Lecture - 19
Minimal Polynomial and Jordan Canonical Form

Hello friends. So, welcome to the module of the course Essential Mathematics for Machine Learning. And the module name is Minimal Polynomial and Jordan Canonical Form. So, again it is very important topic from matrix story and we will see it is a generalization of what we have learn earlier that is of the diagonalization.

(Refer Slide Time: 00:48)

Minimal Polynomial

Definition

For a matrix $A \in \mathbb{R}^{n \times n}$, the minimal polynomial $m_A(\lambda)$ is a unique monic polynomial of minimal degree such that $m_A(A) = \mathbf{0}$.

We can say that if for any polynomial $f(\lambda)$, we have $f(A) = \mathbf{0}$ if and only if $f(\lambda) = m_A(\lambda) \cdot q(\lambda)$ for a polynomial $q(\lambda)$.

2

So, first we will discuss about minimal polynomial. So, the definition we can state like this, so for a matrix A which is n by n real matrix the minimal polynomial denoted by m_A of λ .

So, it is a polynomial of λ is a unique monic polynomial of minimal degree, such that $m_A(A)$ equals to 0 matrix.

Means this polynomial annihilate the matrix A . One of such polynomial you know about the characteristic polynomial; however, if you are having a n by n matrix, then the degree of characteristic polynomial is n , whereas if we talk about the minimal polynomial it is having degree n or less than n .

So, based on that we can say if for any polynomial $f(\lambda)$, we have $f(A)$ equals to 0, if and only if $f(\lambda)$ is the product of minimal polynomial of A into another polynomial q . So, it means if a polynomial f annihilate the matrix A , then the minimal polynomial divides that particular polynomial. Now, see the example consider this 2 by 2 diagonal matrix.

(Refer Slide Time: 02:18)

Minimal Polynomial Example

Example-1

For the matrix

$$A = \begin{bmatrix} 2 & 0 \\ 0 & 2 \end{bmatrix}$$

The characteristic polynomial is $c_A(\lambda) = (\lambda - 2)^2$, while the minimal polynomial is $m_A(\lambda) = (\lambda - 2)$.

Example-2

For the matrix

$$A = \begin{bmatrix} 2 & 1 \\ 0 & 2 \end{bmatrix}$$

The characteristic polynomial is $c_A(\lambda) = (\lambda - 2)^2 = m_A(\lambda)$.

3

So, the characteristic polynomial of this is nothing just the lambda minus 2 whole square, while the minimal polynomial is lambda minus 2 because this particular polynomial annihilate the matrix.

(Refer Slide Time: 02:46)

$$\begin{aligned}
 A &= \begin{bmatrix} 2 & 0 \\ 0 & 2 \end{bmatrix} ; \quad M_A(A) = A - 2I = O_{2 \times 2} \\
 &\Rightarrow m_A(\lambda) = (\lambda - 2) \checkmark \\
 &\quad c_A(\lambda) = (\lambda - 2)^2
 \end{aligned}$$

$$\begin{aligned}
 A_2 &= \begin{bmatrix} 2 & 1 \\ 0 & 2 \end{bmatrix} \quad c_{A_2}(\lambda) = (\lambda - 2)^2 \\
 &\quad m_{A_2}(\lambda) = (\lambda - 2)^2 \checkmark
 \end{aligned}$$

$$\begin{aligned}
 A - 2I &= \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix} \neq O_{2 \times 2} \\
 (A - 2I)^2 &= O_{2 \times 2}
 \end{aligned}$$

$$\begin{aligned}
 &2\lambda^3 - \lambda^2 + 4\lambda - 8 \\
 &\quad \lambda^3 - \frac{1}{2}\lambda^2 + 2\lambda - 4
 \end{aligned}$$

Here A equals to 2 0 0 2, then m A of A becomes A minus 2 I and this is equals to 0 2 by 2 null matrix. It means the minimal polynomial of A is given by lambda minus 2. While the characteristic polynomial of A is lambda minus 2 whole square.

So, if you observe here, here this minimal polynomial is having less degree when compare to characteristic polynomial as well as it is monic. Now, what is the meaning of monic? Monic means the leading coefficient of the polynomial is 1 and it is a polynomial of single variable.

