Lecture – 24
Properties of Convex Functions – I

Hello friends. Welcome to lecture series on Essential Mathematics for Machine Learning. In the last lecture we have seen that what convex sets and convex functions are, their geometric interpretation also we have seen. Now, we will see some of the basic Properties of Convex Functions in this lecture.

(Refer Slide Time: 00:42)

The slide is titled "Properties of Convex functions" in a blue header. Below the header, there is a section titled "Theorems" in a blue box. It contains two theorems, each preceded by a blue circle with a white number. The first theorem states: "Let $S \subseteq \mathbb{R}^n$ be a convex set. If $f : S \rightarrow \mathbb{R}$ is convex, then any local minimum of f in S is a global minimum on S ." The second theorem states: "Let $S \subseteq \mathbb{R}^n$ be a convex set and $f : S \rightarrow \mathbb{R}$ be strictly convex. Then, there is a unique minimizing point of f over S ." At the bottom of the slide, there is a blue footer containing logos for IIT Roorkee, Swayam, and NPTEL, along with the number 2.

Properties of Convex functions

Theorems

- ① Let $S \subseteq \mathbb{R}^n$ be a convex set. If $f : S \rightarrow \mathbb{R}$ is convex, then any local minimum of f in S is a global minimum on S .
- ② Let $S \subseteq \mathbb{R}^n$ be a convex set and $f : S \rightarrow \mathbb{R}$ be strictly convex. Then, there is a unique minimizing point of f over S .

   2

So, the first and most property of convex function is that if you have a convex function f from a convex set to \mathbb{R} , then to take any local minimum of f in S that is a global minimum ok. So that means, if in the if in a small neighbourhood you have find a local minimum and you know

that the function is a convex function, then that local minimum is nothing, but a global minimum.

This is a property of; this is a peculiar property of a convex function ok. So, let us try to see that what is the proof of this theorem. So, we have seen that what convex functions are that we have already seen.

(Refer Slide Time: 01:28)

So, what do you mean by local minimum? Suppose, \bar{x} is a point of local minimum local minimum of f on S . So, what does it mean? So, it is a local minimum, local minimum means that if you have such type of function; local minimum means if you take a small neighbourhood. In their small neighbourhood if this is \bar{x} then the small neighbourhood, the value of this function if the function is of minimizing type; that means, the value of the function that of \bar{x} is always less than equal to $f(x)$, for every x in this small neighbourhood.

So, this implies $f(\bar{x})$ is always less than equal to $f(x)$ for every x belongs to δ neighbourhood of \bar{x} ; that means, the small neighbourhood of \bar{x} ok. And of course, this x is in S so, intersection with S . So, if I am saying that \bar{x} is a local minimum of f on S ; that means, $f(\bar{x})$ is always less than equal to $f(x)$ for every x in δ neighbourhood of \bar{x} intersection with S . And, if \bar{x} we are saying it is the global minimum; what does it mean?

Global minimum of f on S ; so, this means that $f(\bar{x})$ is less than equal to $f(x)$ for every x in S . So, if you are taking in entire S that this inequality is holding; that means, global minimum. And, if you are taking in a small neighbourhood for some δ greater than 0, if you are taking a small neighbourhood a intersection with S that this inequality is holding; that means, local minimum.

(Refer Slide Time: 03:33)

Proof: let f be convex function on S . let \bar{x} be a point of local minimum of f .

$\Rightarrow \exists \delta > 0$ such that

$$f(\bar{x}) \leq f(x), \quad \forall x \in N_\delta(\bar{x}) \cap S \quad (1)$$

Suppose \bar{x} is not a point of global minimum.

$\Rightarrow \exists \hat{x} \in S$ such that

$$f(\hat{x}) < f(\bar{x}) \quad (2)$$

So, in that in that statement suppose \bar{x} is a local minimum. So, let us try to prove that theorem; let f be a convex function on S . Now, now let \bar{x} be a point of local minimum of f ; if \bar{x} is a point of local minimum; that means, this implies that there exists some δ greater than 0 such that $f(\bar{x}) \leq f(x)$ for all x belongs to δ neighbourhood of \bar{x} intersection with S .

So, suppose this expression is 1. Now, we have to show that \bar{x} is nothing, but a point of global minimum. So, we will try to prove the result by a method of contradiction. So, let us suppose \bar{x} is not a point of global minimum. So, suppose \bar{x} is not a point of global minimum.

