Lecture - 14
Gram Schmidt Process

Hello friends. Welcome to lecture number 14 of this course on Essential Mathematics for Machine Learning. Today, we will discuss about Gram Schmidt Process. It is a process from which we can transform a set of l vectors to a set of orthogonal vectors or in fact, orthonormal vectors.

Because, you know in many basis we require orthonormal basis and therefore, this process is really very important, when you need those kind of orthonormal or orthogonal basis because, you can transform any basis to orthogonal or orthonormal using this process.

(Refer Slide Time: 01:06)

Orthogonal Sets

Let V be a vector space with an inner product $\langle \cdot, \cdot \rangle$.

Definition: Nonzero vectors $v_1, v_2, \dots, v_k \in V$ form an orthogonal set if they are orthogonal to each other i.e. $\langle v_i, v_j \rangle = 0$ for $i \neq j$.

If, in addition, all vectors are of unit norm, $\|v_i\| = 1$, then v_1, v_2, \dots, v_k forms an orthonormal set.

Theorem: Any orthogonal set is linearly independent.

 VT ROORKEE  NPTEL ONLINE
CERTIFICATION COURSE 2

So, first let me define the orthogonal sets. However, many times we have gone through this definition, but just to recall you that let be V be a vector space with an inner product. So, basically V is an inner product space here nonzero vectors v_1, v_2, v_k . So, these are k vectors from the inner product space capital V . They, form an orthogonal set if they are orthogonal to each other.

It means, the inner product of $v_i v_j$ equals to 0, whenever i not equals to j . If in addition all vectors are of unit norm that is the inner product of a vector v_i with itself equals to 1, for all i 1 to k . Then it is called an orthonormal set, means v_1, v_2, v_k are forming an orthonormal set. Again if you are having orthogonal set, then it will be linearly independent, but reverse is or converse is not true. So, if you are having a set of k vectors that is orthogonal; obviously, those k vectors will be linearly independent.

(Refer Slide Time: 02:20)

Orthogonal Projection

Theorem: Let V be an inner product space and V_0 be a finite-dimensional subspace of V . Then any vector $x \in V$ is uniquely represented as $x = p + o$, where $p \in V_0$ and $o \perp V_0$.

The component p is the orthogonal projection of the vector x onto the subspace V_0 . The distance from x to the subspace V_0 is $\|o\|$.

If $\{v_1, v_2, \dots, v_n\}$ is an orthogonal basis for V_0 then

$$p = \frac{\langle x, v_1 \rangle}{\langle v_1, v_1 \rangle} v_1 + \frac{\langle x, v_2 \rangle}{\langle v_2, v_2 \rangle} v_2 + \dots + \frac{\langle x, v_n \rangle}{\langle v_n, v_n \rangle} v_n$$

NPTEL ONLINE

9

Now, we you have seen this theorem already in orthogonal projection, but we have to recall it in a wider setting means, where we are talking about a subspace. So, let V be an inner product space and V_0 be a finite dimensional sub space of V . So, what V is an inner product space and V_0 is a finite dimensional sub space of V .

Then any vector X belongs to V is uniquely represented as X equals to p plus o , where p is a vector in V_0 and o is a vector which is perpendicular to V_0 that is V_0 complement. The component p is the orthogonal projection of vector X onto the subspace V_0 . The distance from X to the subspace V_0 is given by the length of this vector o because, it is a perpendicular distance.

So obviously, it will be distance from X to the subspace V_0 . If v_1, v_2, v_n is an orthogonal basis for V_0 , then you can calculate very easily p . So, p will become $X \cdot v_1$

and the inner product of X with v_1 upon v_1 norm multiplied with vector v_1 , then inner product of X with v_2 . So, what it is giving you the component of the vector X in V^\perp subspace.

(Refer Slide Time: 04:03)

So, you can see by this graphic, so, you are having this vector X and this is the subspace V^\perp . So, what is p ? So, p is the component of X in subspace V^\perp and o is the perpendicular component. So, I can write this X as p plus o and that I can write it uniquely, where p is a vector in V^\perp as you can see here in this V^\perp subspace and o is perpendicular to p or even all the vectors lie in the subspace V^\perp .