So, for example, if you are having a particular polynomial, let us say $2\lambda^3 - \lambda^2 + 4\lambda - 8$, then it is not monic. However, the monic form of this will become the leading coefficient that is the coefficient of highest degree term that is λ^3 here is 1.

So, in that way it will become $\lambda^3 - 2\lambda^2 + 2\lambda - 4$. Another important thing about monic polynomial is that, it is a polynomial of single variable that it is a polynomial of λ only.

So, if you take another example let us say I take another matrix A which is $\begin{pmatrix} 2 & 1 & 0 & 2 \end{pmatrix}$, then what we can say here again characteristic polynomial of this matrix is $\lambda - 2$ whole square. And if we see the minimal polynomial of this matrix then it is again the same as the characteristic polynomial that is $\lambda - 2$ square.

Here if you simply take $A - 2I$ which becomes $\begin{pmatrix} 0 & 1 & 0 & 0 \end{pmatrix}$ and it is not a null matrix of size 2 by 2. However, if you take $(A - 2I)^2$ it becomes 0 matrix of size 2 by 2.

So, here $\lambda - 2$ square is the monic polynomial which is having the least degree. And annihilate the matrix A hence the minimal polynomial is $\lambda - 2$ whole square. So, I hope with these two examples the concept or definition of minimal polynomial is clear to all of you.

(Refer Slide Time: 06:06)

Minimal Polynomial Result

If A and B are square matrices, $A \oplus B$ is defined to be square matrix

$$A \oplus B = \begin{bmatrix} A & \mathbf{0} \\ \mathbf{0} & B \end{bmatrix}$$

and is called the *direct sum* of the matrices A and B .

If $C = A \oplus B$, where A and B are square matrices then

1.

$$c_C(\lambda) = c_A(\lambda) \cdot c_B(\lambda)$$

2. The minimal polynomial $m_C(\lambda)$ of the matrix C is the least common multiple of $m_A(\lambda)$ and $m_B(\lambda)$.

Now, come to a very important result about minimum polynomial that if A and B are square matrices, then $A \oplus B$ is defined to be square matrix of this form means, where a diagonal sum matrices is A and B and rest of the entries are coming from the 0 matrices of corresponding sizes. Now, this $A \oplus B$ is called the direct sum of the matrices A and B .

(Refer Slide Time: 06:45)

$$A = \begin{bmatrix} 2 & 0 \\ 0 & 2 \end{bmatrix} \quad \text{and} \quad B = \begin{bmatrix} 2 & 1 \\ 0 & 2 \end{bmatrix}$$

$$C = A \oplus B = \left[\begin{array}{cc|cc} 2 & 0 & 0 & 0 \\ 0 & 2 & 0 & 0 \\ \hline 0 & 0 & 2 & 1 \\ 0 & 0 & 0 & 2 \end{array} \right]_{4 \times 4} \quad \checkmark$$

$$C_C(\lambda) = (\lambda - 2)^2 \cdot (\lambda - 2)^2 = (\lambda - 2)^4$$

$$m_C(\lambda) = \text{L.C.M.}(m_A(\lambda), m_B(\lambda))$$

$$= (\lambda - 2)^2 \checkmark$$

So, for example, if you take A equals to the same 2 0 0 2 and B equals to 2 1 0 2, then A plus B that is the direct sum of A and B is 2 0 0 2. This is one of the diagonal matrix and another one is 2 1 0 2 and rest of the entries are 0.

So, it becomes 4 by 4 matrix, now what we will see that if C is a direct sum of A and B, where A and B are square matrices then the characteristic polynomial of C is just the product of the characteristic polynomials of A and B, while the minimal polynomial of C is the least common multiple of the minimal polynomials of A and minimal polynomial of B.

So, if this is I am saying let us say C. So, here characteristics polynomial of C is given by the product of characteristic polynomial of A and B. So, it is nothing just lambda minus 2 raise to power 4. While minimum polynomial of C is the least common multiple of minimal polynomial

of A and minimal polynomial of B. The minimum polynomial of A is $\lambda - 2$, while the minimal polynomial of B is $(\lambda - 2)^2$.

