Lecture – 06
Complex Integration

Hello friends, welcome to my lecture on complex integration, why do we study complex integration; the integration in the complex plane is important because there are many real integrals which can be evaluated by complex integration while the usual methods of real integral calculus failed in those cases, so and further in the complex integration, we are able to prove some basic properties of analytic functions like their existence of higher order derivatives which will be otherwise difficult to establish.

(Refer Slide Time: 01:06)

The integration in the complex plane is important because there are many real integrals which can be evaluated by complex integration while the usual methods of real integral calculus fail. Further, by complex integration we are able to prove some basic properties of analytic functions such as the existence of higher order derivatives which will be otherwise difficult to establish.

Line integral in the complex plane

Let $z(t) = x(t) + iy(t)$, $a \leq t \leq b$ be the parametric form of a curve C in the complex z -plane. We assume that the curve C is smooth i.e. $z(t)$ is continuously differentiable $\forall t \in [a, b]$ and $\dot{z}(t) \neq 0$ for any t . The length 's' of the curve C is given by

$$s = \int_a^b \sqrt{(\dot{x}(t))^2 + (\dot{y}(t))^2} dt$$

$\dot{z}(t) = \frac{dz}{dt}$

Let us consider first the line integral in the complex line, so let us consider the parametric representation of a curve C in the complex z plane, let $z(t) = x(t) + iy(t)$ $a \leq t \leq b$ be the parametric form of a curve C in the complex z plane, let us assume that the curve C is smooth that is the $z(t)$ function is continuously differentiable for all t belonging to the closed interval ab and $dz/dt \neq 0$, \dot{z} means $dz/dt \neq 0$.

The length of the curve we know; the length of the curve as is then given by $S = \int_a^b \sqrt{dx/dt^2 + dy/dt^2} dt$.

(Refer Slide Time: 01:51)

Then C is a rectifiable curve. Further, the positive direction along C corresponds to the sense of increasing values of t .

Let $f(z)$ be a continuous function at each point of C . We subdivide the interval $a \leq t \leq b$ by means of points

$$t_0 (= a), t_1, t_2, \dots, t_{n-1}, t_n (= b)$$

where $t_0 < t_1 < t_2 < \dots < t_{n-1} < t_n$. To this subdivision there corresponds a subdivision of C by points

$$z_0, z_1, z_2, \dots, z_{n-1}, z_n (= z)$$

where $z_j = z(t_j)$, $j = 0, 1, \dots, n$.

$$z(t) = x(t) + iy(t), \quad a \leq t \leq b$$

$$z(t_j) = x(t_j) + iy(t_j), \quad j = 0, 1, \dots, n$$

The curve C is then called the rectifiable curve, now the positive direction along C corresponds to the sense of increasing values of t , the direction in which the values of t increase, okay, a set with the positive sense along the curve C . Let us consider a continuous function fz at each point of C , let us say fz is a continuous function at each point of C , we sub divide the interval ab okay the interval; close interval ab by means of these $n + 1$ points.

$T_0 = a, t_1, t_2, \dots, t_{n-1}$ and $t_n = b$, okay, so this is your suppose interval ab , let us divided it into n parts, okay, so $t_0 < t_1 < t_2 < \dots < t_{n-1} < t_n$, now we have $z_t = x_t + iy_t$, where $a \leq t \leq b$, so corresponding to these values of t ; $t_0, t_1, t_2, t_3, \dots, t_{n-1}, t_n$, there will be the values of z , okay, so let us say $z_{t_i} = z_i$, where i varies from; i goes from 0 to n , okay so that means $z_{t_0} = z_0, z_{t_1} = z_1, z_{t_n} = z_n$.

(Refer Slide Time: 03:34)

Figure : Fig.1

On each portion of a subdivision of C , let us choose a point, say, ζ_1 between z_0 and z_1 , ζ_2 between z_1 and z_2 and so on. Then we form the sum

$$S_n = \sum_{m=1}^n f(\zeta_m) \Delta z_m, \quad (1)$$

where $\Delta z_m = z_m - z_{m-1}$, $m = 1, 2, \dots, n$

Then, these curve; this curve let us say this curve C okay, z_0 is point here, z_1 is the point here, z_2 here and this is your z , z is; this is z_n , okay. Now, on each portion of a subdivision, so this divided the curve into n parts on each portion of a subdivision of C , let us choose a point, say ζ_1 between z_0 and z_1 , so here we choose ζ_1 between z_1 and z_2 , we choose a point ζ_2 and so on which mean, z_{m-1} and z_m , we choose a point ζ_m in a completely arbitrary manner and so on.