And hence distance of X can be given by this and that is the length of the vector o . So, these are some results which we have seen earlier also in the orthogonal projection lecture. Now, we will use these results to find out a process by which we can convert a set of linearly

independent vectors to a set of orthogonal vectors. And that process is called Gram Schmidt process.

(Refer Slide Time: 05:15)

Gram-Schmidt Process:-

Let V be an inner product space. Suppose x_1, x_2, \dots, x_n is a basis of V . Now, let

$$v_1 = x_1;$$

$$v_2 = x_2 - \frac{\langle x_2, v_1 \rangle}{\langle v_1, v_1 \rangle} v_1$$

$$v_3 = x_3 - \frac{\langle x_3, v_1 \rangle}{\langle v_1, v_1 \rangle} v_1 - \frac{\langle x_3, v_2 \rangle}{\langle v_2, v_2 \rangle} v_2$$

$$\vdots$$

$$v_n = x_n - \frac{\langle x_n, v_1 \rangle}{\langle v_1, v_1 \rangle} v_1 - \frac{\langle x_n, v_2 \rangle}{\langle v_2, v_2 \rangle} v_2 - \dots - \frac{\langle x_n, v_{n-1} \rangle}{\langle v_{n-1}, v_{n-1} \rangle} v_{n-1}$$

Then $\{v_1, v_2, \dots, v_n\}$ is an orthogonal set.

$$\begin{aligned} \langle v_1, v_2 \rangle &= \langle x_1, x_2 - \frac{\langle x_2, x_1 \rangle}{\langle x_1, x_1 \rangle} x_1 \rangle \\ &= \langle x_1, x_2 \rangle - \langle x_2, x_1 \rangle \\ &= 0 \end{aligned}$$

So, let V be an inner product space. Suppose, x_1, x_2, x_n is a basis of V . So, these are the vectors in V and they form a basis of V . So, better I write it in this way; so, x_1, x_2 and x_n since they are vectors.

So, now since x_1, x_2, x_n are basis of V , so, they are linearly independent. Now, I want to convert the set of vectors X containing the vectors x_1, x_2, x_n into a set of vectors those are orthogonal. So, now let v_1 equals to x_1 . So, whatever first vector you are having here that I have written as such. Now, I want to make second vector v_2 and I want that this vector v_2 should be orthogonal to v_1 that is your x_1 .

So, for making it orthogonal what I need? I need to separate the component of in the direction of X_1 from the vector X_2 . Means whatever component of X_2 is there in the direction of X_1 , if I subtract that from X_2 then what will happen? After subtraction whatever vector you are getting that will be perpendicular or orthogonal to X_1 . So, I will use this concept only. So, v_2 equals to X_2 and now from X_2 , I will subtract the component of X_2 that is in direction of X_1 .

So, how I will do it? I will write like this. $X_2 - v_1 \text{ upon } v_1 \text{ into } v_1$ means, I am subtracting in the direction of X_1 that is your v_1 only into so, in the direction of v_1 so into v_1 . So, if you notice this is the component of X_2 in the direction of v_1 . And I am subtracting this from X_2 . So, what now v_2 does not have any component in direction of v_1 .

That is component in the direction of v_1 is 0. Hence v_2 and v_1 are perpendicular that you can see here also. If you find out v_1, v_2 that will become v_1 is your X_1 and this is X_2 minus $X_2 \cdot X_1 \text{ upon } X_1$, X_1 into X_1 . So, this will become X_1, X_2 by this minus X_1, X_1 will be canceled out X_2, X_1 and this is 0. So, inner product of v_1 and v_2 is 0, so, they are orthogonal.

Similarly, I will go for third vector v_3 . So, v_3 will be again I will subtract from X_3 the component of X_3 in the direction of v_1 and v_2 . So, it will become $X_3, v_1 \text{ upon } v_1, v_1$ into v_1 minus $X_3, v_2 \text{ upon } v_2, v_2$ into v_2 . And I will go in the same way, X_4 like that and finally, for v_n I will be having X_n minus $X_n \cdot v_1 \text{ upon } v_1, v_1$ multiplied with vector v_1 minus $X_n \cdot v_2$ and so on.