So, L.C.M comes out to be $(\lambda - 2)^2$. So, here you can see if we talk about this 4 by 4 matrix here characteristic polynomial; obviously, is of degree 4, while the minimal polynomial is of degree 2.

So, this is I want to say about minimal polynomial, we will see the definition of Jordan Blocks and then Jordan Canonical Forms and then we will come back the relation of minimal polynomial with Jordan form.

(Refer Slide Time: 09:31)

Jordan Canonical Form

We know that a given square matrix of order $n \times n$ is diagonalizable if and only if it has n linearly independent eigenvectors.

Since, not all $n \times n$ matrices are diagonalizable, the Jordan Canonical Form (JCF) gives a more general similarity transformation.

5

So, now come to Jordan Canonical form. So, we know that a given square matrix of order n by n is diagonalizable, if and only if it has n linearly independent eigenvectors.

So, if the number of linearly independent eigenvectors equals to the size of matrix then, matrix is similar to a diagonal matrix where diagonal entries are eigen values. However, if this is not the case means if an n by n matrix is not diagonalizable means it is having less than n linearly independent eigenvectors.

Then the Jordan Canonical Form gives a more general similarity transformation. So, what we can say that diagonalization is a special case of Jordan Canonical Transformation.

(Refer Slide Time: 10:33)

Ex: $A_1 = \begin{bmatrix} 7 & 2 \\ -4 & 1 \end{bmatrix}$ then $\lambda = 5, 3$

X_1 (eigenvector corresponding to $\lambda = 5$)
 $\Rightarrow X_1 = (1, -1)^T$

$X_2 = (1, -2)^T$

$A_1 = P D P^{-1}$
 where
 $P = \begin{bmatrix} 1 & 1 \\ -1 & -2 \end{bmatrix}$ and $D = \begin{bmatrix} 5 & 0 \\ 0 & 3 \end{bmatrix}$

So, let us understand it with the help of an example. So, let us have a matrix A_1 which is a 2 by 2 matrix and entries of A_1 is 7 2 minus 4 1.

Then if you calculate the eigen values of A_1 it comes out to be λ equals to 5 and 3. Now the eigenvector corresponding to, this I am saying eigenvector corresponding to λ

equals to 5. So, here X_1 comes out to be $\begin{bmatrix} 1 \\ 1 \end{bmatrix}$ transpose. Similarly if X_2 is the eigenvector corresponding to the eigen value λ equals to 3 then X_2 comes out to be $\begin{bmatrix} 1 \\ -2 \end{bmatrix}$.

So, X_1 and X_2 are linearly independent because they are eigenvectors corresponding to distinct eigen value. Hence what I can do? I can write A^{-1} as $P D P^{-1}$, means A^{-1} is similar to a diagonal matrix D , where P is a matrix which is having column says the eigenvector of A^{-1} that is 1. And minus 1 is the first column that is your eigenvector X_1 and then second one is 1 and minus 2.

And here D equals to $\begin{bmatrix} 5 & 0 & 0 \\ 0 & 3 & 0 \end{bmatrix}$. Here just note that why I am taking 5 here because I have written the eigenvector corresponding to λ equals to 5 as the first column. If you interchange these two columns then D will become $\begin{bmatrix} 3 & 0 & 0 \\ 0 & 5 & 0 \end{bmatrix}$.

And if you calculate $P D P^{-1}$ it comes out to be A^{-1} . So, this is an example of the diagonalization and we have learned it earlier also in this course; however, you consider another matrix.

(Refer Slide Time: 13:11)

Ex: $A_2 = \begin{bmatrix} 1 & 1 \\ 0 & 1 \end{bmatrix}$ $\lambda = \underline{1, 1}$

$(A-I)X = 0 \Rightarrow \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix} \Rightarrow x_2 = 0$
 and x_1 is arb.