So, and then we form S sum, okay S_n , so S_n will be $\sum_{m=1}^n$; because in the n th interval, z_{n-1} to z_n ; z_{n-1} to z_n we choose ζ_n okay, so then and since f is a continuous function at each point of C , so we can find the values of f , at ζ_1 , ζ_2 , ζ_m and ζ_n and then multiply them by Δz_m , $f(\zeta_m)$ is multiplied by Δz_m , where Δz_m is $z_m - z_{m-1}$, okay, this is $z_m - z_{m-1}$, this is Δz_m and the magnitude of Δz_m .

Mod of Δz_m , this is the distance between z_m and z_{m-1} , okay, so the lines of this curve, okay, mod of Δz_m is the length of this curve, so you multiply $f(\zeta_m) / \Delta z_m$ and form the sum from over sigma over m from 1 to n , so S_n you get, $\sum_{m=1}^n f(\zeta_m) \Delta z_m$.

(Refer Slide Time: 05:33)

This we do for each $n = 2, 3, \dots$ in a completely independent manner but in such a way that the greatest of $|\Delta z_m| \rightarrow 0$ as $n \rightarrow \infty$. This gives a sequence of complex numbers S_2, S_3, S_4, \dots . The limit of the sequence as $n \rightarrow \infty$ is called the line integral of $f(z)$ along the oriented curve C and is denoted by

$$\int_C f(z) dz.$$

The curve C is called the path of integration.

$$\int_C f(z) dz = \lim_{\substack{n \rightarrow \infty \\ \max_{1 \leq m \leq n} |\Delta z_m| \rightarrow 0}} S_n$$

And this we do for each value of n , $n = 2, 3$ and so on, we have divided into n parts, so let us start with $n = 2$, we divide first into 2 parts, okay, form S_n , S_n means from we get S_2 , okay for $n = 2$, we get a 2, for $n = 3$ similarly, we get S_3 and so on, okay. So, this we do in a completely independent manner but in such a way that when you sub divide the curve C into n parts, let us and n increase, n goes to infinity.

We do this in such a way that the maximum of mod of Δz_m , okay goes to 0, as n goes to infinity that is means the maximum arch length, maximum cord length okay, Δz mod of Δz_m is the distance between z_m and z_{m-1} , okay, maximum of mod of Δz_m tends to 0 as n goes to infinity, then the sequence of complex number S_2, S_3 , and so on that converges to the integral of fz along C , okay.

The limit of the sequence then goes to infinity and it is called the line integral of fz along the oriented curve C , we are considering the orientation of the curve C , okay, we have decided to take the sense along the curve C , okay, so it is called an orientated curve, so oriented curve C and we denoted by integral over C $fz dz$, the curve C is called the path of the integration. So, integral over C , $fz dz$ here is the limit of S_n as n goes to infinity.

But in such a way that maximum of mod of delta z_m , okay, when $m \rightarrow \infty$, $z_m \rightarrow z$ goes to 0, okay, so this is how be the definition of the line integral of fz , okay is exactly the same as we do it in the case of real integrals.

(Refer Slide Time: 07:39)

Existence of the complex line integral

Let $f(z) = u(x, y) + iv(x, y)$, $z = x + iy$, $\Delta z = \Delta x + i\Delta y$

and $\zeta_m = \xi_m + i\eta_m$, $\Delta z_m = z_m - z_{m-1}$, $\Delta z_m = \Delta x_m + i\Delta y_m$

Then (1) yields

$$S_n = \sum_{m=1}^n \{u(\xi_m, \eta_m) + iv(\xi_m, \eta_m)\}(\Delta x_m + i\Delta y_m)$$

$$S_n = \sum_{m=1}^n f(\zeta_m) \Delta z_m$$

$$= \sum_{m=1}^n \left[u(\xi_m, \eta_m) + i v(\xi_m, \eta_m) \right] (\Delta x_m + i \Delta y_m)$$

So, now let us discuss the existence of the complex line integral, fz is a complex function, so let us take the real and imaginary parts of fz as $u(x, y)$ and $v(x, y)$, so fz is $u(x, y) + iv(x, y)$, let us ζ_m is a point which; lie between z_{m-1} and z_m , so we can take it as $\xi_m + i\eta_m$ and Δz_m ; z is $x + iy$, so Δz is $\Delta x + i\Delta y$, so Δz_m which is the $z_m - z_{m-1}$; Δz_m is $\Delta x_m + i\Delta y_m$, okay.

So, Δz_m because of Δz means $\Delta x + i\Delta y$, we write Δz_m as $\Delta x_m + i\Delta y_m$ okay, if z_m is say $x_m + i y_m$ and z_{m-1} is $x_{m-1} + i y_{m-1}$, then $\Delta y_m = y_m - y_{m-1}$, so then we can get $\Delta x_m \Delta y_m$, so Δz is $\Delta x + i\Delta y$, then the equation 1 yields, we get the following, equation 1, this equation, $S_n =$; we have $S_n = \sum_{m=1}^n f(\zeta_m) \Delta z_m$, okay, this gives you $\sum_{m=1}^n f(\zeta_m)$ will give you $u(\xi_m, \eta_m)$.