So, if it is not a point of global minimum; that means, there exists some point x in S where value of $f(x)$ is still less than $f(\bar{x})$, because \bar{x} is not a point of global minimum. So, this implies that there exist some say \hat{x} belongs to S such that $f(\hat{x}) < f(\bar{x})$, suppose it is 2. Now, still we have not used convex function, the definition of convex function. So, let us try to include that also in the proof, then only we can obtain the contradiction.

(Refer Slide Time: 05:47)

Let $x = \lambda \hat{x} + (1-\lambda) \bar{x}$, $0 < \lambda < 1$
 $\exists \bar{\lambda}$, $0 < \bar{\lambda} < 1$, such that
 $\bar{x} = \bar{\lambda} \hat{x} + (1-\bar{\lambda}) \bar{x} \in N_\delta(\bar{x}) \cap S$.
 $f(\bar{x}) = f(\bar{\lambda} \hat{x} + (1-\bar{\lambda}) \bar{x})$
 $\leq \bar{\lambda} f(\hat{x}) + (1-\bar{\lambda}) f(\bar{x})$
 $< \bar{\lambda} f(\bar{x}) + (1-\bar{\lambda}) f(\bar{x}) = f(\bar{x})$
 This contradicts (1). Hence, \bar{x} is a point
 of global minimum of f on S .

The slide includes a diagram of a set S (shaded region) and a point \bar{x} with a neighborhood $N_\delta(\bar{x})$ (circle) intersecting S . A point \hat{x} is shown outside S , and a line segment connects \hat{x} to \bar{x} within the neighborhood.

Let x equal to λx cap plus 1 minus λx bar where, λ between 0 and 1 . So, suppose this is region S , suppose this is S ok. Suppose this is some x cap, this is some x bar and this is a small neighbourhood of x bar for some δ this radius is δ and this is some x cap ok. So, in this in this neighbourhood, in this neighbourhood $f x$ bar is always less than or equal to $f x$ for every x belongs to δ neighbourhood x bar and for this x cap $f x$ cap is less than $f x$ bar.

Now, now this as clc this is x , clc of these two point. Now, there will always exist some λ no matter how small λ maybe, but there will always exist some λ between 0 and 1 such that this clc will get a point at least 1 which such that this point belongs to δ neighbourhood of $f x$ bar δ neighbourhood of x bar. So, we can say that there will always

exist $\sum \lambda$, λ between 0 and 1 such that x which is clc of these two points belongs to δ neighbourhood of \bar{x} intersection with S ok.

Because it is \bar{x} and it is $\sum \lambda x$; so, there will always exist some λ such that x is x belongs to this neighbourhood. Now, let us take $f x$. What will be $f x$? $f x$ will be f of $\lambda x + (1 - \lambda) \bar{x}$ and since function is convex. So, this is less than equals to $\lambda f x + (1 - \lambda) f \bar{x}$. What we are having from 2? $f x$ is less than $f \bar{x}$.

So, this is less than $\lambda f \bar{x} + (1 - \lambda) f \bar{x}$ which is equal to $f \bar{x}$ ok. So that means, now where this x is? This x is in δ neighbourhood of \bar{x} ok, this x is in you can take this \tilde{x} ; this \tilde{x} is in for some λ between 0 and 1. So, some λ sorry this is λ , you have taken λ . For some λ between 0 and 1, this \tilde{x} is in δ neighbourhood of \bar{x} .

So, we have shown that $f \tilde{x}$ is less than $f \bar{x}$, but from 1 $f \bar{x}$ is always less than equal to $f x$ for every x in δ neighbourhood. But, we have find the x in δ neighbourhood where this inequality is reversed; that means, \bar{x} is not a point of local minimum. So, this is this contradicts our assumption that this is not a global minimum. Hence, we can see hence we can say that \bar{x} is a point of global minimum.

So, this implies this contradicts 1 and hence \bar{x} is a point of global minimum of f on S . So, so we can say that if we have a convex function and we have find the local minimum then that local minimum is nothing, but a global minimum of f . The next result is that, if this function is a strictly convex then that local minimum is local minimum is global of course, but that is unique.

In this case for a normal convex function it may not be unique, but for if a function is strictly convex it is unique. So, let us try to prove this also.