$X = (1, 0)^T$

$\times A_2 = P D P^{-1}$

$\checkmark A_2 = S J S^{-1}$

$\downarrow \quad \downarrow$

A.M. of $\lambda=1$ is 2
 G.M. of $\lambda=1$ is 1
 $A.M. > G.M.$

Let me take a matrix A_2 which is given by $\begin{bmatrix} 1 & 1 & 0 & 1 \\ 0 & 1 & 0 & 0 \end{bmatrix}$. Now it is a upper triangular matrix; so obviously eigen values are λ equals to 1 and 1. Now, if you see the eigenvector corresponding to λ equals to 1 then I can write A minus λI , λ is 1 here into X equals to 0.

So, it means $1 - 1$ is 0, $\begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \end{bmatrix}$ and then X is a vector in $\mathbb{R}^2 \times 1 \times 2$ equals to $\begin{bmatrix} 0 \\ 0 \end{bmatrix}$. So, from here what I am getting x_2 equals to 0 and x_1 is arbitrary. So, from here I can write X equals to $\begin{bmatrix} 1 \\ 0 \end{bmatrix}$. So, what you are observing here we are having 2 eigen values means of this matrix both are equal that is λ equals to 1; however, corresponding to 1 we are having only one eigenvector.

So, this matrix cannot be write as A_2 equals to $P D P$ inverse because how to form this model matrix P , because we are having only one eigenvector. So, we cannot have this kind of

diagonalization of this matrix A^2 hence we have to see a more general version for writing this kind of similarity Transformation.

So, here role of Jordan Canonical Transformation comes we write $A^2 = S J S^{-1}$ where S is again a matrix which is coming from the eigenvectors and generalized eigenvectors of A^2 , while J is the Jordan Canonical Form of the matrix A^2 . J is not a diagonal matrix here; however, it is having diagonal entries.

And one at super diagonal in some of the blocks, we will learn about it. Now, another important thing here I want to tell you that algebraic multiplicity and geometric multiplicity.

So, here eigen value λ equals to 1 is repeating twice. So, here algebraic multiplicity of λ equals to 1 is 2 that is the number of repetition of that particular eigen value. While geometric multiplicity is the number of linearly independent corresponding to that eigenvalue. So, how many eigenvectors I am having for λ equals to 1 that is only 1.

So, algebraic multiplicity is the count of the repetition of eigen values. While the geometric multiplicity is the number of corresponding linearly independent eigenvectors. Here you can notice that the geometric multiplicity never exceeds algebraic multiplicity.

Now, if I talk about algebraic multiplicity and geometric multiplicity then I can write that, a matrix is diagonalizable only when algebraic multiplicity equals to geometric multiplicity. If it is not equal means algebraic multiplicity greater than geometric multiplicity for one or more eigen values of a matrix, then we have to go for Jordan Canonical Transformation.

(Refer Slide Time: 17:44)

JCF definition

Jordan Block

A Jordan Block $J_k(\lambda)$ is a $k \times k$ matrix with λ on the main diagonal and 1 on the super diagonal.

$$J_1(\lambda_0) = [\lambda_0]; \quad J_2(\lambda_0) = \begin{bmatrix} \lambda_0 & 1 \\ 0 & \lambda_0 \end{bmatrix}; \quad J_3(\lambda_0) = \begin{bmatrix} \lambda_0 & 1 & 0 \\ 0 & \lambda_0 & 1 \\ 0 & 0 & \lambda_0 \end{bmatrix}$$

In general

$$J_k(\lambda_0) = \begin{bmatrix} \lambda_0 & 1 & 0 & 0 & \cdots \\ 0 & \lambda_0 & 1 & 0 & \cdots \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & 0 & \lambda_0 & 1 \\ 0 & 0 & 0 & 0 & \lambda_0 \end{bmatrix}_{k \times k}$$

So, that is the motivation behind learning the Jordan Canonical Transformation. So, before going to Jordan Canonical Transformation let us learn about Jordan blocks.

So, a Jordan Blocks $J_k(\lambda)$, here k is the size of the block and it is corresponding to eigen value λ is a k by k matrix with λ on the main diagonal and 1 on the super diagonal. For example, a Jordan block of size 1 corresponding to eigen value λ_0 is just λ_0 , A 1 by 1 matrix that, it is a Jordan block of size 1.