Because this ζ_m is $\xi_m + i\eta_m$, its real part is ξ_m , imaginary part is η_m , so we get $u(\xi_m, \eta_m) + iv(\xi_m, \eta_m)$, this multiplied by Δz_m which is $\Delta x_m + i\Delta y_m$, okay, so we multiply this expression by $\Delta x_m + i\Delta y_m$ and sum over $m = 1$ to n .

(Refer Slide Time: 10:11)

$$S_n = \sum_{m=1}^n u(\xi_m, \eta_m) \Delta x_m - \sum_{m=1}^n v(\xi_m, \eta_m) \Delta y_m + i \left\{ \sum_{m=1}^n u(\xi_m, \eta_m) \Delta y_m + \sum_{m=1}^n v(\xi_m, \eta_m) \Delta x_m \right\} \quad (2)$$

All these sums are real and since f is continuous, the real functions $u(x, y)$ and $v(x, y)$ are also continuous. As $n \rightarrow \infty$, maximum of $|\Delta z_m| \rightarrow 0$ and so also maximum of Δx_m and Δy_m will approach zero. Hence each sum in (2) can be replaced by a real line integral.

$$\lim_{n \rightarrow \infty} S_n = \int_C f(z) dz = \int_C u(x, y) dx - \int_C v(x, y) dy + i \left(\int_C u(x, y) dy + \int_C v(x, y) dx \right)$$

$|\Delta z_m| = \sqrt{(\Delta x_m)^2 + (\Delta y_m)^2}$
 $\max |\Delta z_m| \rightarrow 0 \Rightarrow \Delta x_m \rightarrow 0, \Delta y_m \rightarrow 0$

Then if you these 2 vectors; this vector and this vector; this expression and this expression, what you get is this and $u^2 + v^2 = -1$, okay, we get $\sum_{m=1}^n \eta_m \Delta x_m - \sum_{m=1}^n \eta_m \Delta y_m + i \sum_{m=1}^n \eta_m \Delta y_m + \sum_{m=1}^n \eta_m \Delta x_m$. Now, all these sums, okay, all these sums are real, you can see, $u(x, y)$ is a real function, Δx is also real.

So, $u(x, y) \cdot \Delta x$ is the real quantity, so these; all these expressions; this, this, this and this, they are all real sums okay, since f is a continuous function, so its real and imaginary parts are continuous, $u(x, y)$ and $v(x, y)$ are continuous functions and therefore, as n goes to infinity, when maximum of mod of Δz_n goes to 0, maximum of mod of Δx_m and mod of Δy_m also goes to 0, you can see, we have $\Delta z_m =$ this, okay.

So, Δz_m goes to 0, mod of Δz_m will be what; under root $\Delta x_m^2 + \Delta y_m^2$, okay so when maximum of mod of Δz_m goes to 0, when this goes to 0, okay, Δx_m and Δy_m , they will also tend to 0, okay, so they will also 0 and hence each sum here can be replaced by a real integral, so limit n tends to infinity, S_n gives you integral over C $f(z) dz$ which is $= \int_C u(x, y) dx - \int_C v(x, y) dy + i \int_C u(x, y) dy + \int_C v(x, y) dx$.

Because we have delta y here, delta ym, so we get $u \, xy \, dy + \text{integral over } v \, xy$; integral over C $v \, xy$, okay, so the evaluation of a complex function, okay, a complex integral reduces to a evaluation of 4 real integrals, this integral, this integral, this integral and this integral.

(Refer Slide Time: 12:57)

Thus,

$$\lim_{n \rightarrow \infty} S_n = \int_C f(z) \, dz$$

$$= \int_C u \, dx - \int_C v \, dy + i \left[\int_C u \, dy + \int_C v \, dx \right]$$

$$\Rightarrow \int_C f(z) \, dz = \int_a^b u \frac{dx}{dt} \, dt - \int_a^b v \frac{dy}{dt} \, dt + i \left[\int_a^b u \frac{dy}{dt} \, dt + \int_a^b v \frac{dx}{dt} \, dt \right],$$

where $u = u(x(t), y(t))$ and $v = v(x(t), y(t))$.