And finally, I will be having X_n, v_n minus v_n minus v_n minus v_n into v_n minus 1. And as you have seen here v_1, v_2 are orthogonal, similarly v_3 will be orthogonal to v_1 and v_2 and so on. Then what I can write? v_1, v_2, v_n is an orthogonal set. So, this process of finding another set which is orthogonal from a given linearly independent set is called Gram Schmidt process.

Now, what is important here? Important is since x_1, x_2, \dots, x_n is a basis of V , so, they span the vector space V , the question is whether this new set v_1, v_2, \dots, v_n is also spanning the vector space V . Yes, the span of x_1, x_2, \dots, x_n equals to span of v_1, v_2, \dots, v_n . We can easily prove it.

(Refer Slide Time: 12:32)

The slide contains handwritten notes on a blue background. At the top, a box labeled 'Any basis' with x_1, x_2, \dots, x_n inside has an arrow pointing to a box labeled 'Orthogonal basis' with v_1, v_2, \dots, v_n inside. Below this, the word 'Properties:-' is written. A list of five properties follows, each in a circle:

- (i) $v_k = x_k - (\alpha_1 x_1 + \dots + \alpha_{k-1} x_{k-1})$ for $1 \leq k \leq n$
- (ii) $\text{span}(v_1, v_2, \dots, v_k) = \text{span}(x_1, x_2, \dots, x_k)$
- (iii) v_k is orthogonal to x_1, x_2, \dots, x_{k-1}
- (iv) $v_k = x_k - p_k$, where p_k is the orthogonal projection of the vector x_k on the subspace spanned by x_1, x_2, \dots, x_{k-1}
- (v) $\|v_k\|$ is the distance from x_k to the subspace spanned by x_1, x_2, \dots, x_{k-1}

At the bottom left, there are logos for 'swayam' and 'NPTEL'. At the bottom right, the number '2' is visible.

So, what we have seen? Any basis x_1, x_2, \dots, x_n we apply the Gram Schmidt process on it. And then we got the orthogonal basis v_1, v_2, \dots, v_n , where v_1 equals to x_1 , v_2 equals to x_2 minus the component of x_2 in the direction of v_1 .

Similarly, v_3 will be x_3 minus the component of x_3 in direction of v_1 minus the component of x_3 in direction of v_2 and so on, like we have seen it on the previous slide. Now, some properties. So, first property is here v_k will be x_k minus $\alpha_1 x_1$ plus $\alpha_{k-1} x_{k-1}$ for 1 to k to n . As you and what is α_1 ? α_1 will be inner product of x_k

with v_1 upon v_1, v_1 ; inner product of v_1 with itself and so on. So, these are the scalar coefficients.

Now, second is a span of v_1, v_2, v_K equals to span of x_1, x_2, x_k . And this you can prove by this one easily by using this particular thing. Now, third one is v_K is orthogonal to x_1, x_2 up to x_{k-1} ; number 4 v_K equals to x_k minus p_K . So, what I can write? Where p_K is the orthogonal projection of the vector x_K on the subspace spanned by x_1, x_2, x_{K-1} .

And what is this? The length of v_K that is norm of v_K is the distance and what distance? Shortest distance, from x_k to the subspace spanned by x_1, x_2, x_{k-1} . So, we can make in this way. So, these are some properties very easy to remember and easily verify from the Gram Schmidt process.

(Refer Slide Time: 17:18)

$$\begin{aligned}
 \Rightarrow \quad v_1 &= x_1, \quad w_1 = \frac{v_1}{\|v_1\|} \\
 v_2 &= x_2 - \langle x_2, w_1 \rangle w_1 \quad \text{and} \quad w_2 = \frac{v_2}{\|v_2\|} \\
 v_3 &= x_3 - \langle x_3, w_1 \rangle w_1 - \langle x_3, w_2 \rangle w_2 \quad \text{and} \quad w_3 = \frac{v_3}{\|v_3\|} \\
 &\vdots \\
 v_n &= x_n - \langle x_n, w_1 \rangle w_1 - \dots - \langle x_n, w_{n-1} \rangle w_{n-1} \\
 w_n &= v_n / \|v_n\| \\
 \Rightarrow \{w_1, w_2, \dots, w_n\} &\text{ is an orthonormal set.}
 \end{aligned}$$

Now, if you write like this just the same process. What we were doing? We are writing v_1 equals to X_1 and, then what you do? You write w_1 equals to v_1 upon norm of v_1 . Then what you are doing? You are calculating v_2 .

