $f_{xy} dx$ okay. So this is 0 to $1-y$ and 6 times $1-x-y$ dx okay. So again what we will have, we will have the integral as 6 times $x - x^2/2$ okay $-x * y$ right and the limits are 0 $1-y$ and the values of y vary from 0 to 1 okay, because we have this region and we are taking a horizontal strip in this region.

So y is fixed here, y varies from 0 to 1 okay. So this will be again 6 times $1-y - 1-y$ whole square/2 $- y * 1-y$. So what we will get this is 6 times $1-y$ we can take common and then what we will get $1-y/2 - y$ okay, which is 3 times $1-y$ whole square, $0 < y < 1$. So $f_{yy} = 3$ times $1-y$ whole square $0 < y < 1$ and 0 otherwise, okay. Now we have to answer whether the variables x and Y are independent or not.

So we have to see f_{xy} even if they are independent, f_{xy} must be $= f_{xx} * f_{yy}$ okay. So let us check this. Let us check whether it is true or not okay. So $f_{xy} =$ we are given that $f_{xy} = 6$ times $1-x-y$ when x is > 0 , y is > 0 and $x+y$ is < 1 and 0 otherwise. Here what is happening is f_{xy} we have seen $f_{xy} = 6$ times $1-x-y$, x is > 0 , y is > 0 $x+y < 1$ okay and 0 otherwise and what we find is that $f_{xx} * f_{yy}$ okay.

This is $= 3$ times $1-x$ whole square $* 3$ times $1-y$ whole square, so 9 times $1-x$ whole square $* 1-y$ whole square when $0 < x < 1$, $0 < y < 1$ okay, in this region and 0 otherwise. Okay so in the common portion, this portion, see when $0 < x < 1$ and $0 < y < 1$ okay in this square okay and this region is a part of this okay. So over this region where x is > 0 , y is > 0 $x+y < 1$ f_{xy} is 6 times $1-x-y$ while $f_{xx} * f_{yy}$ is 9 times $1-x$ whole square $* 1-y$ whole square.

So they are not equal okay, so it turns out that f_{xy} is not $= f_{xx} * f_{yy}$ when x is > 0 , y is > 0 and $x+y$ is < 1 okay. So they are not independent okay. So x and y are not independent okay. So we have found the marginal density function of x and y and also we have seen that x and y are not independent. So with this I would like to end my lecture. Thank you very much for your attention.