Handwritten notes:

- $\int_C u(x,y) \, dx = \int_a^b u(x(t), y(t)) \frac{dx}{dt} \, dt$
- $C: z(t) = x(t) + iy(t)$, $a \leq t \leq b$
- $\int_C f(z) \, dz = \int_a^b \left[u(x(t), y(t)) + i v(x(t), y(t)) \right] \frac{d}{dt} (x(t) + iy(t)) \, dt$
- $\int_C f(z) \, dz = \int_a^b f(z(t)) \dot{z}(t) \, dt$

Now, and evaluation of these integrals, these real integrals; these 4 integrals; this one, this one, this one and this one can be done easily by using the parametric form of the curve C, okay so we replace integral over C $u \, dx$ y integral over C $u \, dx$ over dt , dt , integral over C $u \, xy \, dx$ will be written as integral over a to b, $u \, x \, t \, y \, t \, dx$ over dt , dt okay and we know that the parametric form of a curve C is $z(t) = x(t) + iy(t)$ where $a \leq t \leq b$.

So, this is how we can evaluate the integral of u with respect to x , integral of v we can find, with respect to y and so on, okay so these 4 real integrals can be determined and we get the integral over C $f(z) \, dz$. Now, briefly this can be expressed further in a simpler form.

(Refer Slide Time: 14:09)

Briefly, the above representation can also be expressed as

$$\int_C f(z) dz = \int_a^b f(z(t)) \dot{z}(t) dt$$

$$\begin{aligned} \dot{z}(t) &= \frac{dz}{dt} = \frac{dx}{dt} + i \frac{dy}{dt} \\ f(z) &= u(x, y) + i v(x, y) \\ f(z(t)) &= u(x(t), y(t)) + i v(x(t), y(t)) \end{aligned}$$

where $z(t) = x(t) + iy(t)$.

Example 1

Consider

$$\int_C \frac{1}{z - z_0} dz$$

$$\begin{aligned} |z - z_0| &= a \\ z - z_0 &= a e^{it}, \quad 0 \leq t < 2\pi \end{aligned}$$

where C is the circle of radius a and center z_0 in the counterclockwise sense.

we may write $z := z - z_0 = a e^{it}$, $0 \leq t \leq 2\pi$.

You can write, actually this is nothing but integral over a to b $f(z) \dot{z} dt$, this is $\dot{z} dt$, $\dot{z} dt$ is dz/dt , okay and dz/dt is $dx/dt + i dy/dt$, okay, you can see $f(z)$, $f(z) = u(x, y) + i v(x, y)$, so $f(z(t))$ will be $u(x(t), y(t)) + i v(x(t), y(t))$, okay, so when you multiply $f(z(t))$ okay by $\dot{z} dt$ okay, and $i^2 = -1$, okay and integrate over a to b , what you get is the expressions this one, okay, this is nothing but this quantity, this is nothing but integral over a to b $u(x(t), y(t)) dx + v(x(t), y(t)) dy$ okay.

If you multiply these 2, you get this right hand side, so this is and this is nothing but integral over a to b $f(z(t)) \dot{z} dt$, so integral over C , $\int_C f(z) dz$ by using the parametric form of the complex of the curve C can be; the complex integration can be replaced by a definite integration, so we get this. Now, let us first, for example, consider integral over C $\frac{1}{z - z_0} dz$, where C is the circle of radius a and centre z_0 in the counter, so we are moving along the curve C in the counter clock wise direction, okay.

What we do is; let us write the parametric form of the curve C , we can write the equation of the curve C is what; $|z - z_0| = a$, okay because if a is the radius and z_0 is the centre we know that the curve C can be written as $|z - z_0| = a$, so we write in the parametric form, we write it as $z - z_0 = a e^{it}$, okay and we are moving in the counter clockwise direction, so we have $0 \leq t < 2\pi$, okay.

(Refer Slide Time: 17:22)

Then the given integral

$$\int_C \frac{1}{z - z_0} dz = 2\pi i.$$

$$z - z_0 = a e^{it}$$

$$\frac{dz}{dt} = a e^{it} \cdot i$$

$$z - z_0 = a e^{it}, 0 \leq t \leq 2\pi$$

$$f(z) = \frac{1}{z - z_0}$$

$$\int_C f(z) dz = \int_a^b f(z(t)) \frac{dz}{dt} dt$$

$$= \int_0^{2\pi} \frac{1}{a e^{it}} \cdot a e^{it} \cdot i dt$$

$$= i \int_0^{2\pi} 1 dt = \underline{\underline{2\pi i}}$$

Figure : Fig:2

So, you can see here, the figure here you can see, this is your figure, okay we are moving the centre is z_0 , radius is a , if you take the point P here, θ , I have written $z - z_0 = a e$ raised to the power $i t$, this $\theta = t$ for us, okay. So, you can see t is 0 here, okay, here t is 0 and it moves from 0 to 2π , when we go in the counter clockwise direction, okay. So, integral over C $fz dz$ we have seen, this = integral over a to b $fz \frac{dz}{dt} \cdot dt$, okay.