So, v_2 you write X_2 minus X_2 with w_1 into w_1 . So, what, the same thing because w_1 is having unit length. So, I am not writing denominator here. So, same thing which we have done earlier only thing in terms of unit vectors. And then what you do? Define w_2 equals to v_2 upon norm of v_2 . So, w_2 again a unit vector then v_3 will become X_3 minus X_3 w_1 multiplied with w_1 minus inner product of X_3 with w_2 multiplied by with w_2 .

And then w_3 you define v_3 upon norm of v_3 . If you go in this way finally, you will be having v_n that is X_n minus X_n w_1 multiplied with the inner product of X_n and w_1 with w_1 minus and finally, inner product of X_n with w_{n-1} multiplied this scalar with w_{n-1} . And, then define w_n equals to v_n upon norm of v_n .

Then what you will be having? This side w_1, w_2, w_n span the same set which is spanned by v_1, v_2, v_n or X_1, X_2, X_n and it is a orthonormal set. So, in previous slide we have seen about orthogonalization process using Gram Schmidt, but here we have just modified it in case when you need orthonormal set. So, now we will see some of the examples how to implement this process for finding the orthogonal or orthonormal basis.

(Refer Slide Time: 20:09)

Ex.1: Let P be a plane in \mathbb{R}^3 spanned by the vectors $X_1 = (1, 2, 2)$ and $X_2 = (-1, 0, 2)$. $-\frac{4}{3} + \frac{4}{3} = 0$

- (i) Find an orthonormal basis for P .
- (ii) Extend it to a basis of \mathbb{R}^3 .

Soln: Here, X_1, X_2 and $X_3 = (0, 0, 1)$ be a basis of \mathbb{R}^3

Now $v_1 = X_1$ and $w_1 = \frac{v_1}{\|v_1\|} = \frac{1}{3}(1, 2, 2) \checkmark$

$$v_2 = X_2 - \langle X_2, w_1 \rangle w_1 = (-1, 0, 2) - 1 \cdot \frac{1}{3}(1, 2, 2) = \left(-\frac{4}{3}, -\frac{2}{3}, \frac{4}{3}\right)$$

$$w_2 = \frac{v_2}{\|v_2\|} = \frac{1}{3}(-2, -1, 2) \checkmark$$

$\{w_1, w_2\}$ forms an orthonormal basis of P .

So $v_3 = X_3 - \langle X_3, w_1 \rangle w_1 - \langle X_3, w_2 \rangle w_2$

$$= (0, 0, 1) - \frac{2}{3}w_1 - \frac{2}{3}w_2 = \frac{1}{3}(2, -2, 1)$$

$$w_3 = \frac{1}{3}(2, -2, 1) \checkmark$$

So, let us do example 1. So, let P be a plane in \mathbb{R}^3 spanned by the vectors X_1 equals to 1, 2, 2 and X_2 equals to minus 1, 0, 2.

So, now first find an orthonormal basis for the subspace P and the second thing extend it to a basis of \mathbb{R}^3 . So, we can solve this problem using 2 way; 1, first we will solve this one that we will find an orthonormal basis for P using the Gram Schmidt process on X_1 and X_2 . And, then we take a vector orthonormal to w_1 and w_2 which is coming using after applying the Gram Schmidt process.

And, then it will become the basis of \mathbb{R}^3 or you first take a li vector to X_1 and X_2 let us say X_3 and then apply the Gram Schmidt process. So, let us solve it. So, let X_1, X_2 and X_3

which is you just take \mathbf{v}_1 to \mathbf{x}_1 and \mathbf{x}_2 . So, I am taking $\mathbf{v}_1, \mathbf{v}_2, \mathbf{v}_3$ be a basis of \mathbb{R}^3 . So, I have added extend the basis of which \mathbf{x}_1 and \mathbf{x}_2 of P to a basis of \mathbb{R}^3 .