(Refer Slide Time: 10:31)

f is a strictly convex function on S .
Suppose $\bar{x} \in S$ is a global minimum point of f .
Let \bar{x} be not a unique point.
 $\Rightarrow \exists \hat{x} \in S, \bar{x} \neq \hat{x}, f(\bar{x}) = f(\hat{x})$.
 $z = \lambda \bar{x} + (1-\lambda) \hat{x}, 0 < \lambda < 1, z \in S$
 $f(z) = f(\lambda \bar{x} + (1-\lambda) \hat{x})$
 $< \lambda f(\bar{x}) + (1-\lambda) f(\hat{x})$
 $= \lambda f(\hat{x}) + (1-\lambda) f(\hat{x})$
 $= f(\hat{x}) \Rightarrow f(z) < f(\hat{x})$
 $\Rightarrow \bar{x}$ is a unique global minimum point of f on S .

So, now it is given to us that f is a strictly convex function on S and we have to show that global minimum is unique ok. Suppose, \bar{x} is a point of global minimum, global minimum point of f \bar{x} belongs to S ok. So, let \bar{x} be not be not a unique point; be not a unique point ok. So; that means, this implies that there exists some \hat{x} belongs to S , \bar{x} not equal to \hat{x} such that $f(\bar{x})$ is equals to $f(\hat{x})$.

Because if it is not unique; that means, there will exist some other point also which is global minimum distinct from \bar{x} such that $f(\bar{x})$ is equals to $f(\hat{x})$. Now, you take you take say z which is $\lambda \bar{x} + 1 - \lambda \hat{x}$, λ between 0 and 1 ok. Now, if you take $f(z)$; so, $f(z)$ is nothing, but f of $\lambda \bar{x} + 1 - \lambda \hat{x}$.

So, it is equals to $\lambda f(\hat{x}) + (1-\lambda) f(\bar{x})$ so, but these two are equal; these two are equal; that means so, here it is function is strictly convex. So, this

will be this will be strictly less than this. So, this is further equal to because $f(\bar{x})$ is equal to $f(x^*)$. So, it is λ times $f(x^*)$ plus $1 - \lambda$ times $f(x^*)$. So, this after simplification we get $f(x^*)$.

So, this implies $f(z)$ is less than $f(x^*)$. So, this contradicts that x^* is global minimum point ok; because there is a z of course, this z belongs to S because S is a convex set. So, this we have a point z on S such that $f(z)$ is less than $f(x^*)$; that means, this x^* is not a point of global minimum.

So, this is a contradiction and hence \bar{x} is a unique global minimum point of f on S ok. So, we have seen that if we have a convex function then if you take any local minimum that is global and if function is strictly convex then this global minimum is unique.

(Refer Slide Time: 14:02)

Differentiable functions

- Let $f : S \rightarrow \mathbb{R}$ be **differentiable** at $\bar{x} \in S$, where S is an open subset of \mathbb{R}^n . Then for $x + \bar{x} \in S$,

$$f(x + \bar{x}) = f(\bar{x}) + x^T (\nabla f(\bar{x})) + \alpha(\bar{x}, x) \|x\|$$

where $\lim_{x \rightarrow 0} \alpha(\bar{x}, x) = 0$.
- Let $f : S \rightarrow \mathbb{R}$ be **twice differentiable** at $\bar{x} \in S$, where S is an open subset of \mathbb{R}^n . Then for $x + \bar{x} \in S$,

$$f(x + \bar{x}) = f(\bar{x}) + x^T (\nabla f(\bar{x})) + \frac{1}{2} x^T \nabla^2 f(\bar{x}) x + \beta(\bar{x}, x) \|x\|^2$$

where $\lim_{x \rightarrow 0} \beta(\bar{x}, x) = 0$.

3

Now, let us see some other properties of convex functions. So, this we will use in this other theorems. So, you just have to recall this definition. So, if a function is differentiable at \bar{x} belongs to S , where S is an open subset of \mathbb{R}^n . Then for any x plus \bar{x} belongs to S we have this by Taylor's theorem that f of $\bar{x} + x$ is equal to f of \bar{x} plus x transpose gradient of f at \bar{x} plus $\frac{1}{2} x^T \nabla^2 f(\bar{x}) x$ where this will tends to 0 as $\|x\|$ tends to 0.

If function is once differentiable and if it is given to us twice differentiable then this definition will extend up to second derivative; I means Hessian matrix. And, then it is plus $\frac{1}{2} x^T \nabla^2 f(\bar{x}) x$ where this will tends to 0 as $\|x\|$ tends to 0. So, this we will use if it is given to us that the function is once differentiable or twice differentiable accordingly in the proof.