So, replacing z by $z(t)$ in the equation of the function fz , we will get $fz(t)$, fz is given as 1 over $z - z_0$ here, okay, the complex form of the function fz is 1 over $z - z_0$, so let us use the parametric form, so when we use the parametric form, fz becomes $fz(t)$ and $fz(t)$ will be = integral limits of 0 to 2π , okay, $fz(t)$ will be 1 over $a e$ raised to the power $i t$, okay, $z - z_0$ is $a e$ raised to the power $i t$ and dz/dt , let us find $z - z_0 = a e$ raised to the power $i t$.

When we differentiate with respect to t , dz/dt , z_0 is a constant, so if derivative with respect to t is 0 , so we get $a e$ to the power $i t \cdot i$, okay, so the value here $a e$ to the power $i t \cdot i dt$, now e to the power $i t$ is never 0 , so we can cancel out and what we get is; i times integral 0 to 2π dt , so we get $2\pi \cdot i$, this is how we get the value of the given integral using the parametric form of the complex; parametric form of the curve C .

(Refer Slide Time: 19:53)

Example 2

Let

$$f(z) = |z|.$$

$$\begin{aligned} \int_{BCA} f(z) dz &= \int_{\pi}^0 f(z(\theta)) \frac{dz}{d\theta} d\theta \\ &= \int_{\pi}^0 r \cdot r e^{i\theta} (-i) d\theta \\ &= -i r^2 \int_{\pi}^0 e^{i\theta} d\theta \end{aligned}$$

Figure : Fig.3

$$\begin{aligned} \int_{ADB} f(z) dz &= \int_0^{\pi} f(z(\theta)) \frac{dz}{d\theta} d\theta \\ &= \int_0^{\pi} |z| dz \\ &= \int_0^{\pi} r \cdot r e^{i\theta} (i) d\theta \\ &= i r^2 \int_0^{\pi} e^{i\theta} d\theta \\ &= i r^2 \left[\frac{e^{i\theta}}{i} \right]_0^{\pi} \\ &= r^2 (e^{i\pi} - e^{i0}) \\ &= r^2 (-1 - 1) \\ &= -2r^2 \end{aligned}$$

for ADB
Let $z = r e^{i\theta}$
then $\frac{dz}{d\theta} = r e^{i\theta} i$
 $|z| = r$
 $\frac{dz}{d\theta} = r e^{i\theta} i$

Let us take another problem, $fz = \text{mod of } z$, okay.

(Refer Slide Time: 19:59)

a) Integrating $f(z)$ along the semi-circle ABD

$$\text{Then } \int_{ADB} f(z) dz = i r^2 \int_{-\pi/2}^{\pi/2} e^{i\theta} d\theta$$

$$\begin{aligned} &= i r^2 \left[\frac{e^{i\theta}}{i} \right]_{-\pi/2}^{\pi/2} = r^2 \left(e^{i\pi/2} - e^{-i\pi/2} \right) \\ &= r^2 (i - (-i)) \\ &= 2i r^2 \end{aligned}$$

In the particular case $r=1$, we get the value $2i$.
Unit circle $\lim_{r \rightarrow 1} |z|=1$

$$\begin{aligned} e^{i\theta} &= \cos\theta + i \sin\theta \\ e^{i\pi/2} &= \cos\frac{\pi}{2} + i \sin\frac{\pi}{2} \\ &= 0 + i = i \\ e^{-i\pi/2} &= \cos\frac{\pi}{2} - i \sin\frac{\pi}{2} \\ &= 0 - i = -i \end{aligned}$$

So, we have to integrate fz along the semi-circle ABD here, okay this semi-circle ABD, okay ABD, okay this semicircle ABD, so we have to integrate along the semi-circle ABD and it is centre is that origin, okay, radius we can take to be r , okay, so, we have to integrate fz along the semi-circle ABD

(Refer Slide Time: 20:24)

b) Integrating along the semi-circle BCA

$$\begin{aligned}
 \int_{BCA} f(z) dz &= i r^2 \int_{\pi/2}^{3\pi/2} e^{i\theta} d\theta \\
 &= r^2 \left[\frac{e^{i\theta}}{i} \right]_{\pi/2}^{3\pi/2} = r^2 \left(e^{3i\pi/2} - e^{i\pi/2} \right) \\
 &= r^2 (-i - i) = -2i r^2
 \end{aligned}$$

Thus, in the particular case $r=1$, we get

$$\int_{BCA} f(z) dz = -2i \checkmark$$

$e^{i(3\pi/2)} = \cos \frac{3\pi}{2} + i \sin \frac{3\pi}{2} = 0 + i(-1) = -i$
 $e^{i(\pi/2)} = 0 + i(1) = i$
 $= -i - i = -2i$

And then in the second case, we have to integrate along the semi-circle BCA, so semi-circle BCA is this one, okay, this is semicircle BCA, so first we integrate along ABD, okay, so let us see we have $z = \text{mod of } z$, so we have to integrate $fz dz$ ADB, okay so what we will do is; $fz = \text{mod of } z$, so integral ADB mod of $z dz$, we have to find okay, so let us write $dz = \text{let } z \text{ be } = r e^{i\theta}$ to the power $i\theta$.