Now, so in fact it is not let here, now \mathbf{v}_1 will be your \mathbf{x}_1 . And then \mathbf{w}_1 will become \mathbf{v}_1 . So, what is norm of \mathbf{v}_1 ? It will become $\sqrt{1^2 + 3^2 + 1^2 + 2^2 + 2^2}$. Then I will be having \mathbf{v}_2 that is your \mathbf{x}_2 minus \mathbf{x}_2 inner product of \mathbf{x}_2 with \mathbf{w}_1 , multiplied with \mathbf{w}_1 .

So, here inner product is usual dot product in \mathbb{R}^3 . So, \mathbf{x}_2 is $[-1, 0, 2]$ minus dot product of \mathbf{x}_2 with \mathbf{w}_1 ; so, $[-1, 0, 2] \cdot [1, 3, 1, 2, 2]$. So, $-1 \cdot 1 + 0 \cdot 3 + 2 \cdot 1 = 1$. So, \mathbf{x}_2 minus $1 \cdot [1, 3, 1, 2, 2]$ and \mathbf{w}_1 is $[1, 3, 1, 2, 2]$. So, $[-1, 0, 2] - [1, 3, 1, 2, 2] = [-2, -3, 1, 0, 0]$; so, $[-2, -3, 1, 0, 0]$ and then $\sqrt{2^2 + 3^2 + 1^2} = \sqrt{14}$, so, $[-2/\sqrt{14}, -3/\sqrt{14}, 1/\sqrt{14}, 0, 0]$.

Now, calculate \mathbf{w}_2 ; \mathbf{w}_2 will become \mathbf{v}_2 upon norm of \mathbf{v}_2 . So, this will become $1/\sqrt{14} [-2, -3, 1, 0, 0]$. So, $[-2/\sqrt{14}, -3/\sqrt{14}, 1/\sqrt{14}, 0, 0]$. So, $\sqrt{14}$ and $\sqrt{14}$ square root will become 2. So, it will become $1/\sqrt{14} [-2, -3, 1, 0, 0]$ because I have to divide by $\sqrt{14}$ and 2. So, this is your $\mathbf{w}_1, \mathbf{w}_2$. And now $\mathbf{w}_1, \mathbf{w}_2$ forms an orthonormal basis of P .

Now, what is orthonormal basis of \mathbb{R}^3 ? So, I will calculate \mathbf{v}_3 ; so, \mathbf{v}_3 will become \mathbf{x}_3 minus \mathbf{x}_3 inner product with \mathbf{w}_1 multiplied with \mathbf{w}_1 minus inner product of \mathbf{x}_3 with \mathbf{w}_2 and that scalar multiplied with \mathbf{w}_2 .

So, \mathbf{x}_3 is here $[0, 0, 1]$ minus inner product of \mathbf{x}_3 with \mathbf{w}_1 and so on and after calculating it, I will get $[1, 3, 2, -2, 1]$; so, that will be \mathbf{w}_3 . So, whatever \mathbf{v}_3 I will get means, I have to divide means it will be $1/\sqrt{14} [1, 3, 2, -2, 1]$ and then \mathbf{w}_3 will become length of this that is $\sqrt{14}$; so, $[1/\sqrt{14}, 3/\sqrt{14}, 2/\sqrt{14}, -2/\sqrt{14}, 1/\sqrt{14}]$. So, here this $\mathbf{w}_1, \mathbf{w}_2$ and \mathbf{w}_3 forms an orthonormal basis of \mathbb{R}^3 .

So, in that way we can apply the Gram Schmidt process for finding the orthonormal basis for any subspace of a given vector space, or we can apply it for finding the orthonormal or orthogonal basis for a complete vector space; means. vector space of any dimension. That is finite dimension, but not for infinite dimension.

So, in this lecture we have learned how to solve or how to form an orthogonal or orthonormal basis for a vector space using the Gram Schmidt process. In the next lecture we will learn another important decomposition of matrices that is polar decomposition. In that decomposition what we usually have? We used to have a complex number like, polar form of a complex number like a decomposition of a given matrix, in form of an isometry and a positive definite matrix, so.

Thank you very much.