(Refer Slide Time: 15:18)

Theorem

Let $f : S \rightarrow \mathbb{R}$ be differentiable function on an open convex subset S of \mathbb{R}^n . Then f is a convex function if and only if

$$f(x_1) - f(x_2) \geq (x_1 - x_2)^T \nabla f(x_2) \quad \forall x_1, x_2 \in S.$$

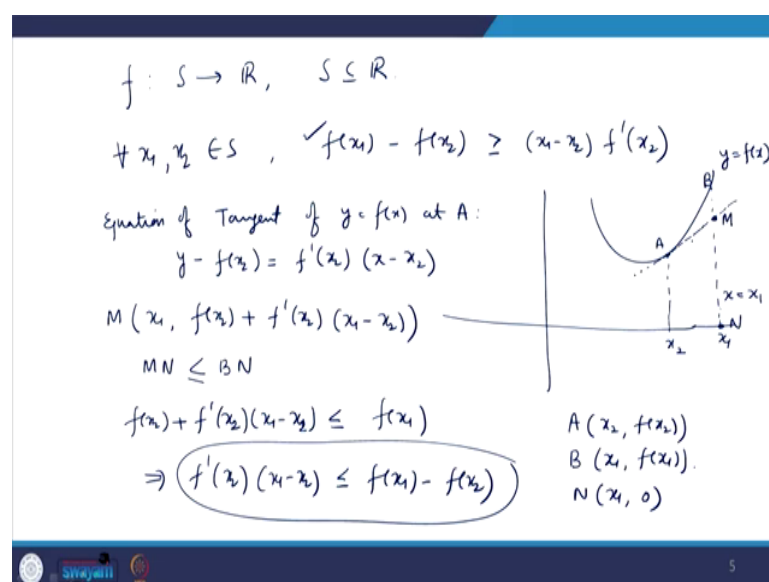

4

Now, we have the next result on convex function which is an important result and we will use to we will try to we will use this result in proving other properties of convex functions. But, in point of in the view of machine learning the proof of this theorem is not so important. We will try to simply see the geometric interpretation of this result ok.

So, first we will see what this theorem is basically. So, if function is once differentiable on an open convex subset S of \mathbb{R}^n . Then f is convex if and only if; that means, both side if f is convex then this holds and if this holds then f is convex, then this result hold. So, what do you mean by this? We will just understand it by geometrically.

(Refer Slide Time: 16:05)

So, suppose function is from S to \mathbb{R} , where S is a sub set of \mathbb{R} ok. So, this property will be nothing but for every $x_1 \geq x_2$ in S . So, this is basically $f(x_1) - f(x_2)$ is greater than equals to $(x_1 - x_2) f'(x_2)$ ok. So, this is the same property if I am talking if here S

is in \mathbb{R}^n subset of \mathbb{R}^n , I am taking S is subset of \mathbb{R} to understand the geometric interpretation of this property ok.

So, now, let us take a function this, let us take a point say this point is say x_2 , say this point is x_1 . So, this is A point, suppose this is B point. So, what are coordinates of A point? A point is say this function is y equal to $f(x)$. So, coordinate of A point will be x_2 comma a of $f(x_2)$ and coordinate of B point will be x_1 comma $f(x_1)$ ok. Now, you draw a tangent at this point ok.

So, what is a equation of tangent at A; equation of tangent of y equal to $f(x)$ at A? That will be $y - y_1 = f'(x_1)(x - x_1)$ ok. This is a equation of this tangent. Now, what this point will be? Suppose, this point is M; now this tangent intersection of the tangent this and the line x equal to x_1 , this line is x equal to x_1 .