So, then mod of $z = r$, okay, now you can see here, θ varies from $\theta = -\pi/2$ here and $\theta = \pi/2$ here, so when you integrate mod of z along ADB, what you get; integral over; we can write $z = r e^{i\theta}$ and θ varies from $-\pi/2$ to $\pi/2$, in case of ADB, for ADB $z = r e^{i\theta}$ where θ varies from $-\pi/2$ to $\pi/2$, so $-\pi/2$ to $\pi/2$ and mod of $z = r$, so we get r times and then $dz/d\theta * d\theta$.

Because fz is integral over limits of θ , say α to β $fz \theta dz/d\theta * d\theta$ okay by over article on complex line integral, so this will be how much; this is $dz/d\theta$ will be $= r e^{i\theta}$ to the power $i\theta * i d\theta$, okay so this is $-\pi/2$ to $\pi/2$ r times $r e^{i\theta}$ to the power $i\theta * i d\theta$, r square we can write it outside, I also we can write outside, so $-\pi/2$ to $\pi/2$ $e^{i\theta}$ to the power $i\theta d\theta$, okay.

Now, so then integral over ADB, $fz dz = I r$ square, this is what we get, okay, so now, $e^{i\theta}$ to the power $i\theta$ we know it is $\cos \theta + i \sin \theta$, okay, so $e^{i\pi/2}$ is $\cos \pi/2 + i \sin$

$\pi/2$ and this $=$; $\cos \pi/2$ is 0, $\sin \pi/2$ is 1, so we get i here and similarly, e to the power $-i\pi/2 = \cos \pi/2 - i \sin \pi/2$, so this is $-i$, so what do we get here; r^2 times $i - -i$ and we get $2i r^2$.

So, in the particular case, $r=1$, okay, we get the value $2i$, okay, $\text{mod of } z = r$ we have taken, so $\text{mod of } z = 1$ here, okay, $\text{mod of } z = 1$ is called the unit circle, so if you consider the unit circle, I mean to say that integral of $\text{mod of } z$ along $ADB = 2i$. Now, let us consider the case of BCA , okay BCA is this, okay, so here, when you move in this direction, θ increases from 0 to $\pi/2$, then 2π and then $3\pi/2$, okay.

So, now we shall integrate along; when you move along BCA , okay then what you get is this, we start with $\theta = \pi/2$ and go up to $\theta = 3\pi/2$, okay, fz θ will be $= \text{mod of } z$, $\text{mod of } z = r$ so r and dz/θ ; $d\theta$ we have already have found, $r e$ to the power $i\theta * i d\theta$, okay, so what do we get is; i times r^2 $\pi/2$ to $3/2$ e to the power $i\theta d\theta$, okay. So, this will give you this one, okay integral over BCA $fz dz = i r^2$ and this is $= r^2$ times.

So, this i cancels with this i and what we get; r^2 times e to the power $3i\pi/2 - e$ to the power $i\pi/2$, e to the power $3i\pi/2 = \cos 3\pi/2 + i \sin 3\pi/2$, we know that $\cos 3\pi/2$ is 0 and $\sin 3\pi/2$ is $\sin \pi + \pi/2$, so $-\sin \pi/2$, so we get i times -1 , so this is $-i$, so this is $= r^2$ times $-i$ and e to the power $i\pi/2$ is $\cos \pi/2 + i \sin \pi/2$, so then i , so we get $-i$, so we get $-2i r^2$, okay.

And thus in the particular case, $r = 1$, okay we get, $-2i$, okay, so when you integrate along the semicircle BCA where the circle has radius 1 is that the value $-2i$, okay.

(Refer Slide Time: 28:45)

Example 3

Integrate $f(z) = \Re(z)$ along the

a) line segment from $z = 0$ to $z = 1 + i$.

$$\begin{aligned} \int_C f(z) dz &= \int_C x dz \\ &= \int_C x(dx + i dy) \\ &= \int_0^1 x(1+i) dx \\ &= (1+i) \int_0^1 x dx = (1+i) \left[\frac{x^2}{2} \right]_0^1 \\ &= \frac{1+i}{2} \end{aligned}$$

Let us consider one more example, $fz = \text{real part of } z$, okay, so let z be $= x + iy$, so then real part of $z = x$ and hence $fz = \text{real part of } z$ means x , okay, we are considering the line segment from $z = 0$ to $z = 1 + i$, so this is $z=0$, origin here $z = 0$ and $z = 1 + i$ means, $1 + i$ point, okay, so $1 + i$ point, this is $x = 1$, this is $y = 1$, okay, so $1 + i$ point, we are going from 0 to $1 + i$ direct, okay, so this is the line segment where we are integrating.