Similarly, a Jordan block is size 2 can be written as $\begin{bmatrix} \lambda_0 & 1 \\ 0 & \lambda_0 \end{bmatrix}$ a Jordan block of size 3 $\begin{bmatrix} \lambda_0 & 1 & 0 \\ 0 & \lambda_0 & 1 \\ 0 & 0 & \lambda_0 \end{bmatrix}$ like this. So, here you can notice we are having the eigen value at the main diagonal and at the super diagonal we are having 1. Similarly a Jordan block of size k giving by this one.

(Refer Slide Time: 18:47)

Properties of Jordan Block

- 1 A Jordan block has only one eigenvalue $\lambda = \lambda_0$ with algebraic multiplicity k i.e $\text{Det}(J_k(\lambda_0) - \lambda I_k) = (\lambda - \lambda_0)^k$
- 2 Geometric multiplicity of $\lambda = \lambda_0$ is 1.
- 3 If $e_1, e_2, \dots, e_n$ denotes the standard basis in n -dimensional space, then $J_k(\lambda_0)e_1 = \lambda_0 e_1$; $J_k(\lambda_0)e_i = \lambda_0 e_i + e_{i-1}$ for $i = 2, \dots, k$.

7

Now, if we talk about some of the important properties of Jordan block, then a Jordan block has only one eigen value that is lambda equals to lambda 0.

With algebraic multiplicity k that is the size of the Jordan block, the geometric multiplicity of lambda equals to lambda 0 is 1. Furthermore if $e_1, e_2, \dots, e_n$ denotes by standard basis in n dimensional space, then if you operate the Jordan block corresponding to eigen value lambda 0 on e_1 it equals to lambda 0 e_1 , that is it is saying you that lambda 0 is an eigen value with algebraic multiplicity k of the Jordan block.

Furthermore $J_k(\lambda_0)$ if you operate it on any e_i then it equals to lambda 0 e_i plus e_{i-1} minus 1. So, what I want to say from these properties that is first property is if you consider this.

(Refer Slide Time: 19:58)

$$\begin{aligned} \textcircled{1} \quad I_2(2) \begin{bmatrix} 2 & 1 \\ 0 & 2 \end{bmatrix} = J & \quad C_J(\lambda) = (\lambda - 2)^2 \\ \textcircled{3} \quad J e_1 = \begin{bmatrix} 2 & 1 \\ 0 & 2 \end{bmatrix} \begin{bmatrix} 1 \\ 0 \end{bmatrix} = \begin{bmatrix} 2 \\ 0 \end{bmatrix} = 2 e_1 \\ J e_2 = \begin{bmatrix} 2 & 1 \\ 0 & 2 \end{bmatrix} \begin{bmatrix} 0 \\ 1 \end{bmatrix} = \begin{bmatrix} 1 \\ 2 \end{bmatrix} = 2 \begin{bmatrix} 0 \\ 1 \end{bmatrix} + \begin{bmatrix} 1 \\ 0 \end{bmatrix} \end{aligned}$$

Let us say we have taken this matrix earlier also $\begin{bmatrix} 2 & 1 & 0 & 2 \end{bmatrix}$. So, it is a Jordan block of size 2, corresponding to eigen value λ . So, here characteristic polynomial of this if I say it let say J simply $C_J(\lambda)$ is nothing just $\lambda - 2$ square.

So, the eigen value of the Jordan block is 2 with algebraic multiplicity equals to 2. Similarly if I say about the geometric multiplicity of this the geometric multiplicity of a Jordan block equals to 1.

So, if you are having a eigen a Jordan matrix which is having different eigen values or if you are having a Jordan block which having the same eigen value.

Then based on this particular concept which I told you that the geometric multiplicity corresponding to an eigen value λ of a specific Jordan block will be 1, tells you about

how to write Jordan Canonical Form of a matrix. We will see in this example further in this lecture later on and furthermore what I want to say, if you are having this $J \in \mathbb{R}^2$.