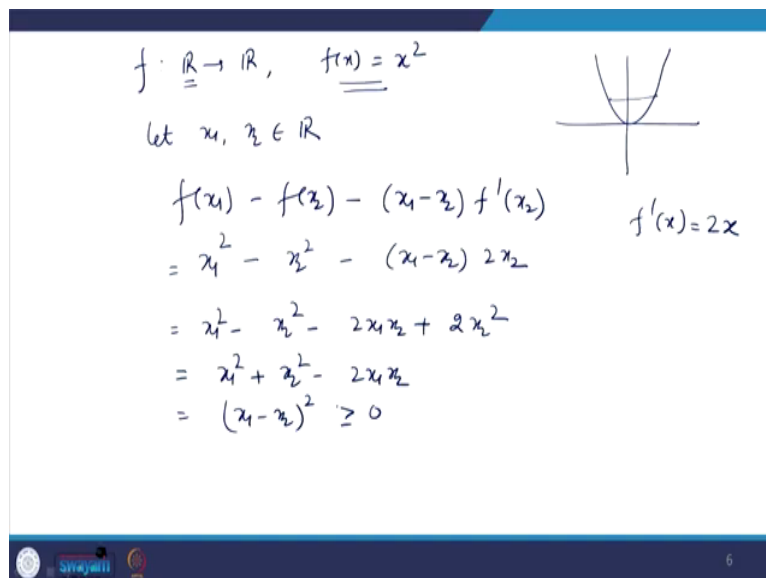

The intersection of these two line give this point M. So, the point M will be x is x_1 and what will be y for point M? For point M, you simply substitute x equal to x_1 find y . So, this is $f(x_2) + f'(x_1)(x_1 - x_2)$ ok. So, we got this point. Now, you can clearly see that this if this point is suppose N, this point if suppose this point is N. So, where N point is x_1 comma 0 so, you can see that MN , MN is less than BN .

And, if it is a straight line, it may hold as an equation also ok. So, what is MN ? MN is basically MN means y coordinate of M point this height; that means, y coordinate of this point this height. So, y coordinate this point is what? $f(x_2) + f'(x_1)(x_1 - x_2)$ is less than equal to BN , BN means y coordinate of B point; y coordinate of B point is what? $f(x_1)$.

So, this implies $f(x_2) + f'(x_1)(x_1 - x_2) \leq f(x_1)$; that means, the same; that means, the same point which we are having here. So, so what we can say geometrically? So, geometrically we can say that that if you draw a tangent at any point on a convex function, then tangent is always below the curve or on the curve if it is a straight line. Here it is, this function is strictly convex.

So, that is why this is always lie below the curve. But, if it is a function like boat shape function then it may lie on the curve also. So; that means, if you are having a convex function, if you draw a tangent at any point; the tangent will lie either below the curve or on the curve always. So, that is another important interesting property of convex functions.

(Refer Slide Time: 20:50)

$$\begin{aligned}
 f: \mathbb{R} &\rightarrow \mathbb{R}, \quad f(x) = x^2 \\
 \text{let } x_1, x_2 &\in \mathbb{R} \\
 f(x_1) - f(x_2) - (x_1 - x_2)f'(x_2) &= x_1^2 - x_2^2 - (x_1 - x_2)2x_2 \\
 &= x_1^2 - x_2^2 - 2x_1x_2 + 2x_2^2 \\
 &= x_1^2 + x_2^2 - 2x_1x_2 \\
 &= (x_1 - x_2)^2 \geq 0
 \end{aligned}$$

$f'(x) = 2x$

So, suppose function is given to say function is from \mathbb{R} to \mathbb{R} and function is defined as say $f(x)$ equal to x square. You want to show that this function is convex ok. I mathematically, geometrically you know; geometrically you know that this function is a convex function. Because if you draw any two point join the chord, chord is always above the curve.

So, this function is always convex; I mean is a convex function. But if you want to show mathematically; so, you can use this property. What this property is? This property means for if you take let x_1, x_2 are any point in S in \mathbb{R} , here S is \mathbb{R} ok; then by then by this property you

have to show this inequality holds. So, you can bring this expression on the left hand side and try to show that the entire expression is greater than equal to 0, for any x_1, x_2 .

So, let us let us try to see, you take $f(x_1) - f(x_2) - x_1 - x_2 f'(x_2)$. And what we have to show? We have to show that this expression is greater than equal to 0; if you have shown this then by this theorem we can say that the given function is a convex function. So, so let us try to see what is x_1 , what is $f(x_1)$?

$f(x_1)$ is x_1 square by this definition, x_2 is x_2 square minus x_1 minus x_2 . What is $f'(x_1)$, $f'(x_2)$? $f'(x)$ is $2x$; so, it is $2x_2$. So, this is further equal to x_1 square minus x_2 square minus $2x_1x_2$ minus minus plus $2x_2$ square. So, this is equals to x_1 square plus x_2 square minus $2x_1x_2$. So, this is equal to $(x_1 - x_2)^2$ and this is always greater than equal to 0 for all for any x_1, x_2 in \mathbb{R} .

So, in this way we have shown analytically also that the given function is a convex function. Similarly, if you take other examples say e^x ; so, using the same concept, using the same definition you can show easily show that the given function is a convex function ok.

(Refer Slide Time: 23:15)

So, geometrically we have already discussed this thing. So, in this lecture we have seen that the two important properties of convex function. Number 1, that every local minimum is global minimum and the second property is the if a function is once differentiable and a function is convex it is given to you, then then this inequality then then this inequality hold ok.

In the next lecture, we will see few more properties of convex functions.

Thank you.