And we are integrating from $z = 0$ to $z = 1 + i$, this is nothing but equivalent to $z = 1 + i$, okay, so integral over $fz dz$ here will be $=$; okay, fz is $x dz$, okay, now what do we do; $z = x + iy$, okay, so we can write here $dz =$; $z = x + iy$, so $dz = dx + i dy$, so I can write it as integral over C $x dx + i dy$, okay, the equation of the line, okay the line joining 00 to 11 is given by $y = x$, okay, so $dy = dx$, okay.

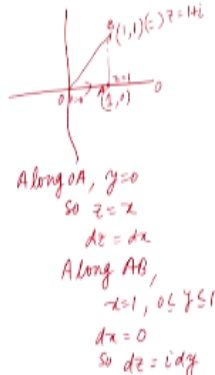

So, I can write integral over x and then $dx + i dx$ that is $1 + i dx$, okay and x varies from 0 to 1 , okay, so $0 \leq x \leq 1$, okay line segment joining 00 to 11 is given by $y = x$, where $0 \leq x \leq 1$ from 0 to 1 , so we get $1 + i$ is a constant, we can write it outside and 0 to 1 $x dx$ we get, so this $1 + i$ times $x^2/2$, 01 , okay, so $1 + i$ times $1/2$, so I can write $1 + i$; here what I have done is parametric form of the curve C I have taken, where in place of t I have written x , okay.

So, actually I am considering parameter t to be $= x$ here, so x here we have taken as t or you can; and y is also $= t$, okay, so this is same as the complex integration, we have taken instead of the

parameter t , we have taken x and $y = x$ and y is also $= t$, so this is what we get, when we integrate from $z = 0$ to $z = 1 + i$ along the line segment.

(Refer Slide Time: 32:49)

b) real axis from 0 to 1 and then vertically to $1 + i$. (Path C_2).

$$\begin{aligned} \int_C f(z) dz &= \left(\int_{OA} + \int_{AB} \right) f(z) dz \\ &= \int_{OA} f(z) dz + \int_{AB} f(z) dz \\ &= \int_0^1 x dx + \int_0^1 x(i dy) \\ &= \left(\frac{x^2}{2} \right)_0^1 + \int_0^1 i dy, \text{ as } x=1 \text{ along } AB \\ &= \frac{1}{2} + i(y)_0^1 = \frac{1}{2} + i \end{aligned}$$

Along OA, $y=0$
So $z=x$
 $dz=dx$
Along AB,
 $x=1, 0 \leq y \leq 1$
 $dx=0$
So $dz=i dy$

Now, in the second case, we integrate along this one, this is your $z=0$, this $z=1$, $1+0$ point and this is your $1+1$ point, okay which is same as $z=1+i$, okay, so we have to move along the real axis, this is real axis, okay we have to move along the real axis from 0 to $z=0$ to $z=1$, this is $z=0$, this is $z=1$ and then vertically $2+1+i$, from $z=1$ to $z=1+i$, we are moving vertically, okay. So, integral over C , $fz dz =$ integral over; let us say this is I can write it as some let us say A point and this is B point.

So, integral over $OA +$ integral over $OB fz dz$, okay, so integral over $OA fz dz$, but when we go from O to A , okay along the real axis, along OA , $y=0$, okay, so $z=x$, $z=x$ means fz is real part of z , real part of z is x , so x times, $dz=dx$ and x varies from 0 to 1 , okay, so 0 to $1 x dx$ we have. Now, along; this is AB , we are going from O to A , then A to B , okay, so AB means now, along AB what is happening is; $x = \text{constant}$, $x=1$, okay.

And $x=1$ and y varies from 0 to 1 , okay, so when $x=1$, $dx=0$, so $dz=i dy$, okay, so we will have here x times $i dy$ and y varies from 0 to 1 , okay, so we get here $x=1$, we will put there, okay so we will get here $x^2/2, 0$ to 1 and then i times $x=1$ along AB , so we have here

iota dy, $x = 1$ along AB, okay, so what you get here; so we get here, $1/2$ and then we had I times, we get $1 + 2/i$.

Now, you can see here, the value that we obtained by integrating along the line segment from $z = 0$ to $z = 1 + I$ that was $1 + i/2$, while the value that we have got from y integrating from 0 to A and then A to B is $1/2 + I$, so both the values are not same, okay and therefore, the value of the integral is not does not always depend on the end points, it also depends on the geometric shape of the path.