That is we are e_1 is a standard basis in $\mathbb{R}^2$ a vector of the standard basis. Then it is $\begin{pmatrix} 2 & 1 \\ 0 & 2 \end{pmatrix}$ and what is standard basis in $\mathbb{R}^2$, e_1 will be $\begin{pmatrix} 1 \\ 0 \end{pmatrix}$, e_2 will be $\begin{pmatrix} 0 \\ 1 \end{pmatrix}$, then it comes out to be $2e_1$ and is 2 times e_1 . Similarly $J e_2$ is $\begin{pmatrix} 2 & 1 \\ 0 & 2 \end{pmatrix} \begin{pmatrix} 0 \\ 1 \end{pmatrix}$ and then $\begin{pmatrix} 1 \\ 2 \end{pmatrix}$, here what we are having it comes out to be e_1 and then $2e_2$. So, this is equals to $2e_2 + e_1$ that is $e_1 + 2e_2$, this is the third property.

(Refer Slide Time: 23:44)

Definition

JCF

A Jordan Canonical Form is a block diagonal $n \times n$ matrix:

$$J = \begin{bmatrix} J_{k_1}^{\lambda_1} & 0 & 0 & 0 & \cdots \\ 0 & J_{k_2}^{\lambda_2} & 0 & 0 & \cdots \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & 0 & J_{k_{m-1}}^{\lambda_{m-1}} & 0 \\ 0 & 0 & 0 & 0 & J_{k_m}^{\lambda_m} \end{bmatrix}_{n \times n}$$

with m Jordan Blocks $J_{k_1}^{\lambda_1}, J_{k_2}^{\lambda_2}, \dots, J_{k_{m-1}}^{\lambda_{m-1}}, J_{k_m}^{\lambda_m}$ corresponding to $\lambda_1, \lambda_2, \dots, \lambda_m$ such that $k_1 + k_2 + \dots + k_{m-1} + k_m = n$ and 0 denotes a zero matrix.

8

Now, when we talk about Jordan Canonical form, so Jordan Canonical Form is a matrix which is having many Jordan Blocks. So, formally we can define it a Jordan Canonical Form is a block diagonal matrix of size n in this form $J_{k_1}^{\lambda_1}, J_{k_2}^{\lambda_2}, \dots, J_{k_m}^{\lambda_m}$.

So, here $J_{k_1}(\lambda_1)$ is a Jordan block corresponding to eigen value λ_1 and size is k_1 . Similarly for this one and so on, with m Jordan Blocks as I told you corresponding to eigen values $\lambda_1, \lambda_2, \lambda_3, \dots, \lambda_m$ such that $k_1 + k_2 + \dots + k_m = n$, that is the size of the matrix and 0 denotes a zero matrix.

(Refer Slide Time: 23:39)

Properties of JCF

- 1. $\text{Det}(J - \lambda I) = (\lambda_1 - \lambda)^{k_1} (\lambda_2 - \lambda)^{k_2} (\lambda_3 - \lambda)^{k_3} \dots (\lambda_m - \lambda)^{k_m}$
Proof/Hint : Can be obtained by calculating the determinant of an upper triangular matrix.
- 2. The Jordan Canonical Form has m eigenvectors $X_1, X_2, X_3, \dots, X_m$, each corresponds to λ on the Jordan Block.
Proof/Hint: By induction on the number of Jordan blocks. You can use the property that all eigenvectors of J can be chosen orthogonal.

9

So, here if you are having a matrix a Jordan Canonical Form J , then determinant of this matrix is given by $(\lambda_1 - \lambda)^{k_1} (\lambda_2 - \lambda)^{k_2} \dots (\lambda_m - \lambda)^{k_m}$, that is coming from the first Jordan block, second Jordan block and so on.

So, it is the product of characteristic polynomial of each Jordan block. The Jordan Canonical Form has m eigenvectors because each Jordan block gives you only one linearly independent eigenvector, here we are having m Jordan Blocks. So, m eigenvectors $X_1, X_2, X_3, \dots, X_m$ each.

(Refer Slide Time: 24:22)

Examples:

① $A = \begin{bmatrix} 1 & 1 & 1 \\ 0 & 1 & 1 \\ 0 & 0 & 1 \end{bmatrix}$

Eigenvalue of A is $\lambda = 1$ with A.M. 3

Eigenvector corresponding to $\lambda = 1$ is

$$(A - I)X = 0 \Rightarrow X = (1, 0, 0)^T$$

G.M. of $\lambda = 1$ is 1

Hence, JCF of A is

$$J = \begin{bmatrix} 1 & 1 & 0 \\ 0 & 1 & 1 \\ 0 & 0 & 1 \end{bmatrix}; \quad A = \underline{S} J \underline{S}^{-1}$$

Corresponding to lambda on the Jordan block so, let us take some example of Jordan Canonical Form. So, let us take a matrix A equals to 1 1 1 0 1 1 0 0 1, then eigen value of this matrix. So, eigen value of A is lambda equals to 1 with algebraic multiplicity 3.

Now eigenvector corresponding to lambda equals to 1 is A minus I, X equals to 0 and this comes out to be X equals to 1 0 0.

So, hence geometric multiplicity of lambda equals to 1 is 1. So, it cannot be diagonalized. So, we have to go for Jordan Canonical transformation, but before that how to write Jordan Canonical Form of A, hence Jordan Canonical Form in short I am writing JCF of A is.

So, you see here geometric multiplicity gives you the number of Jordan Blocks. So, what is the number of Jordan Blocks corresponding to lambda equals to 1 that is 1. And what is

algebraic multiplicity algebraic multiplicity tells you that what will be the total size of the Jordan Blocks corresponding to eigen value lambda equals to 1.

So, here 1 Jordan block and size is 3. So, what will be Jordan Canonical Form $\begin{bmatrix} 1 & 1 & 0 \\ 0 & 1 & 1 \\ 0 & 0 & 1 \end{bmatrix}$. And then we will find out a matrix S such that A equals to S J S inverse. We will see how to find out this matrix s in next lecture.

(Refer Slide Time: 27:14)

② $B = \begin{bmatrix} 1 & 0 & 1 \\ 0 & 1 & 1 \\ 0 & 0 & 1 \end{bmatrix}$; $\lambda = 1, 1, 1$
 Eigenvalue $\lambda = 1$ is of A.M. 3
 $(B - I)X = 0$
 $X = (1, 0, 0)^T$ and $(0, 1, 0)^T$
 G.M. of $\lambda = 1$ is 2
 $3 = 1 + 2$ or $2 + 1$
 $J = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 1 \\ 0 & 0 & 1 \end{bmatrix} \sim \begin{bmatrix} 1 & 1 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$

However, if you take another example let us say another matrix B which is $\begin{bmatrix} 1 & 0 & 1 & 0 & 1 & 1 \\ 0 & 1 & 0 & 0 & 0 & 0 \end{bmatrix}$, then again eigen value lambda equals to 1 is of algebraic multiplicity 3 because eigen value is 1 repeating three times.

Now, if you find out the eigenvectors corresponding to lambda equals to 1 then you have to solve B minus lambda I, X equals to 0. And in the null space of B minus I we are having two

alive solutions means, analytics 2 of $B - I$ and those 2 vectors are X equals to $\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \end{pmatrix}^T$, you can check you can calculate it.

So, now geometric multiplicity of λ equals to 1 is 2. So, here you will be having two Jordan Blocks and total size of those two Jordan Blocks will be sum will be 3. So, how you will decompose 3 in 2 blocks? So, obviously 1 plus 2 or 2 plus 1; so what will be Jordan Canonical Form?

So, here a block of size 1 another block of size 2. So, $\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$, this is a block of size 1 and then $\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$, or first this Jordan block of size 2, $\begin{pmatrix} 1 & 1 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$. So, it is a Jordan block of size 1.

I forgot to write here $\begin{pmatrix} 0 & 0 \\ 0 & 0 \end{pmatrix}$ and then here you are having of size 1. So, this is a Jordan Canonical form of B ; however, generally we consider these two are same up to reordering of the Jordan Blocks.

So, in this lecture we have learned the definition of minimal polynomial, then we have learned about the Jordan Blocks and how to write the Jordan Canonical Form of a given matrix, based on it is eigen values and eigenvectors, basically based on the algebraic multiplicity and geometric multiplicity. In the next lecture we will learn about Jordan Canonical transformation, so with this.

Thank you very much.