So, we shall see later on because this function $fz = \text{real } z$, it is not analytic, okay, so that is why such a thing has happened, whenever a function fz is analytic, okay along whatever in the region of the analyticity of fz along whatever path you integrate from say z_1 to z_2 , the value of the integral does not depend on the geometric shape of the path, it remains the constant, it only depends on the points z_1 and z_2 not on the geometric shape of the path.

But the function $fz = \text{real } z$ here actually, is not analytic, so such a thing has happened.

(Refer Slide Time: 37:32)

Example 4

Evaluate

$$\int_C f(z) dz,$$

where $f(z) = z^2 + 3z^{-4}$ and C is the upper half of the unit circle from $(1, 0)$ to $(-1, 0)$.

$$\int_C f(z) dz = \int_0^\pi \left((e^{i\theta})^2 + 3e^{-4i\theta} \right) e^{i\theta} i d\theta$$

$$= i \int_0^\pi (e^{3i\theta} + 3e^{-3i\theta}) d\theta$$

$$= i \left[\frac{e^{3i\theta}}{3i} + 3 \frac{e^{-3i\theta}}{-3i} \right]_0^\pi = \frac{1}{3} \left[e^{3i\pi} - 3e^{-3i\pi} \right]$$

$$= \frac{1}{3} [-1 + 3 - 1 + 3] = \frac{4}{3}$$

$C: |z|=1, 0 \leq \theta \leq \pi$
 $\Rightarrow z = e^{i\theta}$
 $\frac{dz}{d\theta} = e^{i\theta} i$

Handwritten notes on the left:

$$e^{3i\theta} = \cos 3\theta + i \sin 3\theta$$

$$e^{-3i\theta} = \cos 3\theta - i \sin 3\theta$$

At $\theta = \pi$, $e^{3i\pi} = -1$, $e^{-3i\pi} = -1$

Now, let us consider another example, integral over C fz dz , where $fz = z$ square + $3z$ to the power -4 , where C is upper half of the unit circle from $z = 1$ to $z = -1$, let us draw the curve first, so this is your unit circle, mod of $z = 1$, this centre is 0 and radius is 1 , okay, we are

considering C is the upper half of the unit circle from $1 + 0i$, this is $1 + 0i$ point, so $1 + 0i$ to $-1 + 0i$, so we have to integrate fz along the upper half.

So, this is parameter, so C is $|z| = 1$, the parametric form is $z = e^{i\theta}$ and θ varies here from, θ is 0 here at $1 + 0i$ and at $-1 + 0i$ θ is π , okay, so θ varies from 0 to π , this is our curve C , okay. So, $\int_C f(z) dz = \int_0^\pi f(z) \frac{dz}{d\theta} d\theta$, when z is replaced by $z = e^{i\theta}$, so $e^{i\theta}$ whole square + 3 times $e^{i\theta}$ to the power $-4i\theta$ and dz replace by $\frac{dz}{d\theta}$; $\frac{dz}{d\theta}$ is $e^{i\theta} \cdot i$.

So, this is $e^{i\theta} \cdot i$, so what we get here then; $\int_0^\pi e^{2i\theta} \cdot e^{i\theta} \cdot i$, this i can write it outside, so $i \int_0^\pi e^{3i\theta} d\theta$. Now, this is $i \left[\frac{e^{3i\theta}}{3i} \right]_0^\pi = \frac{1}{3} [e^{3i\pi} - e^0]$.

So, this i can cancel with this i and I get $\frac{1}{3} [e^{3i\pi} - 1]$; okay, so what I get; $\frac{1}{3} [e^{3i\pi} - 1]$, I can write outside, okay this $\frac{1}{3}$, and this 3 , so $e^{3i\pi} + 3$ times, so -3 $e^{3i\pi}$, okay and then we put the lower limit, so $- e^0$ that is 1 and then we get $+3$ e^0 that is 1 , okay. So, $e^{3i\pi} = \cos 3\pi + i \sin 3\pi$, $\cos 3\pi$ is $\cos 2\pi + \pi$ which is $\cos \pi$, so $\cos \pi = -1$ and $\sin 3\pi = 0$.

So, I get -1 here, $e^{3i\pi}$ will be $\cos 3\pi - i \sin 3\pi$ and this is also -1 , so what I get; $\frac{1}{3} [-1 - (-1)] = 0$, so I get here 0 , then here I get 3 here, then $-1 + 3$, so this is $\frac{4}{3}$, so this is the value of the line integral of $f(z) = z^2 + 3z^{-4}$ along the unit circle from the point $1 + 0i$ to the point $-1 + 0i$ that is all in this lecture, thank you very much for your attention.
